ANTIMERIA, in *Grammar*, a figure whereby one part of speech is used for another; e. g., *velle suum cuique est*, for *voluntas sua cuique est*; also *populus late rex*, for *populus late regnans*. In a more restricted sense, it denotes a figure where the noun is repeated instead of the pronoun. This figure is frequent in the Hebrew, and is sometimes retained in our version of the Old Testament: e. g., *Hear my voice, ye wives of Lamech*,—for *my wives*. Gen. iv. 23.

ANTIMONY, a metal very rarely found pure in nature, but generally as a sulphuret, to which indeed the name of Stibium, or Στιμμι, was applied by the ancients; and the sulphuret, it is said, from a preparation of it having proved fatal to the monks of a German convent, afterwards ob-

Antinomians ‖ Antinous.

tained the name of antimony—*quasi, anti monachos.* Whether this be true or not, this name soon became general for the sulphuret, and is now applied to the pure metal.

Antimony has a white colour, with nearly the lustre of silver when fresh; but it tarnishes slowly when freely exposed. Its specific gravity is only 6·7, and it melts at 810° F. On cooling, it shows a tendency to crystallise, and assumes a foliated texture. When moderately heated in the open air, it catches fire, and burns with a bright bluish-white flame. It is brittle, and easily pounded.

It unites with oxygen into a white oxide, now generally employed for obtaining antimonial medicines, especially emetic tartar, which is a tartrate of antimony and potash. The metal forms several compounds with sulphur; the most important of which is the black sulphuret, the ore from which antimony is always obtained for the arts. This substance, as we have said, was the ancient Stibium, and is the material applied ages ago by the women of Eastern countries to give increased lustre to their eyes by darkening the eyelashes. The *paint* said in the Holy Scriptures to have been used by Jezebel, seems to have been this substance; for St Jerome, who knew the manners of Eastern women, has, in the Vulgate, rendered the passage "*oculos ejus posuit stibio.*" All our antimonial preparations were formerly made directly from the sulphuret; and it was used to form alloys before its true nature was understood. The pure metal was *then* termed regulus of antimony, and under this name it is mentioned in the *Currus Antimonii Triumphalis* of Basil Valentinus, a German monk and alchemist.

Alloys of antimony with other metals are of value. It is added to gold in ornamental work, to give variety of colour; it is added to bell-metal to increase the sonorous quality of the compound; it is alloyed with lead and tin to give hardness and solidity to type-metal; a small addition of it to 11 parts of tin and 4 of copper, improves the quality of specula for telescopes, and enables the compound to receive a higher polish. See CHEMISTRY. (T. S. T.)

ANTINOMIANS, in *Ecclesiastical History*, certain heretics who maintain that the law is of no use or obligation under the gospel dispensation, or who hold doctrines that clearly supersede the necessity of good works and a virtuous life. The Antinomians took their origin from John Agricola about the year 1538, who taught that the law is nowise necessary under the gospel; that good works do not promote our salvation, nor ill ones hinder it; that repentance is not to be preached from the Decalogue, but only from the Gospel.

This sect sprung up in England during the protectorate of Oliver Cromwell, and extended their system of libertinism much further than Agricola. Some of their teachers expressly maintained, that as the elect cannot fall from grace, nor forfeit the divine favour, the wicked actions they commit are not really violations of the Divine law; and that, consequently, they have no occasion either to confess their sins, or break them off by repentance.

The doctrine of Agricola was in itself obscure, and perhaps represented as worse than it really was by Luther, who wrote with acrimony against him, and first styled him and his followers *Antinomians.* Agricola stood on his own defence, and complained that opinions were imputed to him which he did not hold. Nicholas Amsdorf fell under the same odious name and imputation, and seems to have been treated more unfairly than even Agricola himself.

ANTINOUS, a beautiful Bithynian youth, celebrated as the favourite of the Emperor Hadrian, who paid the most extravagant honours to his memory. Antinous was drowned in the Nile, and near the spot where he perished, on the site of the ancient Besa, the emperor founded a city which he named *Antinoopolis.* At Mantinēa in Arcadia a temple was erected to Antinous, in which he was worshipped as a deity, and there, and at Bithynium, his birthplace, Hadrian instituted annual sacrifices and quinquennial games, called *Antinoeia.* A constellation into which his soul was supposed to have passed still bears his name.

Antioch.

The death of Antinous (about the year 122) constitutes an era in the history of art, from the stimulus given to sculpture by the demand for busts and statues commemorative of his extraordinary beauty. Many of these are extant. They are supposed to be of Grecian execution, though wrought in Italian marble. (Levezow, *Ueber den Antinous*, &c.; Berlin, 1801.)

ANTIOCH, a city of Syria, in Asia, on the River Orontes, in Long. 36. 10. E. Lat. 36. 11. N. It was built by Seleucus Nicator, founder of the Syro-Macedonian empire, who made it his capital. It stood on the above-mentioned river, about 20 miles from the place where it falls into the Mediterranean, being equally distant from Constantinople and Alexandria in Egypt, that is, about 700 miles from each. Seleucus called it *Antioch*, from his father's name according to some, or, according to others, from that of his son. He built in all sixteen cities bearing the same name, of which one was situated in Pisidia. But that situated on the Orontes by far eclipsed not only all the others of this name, but all the cities built by Seleucus; and is probably that where the name of Christians was first given to the followers of Jesus Christ. Antigonus, not long before, had founded a city in that neighbourhood, which from his own name he had called Antigonia, and designed it for the capital of his empire; but it was razed to the ground by Seleucus, who employed the materials in building his metropolis, and also transplanted the inhabitants thither.

Antioch was afterwards known by the name of Tetrapolis, being divided as it were into four cities, each surrounded with its proper wall, besides a common one which inclosed the whole. The first of these cities was built by Seleucus Nicator, as already mentioned; the second by those who flocked thither on its being made the capital of the Syro-Macedonian empire; the third by Seleucus Callinicus; and the fourth by Antiochus Epiphanes. About four or five miles distant stood a place called Daphne, which was nevertheless reckoned a suburb of Antioch. Here Seleucus planted a grove, and in the middle of it built a temple, which he consecrated to Apollo and Diana, making the whole an asylum. To this place the inhabitants of Antioch resorted to indulge in amusements and impure pleasures, by which it became at last so infamous, that "to live after the manner of Daphne" was used as a proverb to express the most voluptuous and dissolute life.

Though Antioch continued to be, as Pliny calls it, the queen of the East, for near 600 years, yet scarcely any city mentioned in history has undergone such calamities, both from the attacks of its enemies, and the destructive shocks of earthquakes. The first disaster mentioned in history which befell the Antiochians happened about 145 years before Christ. Being at that time very much disaffected to the person and government of Demetrius their king, they were continually raising tumults and seditions. Wearied with their turbulence, he at last solicited assistance from the Jews, and was furnished by Jonathan, one of the Maccabees, with 3000 men. With this reinforcement believing himself sufficiently strong to reduce the mutineers by force, he ordered them immediately to deliver up their arms. This unexpected order caused a great uproar in the city. The inhabitants ran to arms and invested the king's palace, to the number of 120,000, with a design to put him to death. All the Jews hastened to his relief, fell upon the rebels, killed 100,000 of them, and set fire to the city. On the destruction of the Syrian empire by the Romans, Antioch submitted to them, and continued for a long time under

their dominion. About the year 115, in the reign of the Emperor Trajan, it was almost entirely ruined by one of the most dreadful earthquakes mentioned in history. Trajan himself happened to be there at the time, on his return from an expedition against the Parthians; so that the city was then full of troops and strangers from all quarters, either out of curiosity or upon business and embassies. The calamity was consequently felt in almost every province of the Roman empire. The earthquake was preceded by violent claps of thunder, unusual winds, and a dreadful noise under ground. Tho shock was so terrible, that great numbers of houses were overturned, and others rocked to and fro like a ship at sea. Those who happened to be in their houses were for the most part buried under their ruins; those who were walking in the streets or in the squares, were dashed to the ground by the violence of the shock, and most of them either killed or dangerously wounded. The earthquake continued, with small intermission, for several days and nights. Trajan was much hurt, but escaped through a window. Being an eyewitness of this terrible calamity, he would very probably contribute largely towards the re-establishment of Antioch in its ancient splendour. Its good fortune, however, did not continue long; for in 155 it was almost entirely destroyed by a fire, when it was again restored by Antoninus Pius.

When the Roman empire began to decline, Antioch became a source of contention between it and the Eastern nations; and accordingly, on the breaking out of a Persian war, it was almost always sure to suffer. In 242 it was taken and plundered by Sapor; and though he was defeated by Gordian, it underwent the same misfortune in the time of Valerian, about 18 years after; and subsequently to the defeat and captivity of Valerian, it was a third time taken by the Persian monarch, who not only plundered it, but levelled all the public buildings with the ground. The Persians, however, being soon driven out, this unfortunate city continued free from any remarkable calamity till about the time of the division of the Roman empire by Constantine in 331. It was then afflicted with so terrible a famine, that a bushel of wheat was sold for 400 pieces of silver. During this grievous distress, Constantine sent to the bishop 30,000 bushels of corn, besides an immense quantity of all kinds of provisions, to be distributed among the ecclesiastics, widows, orphans, &c. In the year 347 Constantius II. caused a harbour to be made at Seleucia, for the conveniency of Antioch. This was effected at great expense; the mouth of the Orontes, where the port was made, being full of sands and rocks. When the Emperor Julian set out on his expedition against the Persians, he made a long stay at Antioch, which then suffered severely from famine. In 381, in the reign of Theodosius the Great, Antioch was again visited by a famine, accompanied with a grievous plague. In 387 Theodosius, finding his exchequer quite drained, and being obliged to be at an extraordinary expense in celebrating the fifth year of the reign of his son Arcadius, and the tenth of his own, an extraordinary tax was laid upon all the people in the empire. Most of the cities submitted willingly to this; but the people of Antioch assailed their governor, broke some of the emperor's statues, and dragged others through the city, uttering the most injurious and abusive expressions against him and his whole family. They were dispersed by a body of archers, and the governor proceeded against the offenders with the utmost cruelty, exposing some to wild beasts in the theatre, and burning others alive. Many fled from the city and never returned. On hearing the news of the tumult, Theodosius was so much enraged that he commanded the city to be destroyed, and its inhabitants to be put to the sword without distinction; but this order was revoked before it could be put into execution, and he contented himself with inflicting severe punishments on individuals. In the year 458 Antioch was again almost entirely ruined by an earthquake, which happened on the 14th of September; scarcely a single house being left standing in the most beautiful quarter of the city. It experienced a similar misfortune in 526, during the reign of the Emperor Justin; and twelve years after, when taken by Chosroes king of Persia, that insulting and haughty monarch gave it up to his soldiers, who put all they met to the sword. The king himself seized on all the gold and silver vessels belonging to the great church, and caused all the valuable statues, pictures, &c., to be taken down and conveyed to Persia, while his soldiers carried off every thing else. The city being completely plundered, he ordered his men to set fire to it; and this was done so effectually, that none of the buildings even without the walls escaped. Such of the inhabitants as escaped slaughter were carried into Persia and sold as slaves. The city, however, was again restored, but in a short time underwent its usual fate, being almost entirely destroyed by an earthquake in 587, by which 30,000 persons lost their lives. In 634 it fell into the hands of the Saracens, who kept possession of it till the year 975, when it was surprised by one Burtzas, and again annexed to the Roman empire. The Romans continued masters of it for some time, till the civil dissensions in the empire gave the Turks an opportunity of mastering it, as well as the whole kingdom of Syria. From them it was again taken by the crusaders in 1098. In 1268 it was again taken by Bibaris, sultan of Egypt, who put a final period to its glory.

The ancient walls of Antioch are of surprising solidity; and are carried along the face of the precipitous hill on which the acropolis stood. They inclose a space of nearly seven miles in circumference, forming an irregular parallelogram. The modern city, according to Chesney, covers but a small part of the ancient Antioch, the remainder being occupied with mulberry groves, vineyards, and fruit gardens.

In 1835 it contained 5600 inhabitants, and 6000 Egyptian soldiers, when it was the headquarters of Ibrahim Pasha. It has never recovered the great earthquake of 1822.

Antioch, called by the Arabs *Antakiyah*, is now a ruinous town, whose houses, built with mud and straw, and narrow and miry streets, exhibit every appearance of misery and wretchedness. These houses are situated on the southern bank of the Orontes, at the extremity of an old decayed bridge: they are covered to the south by a mountain, upon the slope of which is a wall built by the crusaders. The distance between the present town and this mountain may be about 400 yards, which space is occupied by gardens and heaps of rubbish, but it presents nothing interesting. Antioch was better calculated than Aleppo to be the emporium of the Europeans. By clearing the mouth of the Orontes, which is six leagues lower down, boats might have been towed up that river, though they could not have sailed up, as Pococke has asserted, its current being too rapid. The natives, who never knew the name Orontes, call it, on account of the swiftness of its stream, *El Aasi*, that is, the rebel. Its breadth at Antioch is about forty paces. Seven leagues above that town it passes by a lake abounding in fish, and especially in eels. A great quantity of these are salted every year, but not sufficient for the numerous fasts of the Greek Christians. The plain of Antioch, though the soil of it is excellent, is uncultivated and abandoned to the Turkomans; but the hills on the side of the Orontes, particularly opposite Serkin, abound in plantations of figs and olives, vines and mulberry trees. Seleucus Nicator, who founded Antioch, built also at the mouth of the Orontes, on the northern bank, a large and well-fortified city, which bore his name, but of which at present not a single habitation remains; nothing is to be seen but heaps of rubbish,

and works in the adjacent rock, which prove that this was once a place of very considerable importance. In the sea also may be perceived the traces of two piers, which are indications of an ancient port, now choked up. The inhabitants of the country go thither to fish, and call the place *Souaidia*. Antioch is situated in Long. 37. 5. E. and Lat. 36. 20. N. (D. B—N.)

ANTIOCH, in *Pisidia*. The ruins of this city, of great magnificence, were discovered by Arundel, in 1833, about a mile from Yalobatch, and are in Lat. 38. 18. N. Long. 31. 23. E.—*Researches in Asia Minor.*

It was to this Antioch that Paul and Barnabas came on leaving Perga; and after preaching here, a commotion being raised against them by the Jewish inhabitants, "they shook off the dust of their feet." The city is said by Strabo to be in Phrygia, *near* Pisidia. The remains consist of an aqueduct, a theatre, foundations of temples, and innumerable fragments of fine cornices and columns.

ANTIOCH *ad Taurum*, now Aïntab; which see.

ANTIOCHIAN SECT or ACADEMY, a name given to what was called the fifth academy, from its being founded by Antiochus, a philosopher contemporary with Cicero. The Antiochian academy succeeded the Philonian. As to doctrine, the philosophers of this sect appear to have restored that of the ancient academy, except in the article of the criterion of truth. Antiochus was really a Stoic, and only nominally an Academic.

ANTIOCHIAN Epocha, a method of computing time from the proclamation of liberty granted to the city of Antioch about the time of the battle of Pharsalia.

ANTIOCHUS I., SOTER, king of Syria, was the son of Seleucus I., and began to reign in B.C. 280. He fell violently in love with his step-mother Stratonice, who was resigned to him by his father, on the discovery that this was the cause of the distemper which threatened his life. He was slain in battle against the Gauls in B.C. 261.

The most compact and unbroken account of the kings of this dynasty is to be found in Appian's book, *De Rebus Syriacis*, at the end. The dates of the following table are taken from Clinton's *Fasti Hellenici*, vol. iii. Appendix, ch. iii.:—

1. Seleucus Nicator, B.C. 312–280.
2. Antiochus Soter, his son, 280–261.
3. Antiochus Theus, his son, 261–247.
4. Seleucus Callinicus, his son, 247–226.
5. (Alexander, or) Seleucus Ceraunus, his son, 226–223.
6. Antiochus the Great, his brother, 223–187.
7. Seleucus Philopator, his son, 187–176.
8. Antiochus Epiphanes, his brother, 176–164.
9. Antiochus Eupator, his son (a minor), 164–162.
10. Demetrius Soter, son of Seleucus Philopator, 162–150.
11. Alexander Balas, *a usurper*, who pretended to be son of Antiochus Epiphanes, and was acknowledged by the Romans, 152–146. See ALEXANDER BALAS.

[12. Antiochus Theus, or Alexander (a minor), son of the preceding. He was murdered by the usurper Trypho, who contested the kingdom till 140.]

12. Demetrius Nicator, son of Demetrius Soter, reigned 146–141, when he was captured by the Parthians.
13. Antiochus Sidetes, his brother, 141–128.

Kings of the same family reigned in Antioch until Pompey reduced Syria to the form of a Roman province, B.C. 63.

ANTIOCHUS *of Ascalon*, a celebrated philosopher, the disciple of Philo of Larissa, the master of Cicero, and the friend of Lucullus and Brutus. He was founder of a fifth academy. See ANTIOCHIAN SECT.

ANTIOPE, in *Fabulous History*, the wife of Lycus, king of Thebes, who being deflowered by Zeus in the form of a Satyr, brought forth Amphion and Zethus. Another Antiope was queen of the Amazons, and, with the assistance of the Scythians, invaded the Athenians, and was vanquished by Theseus.

ANTIPÆDOBAPTISTS (derived from ἀντί, *against*, παῖς, παιδός, *child*, and βαπτίζω, *I baptize*), is a distinguishing denomination given to those who object to the baptism of infants. See BAPTISTS.

ANTIPAROS, an island in the Archipelago, opposite to Paros, from which it is separated by a strait about seven miles wide. It is the *Oleares* or *Oliaros* mentioned by Strabo, Pliny, Virgil, Ovid, &c.; and was, according to Heraclides Ponticus, as quoted by Stephanus, first peopled by a Phœnician colony from Sidon. According to Tournefort, it is about 16 miles in circumference.

This island is remarkable for a subterraneous cavern or grotto, accounted one of the greatest natural curiosities in the world. It is 300 fathoms below the surface of the earth, and appears to be about 40 fathoms high and 50 wide, penetrating far into the bosom of the island. It is full of large and beautiful stalactites. There have been many descriptions of this celebrated grotto, of which that by Tournefort is supposed to be very complete and exact.—*Relation d'un Voyage du Levant.*

ANTIPAS HEROD, or HEROD-ANTIPAS, the son of Herod the Great, by one of his wives called Malthake, a native of Jerusalem. Herod the Great, in his first will, appointed Antipas his successor in the kingdom; but afterwards altering that will, he named his son Archelaus his successor, giving to Antipas the title only of tetrarch of Galilee and Peræa.

Antipas took a great deal of pains in adorning and fortifying the principal places of his dominions. He married the daughter of Aretas, king of Arabia, whom he divorced about the year of Christ 33, to marry his sister-in-law Herodias, wife to his brother Philip, who was still living. John the Baptist was, by his orders, imprisoned in the castle of Machærus. Josephus attributes this imprisonment to Herod's fear lest John should make use of the authority which he had acquired over the minds of the people to induce them to revolt. But the evangelists, who, from their personal converse with John and his disciples, were better informed than Josephus, assure us that the true reason of imprisoning the Baptist was the aversion which Herod and Herodias had conceived against him for the liberty he had used in censuring their scandalous marriage. The virtue and holiness of John were such that even Herod feared and respected him; but his passion for Herodias would have induced him to kill that prophet, had he not been restrained by his apprehensions of the people, who esteemed John the Baptist as a prophet. (Matt. xiv. 5, 6.) One day, however, while the king was celebrating the festival of his birth with the principal persons of his court, the daughter of Herodias danced before him, and pleased him so well, that he promised with an oath to give her whatever she should ask of him. By her mother's advice she asked the head of John the Baptist; upon which the king commanded John to be beheaded in prison, and the head to be given her.

Aretas, king of Arabia, to revenge the affront which Herod had offered to his daughter, declared war against him, and overcame him in a very obstinate engagement. Herod being afterwards detected as a party in Sejanus's conspiracy, was banished by the Emperor Caligula to Lyons in Gaul, whither Herodias accompanied him. The time of his death is unknown.

ANTIPATER, regent of Macedonia during Alexander's eastern expedition. He gained this distinguished position by his faithful attachment and his prudence. In B.C. 330, he had to subdue the rebellious tribes of Thrace; but even before this insurrection was quelled, another broke out in Peloponnesus, where the Spartan king Agis rose against Macedonia. Having settled the affairs in Thrace as well as he could, Antipater hastened with an army to the south,

and in a battle near Megalopolis, gained a complete victory over the insurgents. He was much molested in his administration of Macedonia by the arrogance and ambition of Olympias, the mother of Alexander. The repeated complaints which both parties sent to Alexander, induced the latter to invite Antipater to Asia, and to appoint Craterus regent in his stead. But before this could be effected, Alexander died at Babylon. In the first division of the empire among the Macedonian generals, it was resolved that Antipater and Craterus should undertake the administration of the European parts of the empire, with the exception of Thrace, which was to be given to Lysimachus. The death of Alexander tempted the Greeks to assert their independence, but the prudence and valour of Antipater crushed all attempts in the Lamian war, and established the Macedonian rule in Greece on a firm footing. At the same time Craterus was engaged in a war against the Ætolians, when news arrived from Asia which induced Antipater to conclude peace with them; for Antigonus reported that Perdiccas was contemplating to make himself sole master of the whole empire. Antipater and Craterus accordingly prepared for war against Perdiccas, and allied themselves with Ptolemy, the governor of Egypt. Antipater crossed over into Asia, B.C. 321; and while still in Syria, he received information that Perdiccas had been murdered by his own soldiers. Antipater now, as administrator of the empire, made several new regulations, and having commissioned Antigonus to continue the war against Eumenes and the other partizans of Perdiccas, returned to Macedonia, where he arrived in B.C. 320. Soon after this he was seized by an illness which terminated his long and active life in B.C. 319. Passing over his son Cassander, he appointed Polysperchon regent, a measure which gave rise to much confusion and ill feeling. (L. S.)

ANTIPATER, an Idumean of illustrious birth, and possessed of great riches and abilities, taking advantage of the confusion into which the two brothers Hyrcanus and Aristobulus plunged Judæa by their contest for the office of high priest, took such measures as to gain for Hyrcanus that office, and under his government to obtain the absolute direction of all affairs. His great abilities raised him to such importance that he was honoured as much as if he had been formally invested with the royal authority. He was at last poisoned by a Jew named Malichus, B.C. 43. He left, among other children, the famous Herod, king of the Jews.

ANTIPATER, *Cœlius*, a Roman historian, who wrote a rhetorical history of the second Punic war, much valued by Cicero. The emperor Hadrian preferred him to Sallust.

ANTIPATER *of Sidon*, a Stoic philosopher, and likewise a poet, commended by Cicero and Seneca. He flourished about the 170th Olympiad. We have several of his epigrams in the *Greek Anthology*.

ANTIPATHY, in *Physiology*, is formed from the two Greek words, ἀντί, *contrary*, and πάθος, *passion*. Literally taken, the word signifies *incompatibility:* but for the most part the term *antipathy* is not used to signify such incompatibilities as are merely physical; it is reserved to express the aversion which an animated or sensitive being feels at the real or ideal presence of particular objects. In this point of view, which is the light in which we at present consider the term, *antipathy*, in common language, signifies a natural and involuntary aversion which a sensitive being feels for some other object, whatever it be, though the person who feels this abhorrence is entirely ignorant of its cause, and can by no means account for it. Such is, they say, the natural and reciprocal hostility between the toad and the weasel, between sheep and wolves. Such is the invincible aversion of particular persons against cats, mice, spiders, &c., a prepossession which is sometimes so violent as to make them faint at the sight of these animals. To

explore the matter without prejudice, we shall find it necessary to abstract from this disquisition all such antipathies as are not ascertained, as that which is supposed to be felt between the salamander and tortoise, and between the weasel and the toad. We must abstract those which can be extinguished or resumed at pleasure; those fictitious aversions which only certain persons feel or pretend to feel. When we abstract aversions, the causes of which are known and evident, we shall be surprised, after deduction of pretended antipathies, how small, how inconsiderable, is the quantity of those which are conformable to our definition. Will any one pretend to call by the name of *antipathy* those real, innate, and incontestable aversions which prevail between sheep and wolves? Their cause is obvious: the wolf devours the sheep, and subsists upon his victims; and every animal naturally flies with terror from pain or destruction: sheep ought therefore to regard wolves with horror, which, for their nutrition, tear and mangle the unresisting prey. From principles similar to this arises that aversion which numbers of people feel against serpents, against small animals, such as reptiles in general, and the greater number of insects. During the credulous and susceptible period of infancy, pains have been taken to impress on our minds the frightful idea that they are venomous; that their bite is mortal; that their sting is dangerous, productive of tormenting inflammations or tumours, and sometimes fatal: they have been represented to us as ugly and sordid; as being for that reason pernicious to those who touch them; as poisoning those who have the misfortune to swallow them. Is it then wonderful (if our false impressions as to this subject have been corrected neither by future reflections nor experiments) that we should entertain during our whole lives an aversion for these objects, even when we have forgot the admonitions, the conversations, and examples, which have taught us to believe and apprehend them as noxious beings? To explain these facts, is it necessary to fly to the exploded subterfuge of occult qualities inherent in bodies, to latent relations productive of antipathies, of which no person could ever form an idea?

To what then are those *antipathies* of which we have heard so much reducible? Either to legendary tales, or to aversions against objects which we believe dangerous, or to a childish terror of imaginary perils, or to a disrelish of which the cause is disguised, or to an infirmity of the stomach,—in a word, to a real or pretended dislike to things which are either invested or supposed to be invested with qualities hurtful to us. Too much care cannot be taken in preventing or regulating the *antipathies* of children; in familiarizing them with objects of every kind; in discovering to them, without emotion, such as are dangerous; and in teaching them the means of defence and security, or the methods of escaping their noxious influence.

ANTIPATHY, in *Ethics*, hatred, aversion, repugnancy. *Hatred* is entertained against persons, *aversion* and *antipathy* indiscriminately against persons or things, and *repugnancy* against actions alone.

ANTIPHILUS *of Egypt*, an eminent painter of antiquity, distinguished for the airy elegance of his style. He was the contemporary of Apelles, whose life he greatly endangered by falsely accusing him of treason before Ptolemy,—but his vile design being brought to light, Apelles was acquitted, and Antiphilus in turn was loaded with chains, and condemned to perpetual slavery.—(Plin. xxxv.; Lucian, *De Calumn.*, lix.)

ANTIPHLOGISTIC (from ἀντί and φλόγωσις, *inflammation*), is a term applied in medicine to the treatment of inflammation by the abstraction of blood, either local or general, the use of purgatives, nauseants, diaphoretics, refrigerants, &c., according to the exigencies of the case.

ANTIPHON, the most ancient of the ten Athenian orators contained in the Alexandrine canon. He was born in B.C. 480 at Rhamnus. During the Peloponnesian war he several times was entrusted with the command of detachments of the Athenian forces, and took an active part in the political affairs of Athens. He had a hand in the overthrow of the democracy, and the establishment of the oligarchy of the Four Hundred in B.C. 411; but as the new government was soon after changed, Antiphon was accused of high treason, and put to death. He must be regarded as the founder of political oratory at Athens, for he was the first that reduced the art of the orator to certain rules and principles. He wrote speeches for others, but never addressed the people himself except at his own trial. Seventeen orations have been preserved under his name, but two or three of them may be spurious. They are printed in the various collections of the Greek orators. From this Antiphon the orator we must distinguish two others; one a philosopher, mentioned by Xenophon (*Memor.* i. 6), who is said to have written about dreams, and the other, a tragic poet, who lived at the court of the elder Dionysius. (L. S.)

ANTIPHONARY, ANTIPHONARIUM, a service-book, which contained all the invitatories, responsories, collects, and whatever else was sung or said in the choir, except the lessons. This is otherwise called *responsorium*, from the responses contained therein. The author of the Roman *antiphonary* was Pope Gregory the Great. We also read of nocturnal and diurnal *antiphonaries*, for the use of the daily and nightly offices; summer and winter *antiphonaries;* also *antiphonaries* for country churches, &c. By the provincial constitutions of Archbishop Winchelsea, made at Merton A.D. 1305, it is required that one of these should be found in every church within the province of Canterbury. The use of these and many other popish books was forbidden by the 3d and 4th of Edward VI., c. 10.

ANTIPHONY, the answer made by one choir to another, when the psalm or answer is sung between two.

ANTIPHONY sometimes denotes a species of psalmody, wherein the congregation, being divided into two parts, repeat the psalms verse for verse alternately. In this sense antiphony stands contradistinguished from symphony, where the whole congregation sing together.

Antiphony differs from responsorium, because in this latter the verse is only spoken by one person, whereas in the former the verses are sung by two choirs alternately. The original of antiphonal singing in the Western churches is referred to the time of St Ambrose, about the year 374. That father is said to have first introduced it into the church of Milan, in imitation of the custom of the Eastern church, where it appears to be of greater antiquity, though as to the time of its institution authors are not agreed. It was probably introduced at Antioch between the years of Christ 347 and 356. Antiphony is also used to denote the words given out at the beginning of the psalm, to which both the choirs are to accommodate their singing. In a more modern sense it denotes a kind of composition made of several verses extracted out of different psalms, adapted to express the mystery solemnised on the occasion.

ANTIPODES, in *Geography*, a name given to those inhabitants of the globe that live diametrically opposite to each other. The word is Greek, and compounded of ἀντί, *opposite*, and πούς, *a foot*, because their feet are opposite to each other. Plato is regarded as the first who thought it possible that antipodes existed, and is looked upon as the inventor of the word. As this philosopher apprehended the earth to be spherical, he had only one step to make to conclude the existence of the antipodes. The ancients in general treated this opinion with the highest contempt, never being able to conceive how men and trees could subsist suspended in the air with their feet upwards, for so they apprehended they must be in the other hemisphere. They never reflected that these terms *upwards* and *downwards* are merely relative, and signify only nearer to, or farther from, the centre of the earth, the common centre to which all heavy bodies gravitate.

ANTIQUARII, a name given to copiers of old books. After the decline of learning among the Romans, and when many religious houses were erected, learning was chiefly in the hands of the clergy, the greater number of whom were regulars, and lived in monasteries. In these houses were many industrious men, who were continually employed in making new copies of old books, either for the use of the monastery or for their own emolument. These writing monks were distinguished by the name of *Antiquarii.*

ANTIQUARY, a person who studies and searches after monuments and remains of antiquity, as old medals, books, statues, sculptures, and inscriptions, and, in general, all curious pieces that may afford any insight into antiquity. In the chief cities of Greece and Italy there were persons of distinction called *antiquaries*, whose business it was to show strangers the antiquities of the place, to explain the ancient inscriptions, and to give them all the assistance they could in this kind of learning. Pausanias calls these antiquaries Ἐξηγηταί. The Sicilians called them *mystagogi.*

ANTIQUARY is also used by ancient writers for the keeper of the antiquarium or cabinet of antiquities. The officer is otherwise called *archæota*, or antiquary of a king, a prince, a state, or the like. Henry VIII. gave John Leland the title of his *antiquary.*

ANTIQUE, in a general sense, something that is ancient: but the term is chiefly used by sculptors, painters, and architects, to denote such pieces of their different arts as were made by the ancient Greeks and Romans. Thus we say, an antique bust, an antique statue, &c.

ANTIQUITIES. See ARCHÆOLOGY.

ANTIRRHINUM, snap-dragon, a genus of plants of the natural order of Scrofularinæ. The best known are the *A. majus*, and *A. orontium.*

ANTISABBATARIANS, a modern religious sect, who oppose the observance of the Christian sabbath. The great principle of the Antisabbatarians is, that the Jewish sabbath was only of ceremonial, not moral obligation, and consequently is abolished by the coming of Christ.

ANTISCII (ἀντί and σκία), those living on different sides of the equator, whose shadows at noon are projected opposite ways. Thus the people of the north are Antiscii to those of the south; the one projecting their shadows at noon towards the north pole, and the other towards the south.

ANTISEPTICS, from ἀντί, and σηπτός, *putrid*, of σήπω, *I putrefy*, an appellation given to such substances as resist putrefaction. We have some curious experiments in relation to antiseptic substances by Dr Pringle, who has ascertained their several virtues. Thus, in order to settle the antiseptic virtue of salts, he compared it with that of common sea-salt, which, being one of the weakest, he supposes equal to unity, and expresses the proportional strength of the rest by the higher numbers, as in the following table:—

Salts, their antiseptic virtue.

Sea salt	1	Saline mixture	3
Sal gemma	1 +	Nitre	4 +
Tartar vitriolated	2	Salt of hartshorn	4 +
Spiritus Mindereri	2	Salt of wormwood	4 +
Tartarus solubilis	2	Borax	12 +
Sal diureticus	2 +	Salt of amber	20 +
Crude sal ammoniac	3	Alum	30 +

In this table the proportions are marked in integral num-

bers; only to some there is added the sign +, to show that those salts are possessed of a stronger antiseptic virtue than the number in the table expresses, by some fractions; unless in the three last, where the same sign imports that the salt may be stronger by some units. To these add kreasote, alcohol, and various metallic salts.

ANTISPASMODICS are medicines proper for the cure of spasms and convulsions. Opium, ammonia, musk, and the essential oils of many vegetables, are the principal in this class of medicines.

ANTISTASIS, in *Oratory*, a defence of an action from the consideration that, had it been omitted, worse would have ensued. This is called by Latin writers *comparativum argumentum;* such, *e. g.*, would be the general's defence who had made an inglorious capitulation, that, without it, the whole army must have perished.

ANTISTHENES, a Greek philosopher, and founder of the sect of the Cynics, who flourished about 380 B.C. He was born at Athens, and passed the early part of his life as a soldier. He was first a pupil of the sophist Gorgias, but afterwards became a zealous disciple and friend of Socrates, whom he faithfully attended till his death. The exhortations of his master to temperance and simplicity of life were carried by him into practice with a strictness bordering on fanaticism. Permitting his beard to grow, he went about the streets in a thread-bare coat, scarcely to be distinguished from a common beggar; an affectation of severity that called forth the satirical remark of Socrates, "that the pride of Antisthenes peeped out through the holes of his cloak." He prided himself upon the most rigid virtue, and thought it his duty to attack the vicious wherever he found them. This gave him some reputation in the city; but it may be supposed that, in the luxurious city of Athens, he had more enemies than disciples. His philosophy was exclusively practical; despising speculative science, he held the nature of things to be undefinable, and all opinions to be identical. Virtue, which he held to be the supreme good, consisted, with him, in temperance, and freedom from the dominion of the passions, by means of which the wise man becomes independent of all external circumstances, and possesses in himself all the sources of felicity and perfection. Virtue is the only beauty; vice the only deformity; all things else are indifferent (ἀδιάφορα) and unworthy of pursuit. Regarding the Deity, as Cicero (*De Nat. Deor.* i. 13) informs us, he held "that the gods of the people were many, but that the true God was One." Notwithstanding the repulsive austerity of his manners, the elevated ethical teaching of Antisthenes drew around him a numerous body of disciples (see CYNICS), of whom the most celebrated was Diogenes of Sinope; and by his twofold influence, positive and negative, he may be regarded as the parent of Stoicism on the one hand, and of Pyrrhonism on the other.

The works of Antisthenes formed, according to Diogenes Laërtius, ten books; of these there are now extant only two discourses entitled *Ajax* and *Ulysses;* and some letters. The collected fragments were published by Winckelmann. Turici, 1842.

ANTISTROPHE, among *Lyric Poets*, that part of a song and dance, in use among the ancients, which was performed before the altar, in returning from west to east: in opposition to strophe.

ANTITACTÆ, in *Ecclesiastical History*, a sect of Gnostics, who held that not God but a creature had created evil; and consequently that it is our duty to oppose ourselves to (ἀντιτάσσεσθαι) this enemy of God.

ANTITHESIS, in *Rhetoric*, a contrast or opposition of words or sentiments. Such is that of Cicero, in the second Catilinarian: "On one side stands modesty, on the other impudence; on one fidelity, on the other deceit; here piety, there sacrilege; here continency, there lust." A judicious use of this figure imparts much force and spirit to style; but its ostentatious recurrence becomes tedious. The poetry of Pope may be cited as an example.

ANTITRINITARIANS, those who deny the Trinity, and teach that there are not three persons in the Godhead. Thus the Samosatenians, who do not believe the distinction of persons in God; the Arians, who deny the divinity of the Word; and the Macedonians, who deny that of the Holy Spirit, are all properly Antitrinitarians. Among the moderns, the term is particularly applied to Socinians, called also Unitarians.

The *Bibliotheca Antitrinitariorum* is a posthumous work of Christopher Sandius, an eminent Antitrinitarian, in which he gives a chronological list of all the Socinian or modern Antitrinitarian authors, with a brief account of their lives, and a catalogue of their works.

ANTITYPE, a Greek word, properly signifying a type or figure corresponding to some other type. The word occurs twice in the New Testament, viz., in the Epistle to the Hebrews, ix. 24, and in St Peter's 1st Ep. iii. 21, where its genuine import has been much controverted. The former says that "Christ is not entered into the holy places made with hands, which are, ἀντίτυπα, the figures or antitypes of the true—now to appear in the presence of God for us." Now τύπος signifies the pattern by which another thing is made; and as Moses was obliged to make the tabernacle, and all things in it, according to the pattern shown him in the mount, the tabernacle so formed was the antitype of what was shown to Moses: anything, therefore, formed according to a model or pattern is an antitype.

ANTITYPE, among the *Ancient Greek Fathers*, and in the Greek liturgy, is also applied to the symbols of bread and wine in the sacrament. Hence it has been argued by many Protestants, that the Greeks do not really believe the doctrine of transubstantiation, because they call the bread and wine *antitypes*, ἀντίτυπα, q. d., *figures*, *similitudes*, and this even after the consecration.

ANTIUM, a celebrated city of the Volsci, on the coast of Latium, now *Porto d'Anzo.* It was the refuge of Coriolanus, and afterwards became a Roman colony. In the time of Cicero it was a favourite retreat of the wealthy citizens. The extent of the ruins shows its importance in ancient times. It is thirty-two miles south-east of Rome.

ANTIVARI, or BAR, a strongly-fortified frontier town and harbour in the Gulf of Venice, in the Turkish pachalic of Iscander or Scutari. It is the seat of a Catholic bishop, and contains 6000 inhabitants, many of whom own vessels, which are hired for the coasting trade of the Adriatic. Lat. 42. 2. N. Long. 19. 10. E.

ANTLIA, an ancient machine, supposed to be the same with our pump. Hence the phrase *in antliam condemnari*, according to the critics, denotes a kind of punishment whereby criminals were condemned to drain ponds, ditches, or the like. But prior to the invention of the pump this word was applied indifferently to any implement for drawing water; and even so late as the time of St John ἄντλημα is used to signify merely *a bucket with a rope.* John. iv. 11.

ANTLIA, in *Entomology*, the oral instrument of lepidopterous insects, used for suction.

ANTŒCI (ἀντί and οἰκέω), those who live under the same meridian, and at the same distance from the equator; the one toward the north, and the other toward the south. Hence they have the same longitude; and their latitude is also the same, but of a different denomination: they are in the same semicircle of the meridian, but in opposite parallels: they have precisely the same hours of the day and night, but opposite seasons; and the night of the one is always equal to the day of the other.

ANTOINE, St, a town of France, in the department of Isere, with a celebrated abbey. It is seated among the mountains, eight miles W.N.W. of St Marcellin. Pop. 2007.

ANTONELLO *Da Messina*, the first Italian painter who used *oil colours*. Having seen, in the palace of Alfonso I. of Naples, a picture of Jan Van Eyck in this style, he set out for Flanders, and obtained the secret from the painter of Bruges, with whom he remained until the death of Van Eyck in 1445. After that he returned to Messina for a time; but in 1450 set out for Venice, where he communicated the important Flemish secret to Domenico Veneziano. He then paid a long visit to Milan; but finally returned to Venice, where he died in 1493. He seems to have freely communicated the modes of painting in oil, especially in this latter period of his life, and had a salary from the state. He had a high reputation, and was the most illustrious artist in the first epoch of the Neapolitan school.—See *Ridolfi Vite de Pittori*, *Zanetti Pint. Venez.*, and *Lanzi Storia Pittorica*, tom. ii. (T. S. T.)

ANTONIA, a fortress in Jerusalem, on the north side of the area of the temple, originally built by the Maccabees, under the name of Baris, and afterwards rebuilt with great strength and splendour by the first Herod. Josephus states that the fortress stood upon a rock or hill fifty cubits high, at the north-west corner of the temple area, above which its walls rose to the height of forty cubits. Within, it had the extent and appearance of a palace, being divided into apartments of every kind, with galleries and baths, and broad halls or barracks for soldiers; so that, having everything necessary within itself, it seemed a city, while in magnificence it resembled a palace. The fortress communicated with the northern and western porticoes of the temple area, and had flights of stairs descending into both, by which the garrison could at any time enter the courts of the temple, and prevent tumults. This is the "castle" into which Paul was carried from the temple by the soldiers: and from the stairs of which he addressed the people collected in the adjacent court (Acts xxi. 31–40).

ANTONIAN Waters, medicinal waters of Germany, very pleasant to the taste, and esteemed in many chronic and hypochondriac cases.

ANTONIANO, Silvio, a man of great learning, who raised himself from a low condition by his merit, was born at Rome in the year 1540. At the age of ten he could make verses impromptu on any subject proposed. The duke of Ferrara, coming to Rome to congratulate Marcellus II. on his elevation to the pontificate, was so charmed with the genius of Antoniano, that he carried him to Ferrara, where he made him professor of literature at the age of sixteen. From thence he was sent for by Pius IV., who made him professor of the belles lettres in the college of Wisdom at Rome. Antoniano filled this place with so much reputation, that, on the day when he began to explain the oration of Cicero *pro Marcello*, he had among his numerous auditors no less than twenty-five cardinals. He was afterwards chosen rector of the college; and after the death of Pius IV., being seized with a spirit of devotion, he joined himself to Filippo Neri, and accepted the office of secretary to the sacred college, offered him by Pius V., which he held for twenty-five years. He refused three bishoprics which Gregory XIV. would have given him; but he accepted the office of secretary to the Briefs, offered him by Clement VIII., who made him his chamberlain, and afterwards a cardinal. His excessive application to study brought on a sickness, of which he died in the sixty-third year of his age. A work of his on education was published at Verona in 1584, 4to; and some *Orations* appeared after his death in 1610, 4to, Rome. He wrote, besides, numerous discourses and poems, both in Latin and Italian.

ANTONIDES, Hans, surnamed Vander Goes, an eminent Dutch poet, was born at Goes in Zealand on the 3d of April 1647. His parents were Anabaptists, people of good character, but in poor circumstances. They went to live at Amsterdam when Antonides was about four years old; and in the ninth year of his age he began his studies, under the direction of Hadrian Junius and James Cocceius. The study of the Latin poets first awakened his poetic spirit. His earliest attempts were translations from Horace and Ovid; and, having formed his taste on these excellent models, he at length ventured to write a tragedy, entitled, *Trazet, or the Invasion of China;* which, however, his modesty prevented him from publishing.

His parents designed him for an apothecary; but his remarkable genius for poetry soon gained him the esteem and friendship of several persons of distinction, and particularly of Buisero, one of the lords of the admiralty at Amsterdam, who sent him at his expense to pursue his studies at Leyden. There he took his degree of doctor of physic, after which his patron gave him a place in the admiralty. He died on the 18th September 1684, at the early age of 37. A complete edition of his works, with a life of the poet, was printed at Amsterdam, 4to, 1714. The most esteemed of his poems, which are characterised by warmth and vigour, is his epic on the river Y, entitled *Y-stroom.*

ANTONIN, St, a town of France, department of Tarn and Garonne, in a valley at the confluence of the rivers Aveyron and Bonnette, 22 miles north-east of Montauban. It is the capital of a canton, and has 2691 inhabitants. The manufactures are linen, leather, woollens, &c.

ANTONINI Itinerarium. See Itinerary.

ANTONINUS Liberalis, a Greek grammarian, who probably lived about A.D. 147. His work on metamorphoses is chiefly valuable for the study of Greek mythology. One of the best editions is that of Koch, Leipz. 1832, 8vo.

Antoninus, *Marcus Aurelius*, surnamed the *Philosopher*, a very eminent Roman emperor, born at Rome on the 20th of April, A.D. 121. He was called by several names till he was admitted into the Aurelian family, when he took that of Marcus Aurelius Antoninus. Hadrian, upon the death of Ceionius Commodus, turned his eyes upon Marcus Aurelius; but, as he was not then 18 years of age, and consequently too young for so important a station, he fixed upon Antoninus Pius, whom he adopted, upon condition that he should likewise adopt Marcus Aurelius. The year after this adoption, Hadrian appointed him questor, though he had not yet attained the age prescribed by law. After the death of Hadrian, Aurelius married Faustina, the daughter of Antoninus Pius, by whom he had several children. In the year 139 he was invested with new honours by the Emperor Pius, which he bore in such a manner as endeared him to that prince and the whole people.

On the death of Pius, in the year 161, he was invested by the senate with the imperial power, taking as his colleague L. Ceionius Commodus, thenceforward called L. Aurelius Verus. Dion Cassius says that he was induced to this by his ill health, and the desire of leisure to pursue his studies; Lucius being of a strong, vigorous constitution, and consequently more fit for the fatigues of war. The same day he assumed the name of Antoninus, which he bestowed likewise on his colleague Verus, to whom, at the same time, he betrothed his daughter Lucilla.

The happiness which the empire began to enjoy under the two emperors was soon interrupted. In the year 162, a dreadful inundation of the Tiber destroyed a vast number of cattle, and occasioned a famine at Rome. This calamity was followed by the Parthian war; and at the same time the Catti ravaged Germany and Rhætia. Lucius Verus went in person to oppose the Parthians; and Antoninus remained

at Rome, where his presence was necessary. Less through the ability of Verus than the conduct of his lieutenant, the war with the Parthians was successfully terminated. The two emperors shared the honours of a magnificent triumph at Rome in the year 166, and were honoured with the title of *Fathers of their country*. In this year the city was ravaged by famine and by a terrible pestilence which spread itself over the whole world. It was likewise in this year that the Marcomanni, and many other people of Germany, took up arms against the Romans; but the two emperors, having marched in person against them, obliged them to sue for peace. The war, however, was renewed the year following, and the two emperors again opened the campaign in person. Lucius Verus was seized with an apoplectic fit, and died at Altinum. The whole conduct of the war now devolved on his successor, who found his resources so straitened, that to save the people from new taxes, he parted with the plate and furniture of his palace, and even with the empress's jewels, in order to meet the demands of the war. His self-denying and vigorous exertions were crowned with the greatest success.

During this war, in 174, a very extraordinary event is said to have happened, which, according to Dion Cassius, was as follows: Antoninus's army being blocked up by the Quadi in a very disadvantageous place, where there was no possibility of procuring water, and being worn out with fatigue and wounds, oppressed with heat and thirst, and incapable of retiring or engaging the enemy, in an instant the sky was covered with clouds, and there fell a vast quantity of rain. The Roman army were about to quench their thirst when the enemy came upon them with such fury, that they must certainly have been defeated, had it not been for a shower of hail, accompanied with a storm of thunder and lightning, which fell upon the enemy without the least annoyance to the Romans, who by this means gained the victory.[1] In 175 Antoninus made a treaty with several nations of Germany. Soon after, Avidius Cassius, governor of Syria, urged on by Faustina, revolted from the emperor. This insurrection, however, soon ended in the murder of Cassius by his own partisans. Antoninus behaved with great lenity towards those who had been engaged in Cassius's party: he would not put to death, nor imprison, nor even sit in judgment himself upon any of the senators engaged in this revolt; but he referred them to the senate, fixing a day for their appearance, as if it had been only a civil affair. He wrote also to the senate, desiring them to act with indulgence rather than severity; nor to shed the blood of any senator or person of quality, or of any other person whatever; but to allow this honour to his reign, that, even under the misfortune of a rebellion, none had lost their lives except in the first heat of the tumult. In 176 Antoninus visited Syria and Egypt. The kings of those countries, and ambassadors also from Parthia, came to visit him. He staid several days at Smyrna; and, after settling the affairs of the East, went to Athens; on which city he conferred several honours, and appointed public professors there. From thence he returned to Rome with his son Commodus, whom he chose consul for the year following, though he was then but 16 years of age, having obtained a dispensation for that purpose. On the 27th of September in the same year he gave him the title of *Imperator;* and on the 23d of December he entered Rome in triumph with Commodus, on account of the victories gained over the Germans. Dion Cassius tells us that he remitted all the debts which were due to himself and the public treasury during 46 years, and burnt the writings relating to these debts. In the year 177 he left Rome with his son Commodus, to march against the Marcomanni and other barbarous nations. In the following year he gained a considerable victory over them, and would in all probability have entirely subdued them, had he not been seized with an illness, which carried him off on the 17th of March 180, in the 59th year of his age, and 20th of his reign. The character of this prince affords the highest instance of what the Stoical philosophy could do in moulding a disposition naturally tranquil and benevolent. Alike in his public and private life, Antoninus moved like a superior being among the rest of mankind. Master of himself, and ever influenced by the highest motives which heathen morality could suggest, he was deeply and universally beloved; and a people who believed in the divine descent of Romulus and his bodily return to heaven, might well celebrate with more than empty ceremony the apotheosis of Antoninus, and reverently set up his statue in their houses. But his persecution of the Christians, to which, doubtless, he was instigated by evil counsellors, is an indelible stain on a character otherwise so estimable. The martyrdom of Justin at Rome, of the venerable Polycarp, with many others at Smyrna, took place about the 7th year of his reign; and that he sanctioned the horrible atrocities perpetrated at Vienna and Lyons ten years later, is confirmed by the answer returned to the Roman governor, who applied for instructions, that all who professed Christianity should be put to death. The only work of his that remains, besides some letters in the remains of Fronto, discovered by Mai at Rome, is his book of Meditations, originally written in Greek (τῶν ἐις ἑαυτὸν βιβλία δώδεκα). It consists of miscellaneous reflections on moral and religious subjects, expressive of the thoughts and feelings of the writer, in the midst of the daily business of life, the manifold cares and routine of a court, or the distracting tumult of the camp. Together with the writings of Epictetus, these form the most valuable remains of the Stoical school, and faithfully describe the mode of self-discipline by which its higher representatives formed their minds in the habit of virtue. The best edition is that of Gataker, Cantab. 1652, reprinted, London, 1697, with Dacier's notes and life of Antoninus, translated into Latin by Stanhope. It has been frequently translated. The best English version is that by Drs Moor and Hutcheson, 2 vols. 12mo, 1749.

Eusebius, *E. H.* iv. 16.

Antoninus, *Titus Aurelius Fulvus Boionius Arrius*, surnamed *Pius*, emperor of Rome, was born A.D. 86, at Lanuvium in Italy. The family of his father, from whom he inherited great wealth, was originally from Nismes in Gaul. Both his father and grandfather had held the office of consul. Arrius Antoninus, his maternal grandfather, by his amiable disposition and love of literature, had acquired an eminent character, and was very intimate with Pliny the younger. Under him the young Titus, after his father's death, completed his education. His character, on arriving at the age of maturity, manifested itself in the most promising manner. To an outward mien at once mild and dignified, he joined a cultivated understanding, a virtuous heart, and a manly eloquence. Simple in his tastes, and

[1] The Pagans, as well as Christians, according to M. Tillemont (art. xvi. p. 621), have acknowledged the truth of this prodigy, but have greatly differed as to the cause of such a miraculous event, the former ascribing it, some to one magician and some to another. In Antoninus's pillar the glory is ascribed to Jupiter, the god of rain and thunder. But the Christians affirmed that God granted this favour at the prayer of the Christian soldiers in the Roman army, who are said to have composed the twelfth or Melitene legion; in consequence of which they received the title of the *Thundering Legion.* (Euseb. *Eccles. Hist.* lib. v. cap. 5.) Mr Moyle, in the letters published in the second volume of his works, has endeavoured to explode this story of the Thundering Legion, to which Mr Whiston published an answer in 1726. More recently the subject has been extensively argued on both sides, with an ingenuity scarcely demanded by its importance.

Antoninus. guided by temperance in all his sentiments and actions, he was entirely free from the usual vices of imperial rank.

In the year 120, among the many public honours which his birth and connections gave him a claim to, he was elevated to the high post of consul, and was afterwards appointed by Hadrian to be one of the four consulars among whom the supreme power of Italy was divided. Becoming in his turn proconsul of Asia, he acquitted himself with such reputation that he even excelled his grandfather Arrius, who had formerly enjoyed that high trust. Returning from Asia, he was received into the favour and confidence of Hadrian. He married Annia Faustina, the daughter of Annius Verus, whose character was far from being irreproachable; but his lenient disposition induced him to avoid public scandal, and he behaved towards his aged father-in-law with the most becoming respect. Two sons and two daughters were the fruits of this marriage. The sons died young, and the eldest daughter, who was married to Lamia Syllanus, died, when Titus proceeded towards his Asiatic government. Faustina, the youngest, married Marcus Aurelius, who was afterwards emperor.

After the death of Verus, Hadrian adopted Antoninus as his successor in the Roman empire, with the title of Cæsar, A.D. 138; and at the same time created him his colleague in the proconsular and tribunitian offices. Extending his plans of adoption still farther, he caused Antoninus to adopt the son of Verus, then seven years of age, and Marcus Annius, afterwards named Aurelius, then seventeen years of age, a relation of Hadrian's, and nephew to his own wife. The dutiful and merited attention which Antoninus bestowed on Hadrian during the last months of his illness, justifies, in conjunction with his general character, the epithet afterwards bestowed upon him. On July 10, A.D. 138, he succeeded to the empire amidst the universal acclamations of the senate and people, who anticipated in his well-tried virtues that happiness which a good and wise sovereign is able to bestow upon his subjects.

The Roman world enjoyed such tranquillity under his reign that it affords few materials for history; yet it is to be regretted that Capitolinus is the only historian from whom any direct information can be received concerning this peaceful period, and he is none of the most perspicuous. It however appears that the usual honours and titles, together with the addition of the surname of Pius, which the general tenor of his life and his zeal in defending and honouring the memory of his predecessor united to suggest, were willingly conferred upon him by the senate. In the beginning of his reign there were several conspiracies formed against him; but these only afforded him opportunities of signalizing his singular clemency. Though unable to prevent the course of justice against the ringleaders, he prohibited the prosecution of their accomplices, and took the son of Attilius, one of the principal conspirators, under his protection. Various commotions were raised in several parts of the empire; but by the vigilance of his lieutenants these were easily quelled. The incursions of the Brigantes in Britain were restrained, and a new wall which was built to the north of that of Hadrian, extending from the Forth to the Clyde, and which was called the *Wall of Antoninus*, was fixed as the boundary of the Roman province in Britain. The reign of Antoninus, upon the whole, was singularly peaceful, and realised a saying of Scipio, that "he preferred saving the life of one citizen, to destroying a thousand enemies."

Jurisprudence was to this emperor, as it was to his predecessor, an interesting subject for improvement; and several decrees which he issued display his commendable spirit of equity. The natural consequence of this equity was, that Antoninus acquired a reputation and fame which no military achievements could have conferred; and his friendship was courted by the neighbouring princes.

There is scarcely a blot to be found to tarnish his character; and frugality, modesty, and harmless amusement continued to employ his private hours. In the management of his complicated business he was exact to such a degree, that it was even ridiculed by some; but he found the daily advantage of this accuracy. The growing virtue of Marcus Aurelius soon drew his attention after he ascended the throne, and having given him his daughter in marriage, he declared him Cæsar. Nor was he mistaken in his choice; for Aurelius acted with the utmost fidelity and affection amid all the honours that he continued to confer upon him. But his prosperous reign was drawing to a close: in the 75th year of his life he was seized with a fever at his favourite country-seat of Lorium. Assured of his approaching death, he convened the principal officers of the state, confirmed his election of Aurelius, and gave him the imperial ensigns. A delirium ensued, in an interval of which the tribune of the night-watch having came, as was customary, to receive the pass-word, the dying emperor uttered the stoical watchword *Æquanimitas*, and calmly resigned his breath in the 23d year of his reign. His ashes were consigned to the tomb of Hadrian, and divine honours paid to his memory. He was universally regretted, and succeeding emperors for more than a century bore his name as a title of honour. The senate and his successor erected a sculptured pillar to his memory, which still exists as one of the chief ornaments of the city of Rome.

Antoninus's Wall. ANTONINUS'S WALL, the name of the third rampart or defence that had been built or repaired by the Romans against the incursions of the North Britons. It is called by the people in the neighbourhood *Graham's Dike*, from the opinion that one Graham, or Grimus, first made a breach in it after the retreat of the Romans out of Britain. The first barrier erected by the Romans was the chain of forts made by Agricola from the firth of Forth to that of Clyde, in the year 81, to protect his conquest from the inroads of the Caledonians. The second was the vallum or dike thrown up by Hadrian in the year 121. It terminated on the western side of the kingdom at *Axelodunum* or *Brugh*, on the Solway sands, and at *Pons Ælii* or *Newcastle* on the eastern. The rampart of Hadrian was situated much farther south than Agricola's chain; the country to the north having been either recovered, according to some authors, by the native Britons after the departure of Agricola, or, according to others, voluntarily slighted by Hadrian. However, this work of Hadrian's did not long continue to be the extreme boundary of the Roman territories to the north in Britain; for Antoninus Pius, the adopted son and immediate successor of Hadrian, having, by his lieutenant Lollius Urbicus, recovered the country once conquered by Agricola, commanded another rampart to be erected between the firths of Forth and Clyde, in the track where Agricola had formerly built his chain of forts. The great number of inscriptions which have been found in or near the ruins of this wall or rampart, to the honour of Antoninus Pius, leave us no room to doubt its having been built by his direction and command. If the fragment of a Roman pillar with an inscription, now in the college library of Edinburgh, belonged to this work, as is generally supposed, it fixes the date of its execution in the third consulship of Antoninus, which was A.D. 140, only twenty years after that of Hadrian, of which this seems to have been an imitation. This wall or rampart, as some imagine, reached from Carriden on the firth of Forth to Old Kirkpatrick on the Clyde; or, as others think, from Kinniel on the east to Dunglass on the west. These different suppositions hardly make a mile of difference in the length of this work, which, from several actual mensurations, appears to have been 37 English or 40 Roman miles. Capitolinus, in his life of Antoninus Pius, directly affirms that

the wall which that emperor built in Britain was of turf. This in the main is unquestionably true, though it is evident (from the vestiges of it still remaining, which not very many years ago were dug up and examined for near a mile together) that the foundation was of stone. Mr Camden also tells us that the principal rampart was faced with square stone, to prevent the earth from falling into the ditch. The chief parts of this work were as follows: 1. A broad and deep ditch, whose dimensions cannot now be discovered with certainty and exactness, though Mr Pont says it was 12 feet wide. 2. The principal wall or rampart was about 12 feet thick at the foundation, but its original height cannot now be determined. This wall was situated on the south brink of the ditch. 3. A military way on the south side of the principal wall, well paved, and raised a little above the level of the ground. This work, as well as that of Hadrian, was defended by garrisons placed in forts and stations along the line of it. The number of these forts or stations, whose vestiges were visible in Mr Pont's time, was 18, situated at about the distance of two miles from each other. In the intervals between the forts there were turrets or watch-towers; but the number of these, and their distance from each other, cannot now be discovered.

It is not a little surprising, that though it is now more than 1700 years since this work was finished, and more than 1400 since it was neglected, we can yet discover, from authentic monuments which are still remaining, by what particular bodies of Roman troops almost every part of it was executed. This discovery is made from inscriptions upon stones, which were originally built into the face of the wall, and have been found in or near its ruins. From these inscriptions it appears in general, that this great work was executed by the second legion, the vexillations of the sixth legion and of the twentieth legion, and one cohort of auxiliaries. Some of these inscriptions have suffered greatly by the injuries of time and other accidents; so that we cannot discover from them with absolute certainty how many paces of this work were executed by each of these bodies of troops. The sum of the certain and probable information contained in these inscriptions, as it is collected by Mr Horsley, stands thus:

	Paces.
The second legion built	11,603
The vexillation of the twentieth legion	7,411
The vexillation of the sixth legion	7,801
All certain	26,815
The vexillation of the twentieth legion, the monument certain, and the number probable	3,411
The same vexillation on a plain monument, no number visible, supposed	3,500
The sixth legion, a monument, but no number, supposed	3,000
Cohors prima Cugernorum	3,000
Total	39,726

or 39 Roman miles 726 paces, nearly the length of the wall. It would be both useful and agreeable to know how long these troops were employed in the execution of this great work. But of this we have no information. Neither do we know what particular bodies of troops were in garrison in the several forts and stations along the line of this wall, because these garrisons were withdrawn before the *Notitia Imperii* was written.—See *Gordon's Itinerarium Septentrionale, and Maitland's History of Scotland.*

Though we cannot discover exactly how many years this wall of the Emperor Antoninus continued to be the boundary of the Roman territories in Britain, yet we know with certainty that it was not very long. For we are told by an author of undoubted credit (Dion Cassius, lib. lxxii.), that, in the reign of Commodus, A.D. 180, "he had wars with several foreign nations, but none so dangerous as that of Britain; for the people of the island having passed the wall which divided them from the Romans, attacked them, and cut them to pieces."

ANTONIO, Nicholas, knight of the order of St James, and canon of Seville, was born at Seville in 1617, being the son of a gentleman whom King Philip IV. made president of the admiralty established in that city in 1626. After having gone through a course of philosophy and divinity in his own country, he studied law at Salamanca. Upon his return to Seville, he shut himself up in the royal monastery of Benedictines, where he employed himself several years in writing his *Bibliotheca Hispanica,* having the use of the books of Bennet de la Sana, abbot of that monastery, and dean of the faculty of divinity at Salamanca. By this help, and about 30,000 volumes in his own library, joined to continual labour and indefatigable application, he was at last enabled to finish his *Bibliotheca Hispanica,* in four volumes folio, two of which he published at Rome in the year 1672. The work consists of two parts; the one containing the Spanish writers who flourished before the fifteenth century, and the other those since the end of that century. After the publication of these two volumes, he was recalled to Madrid by King Charles II. At his death, which took place in 1684, he left nothing but his vast library; and his two brothers and nephews being unable to publish the remaining volumes of his *Bibliotheca,* sent them to Cardinal d'Aguisine, who paid the expense of the impression, and committed the superintendence of it to M. Martin, his librarian, who added notes in the name of the cardinal. These two volumes were published in 1696. Improved editions of both these works, by F. P. Bayer, were published at Madrid in 4 vols. folio, in 1783–8. A work by Antonio was published for the first time at Valencia in 1742, entitled *Censura de Historias Fabulas, obra postuma,* folio.

ANTONIUS, Marcus, a famous Roman orator. While he filled the office of prætor, Sicily fell to his lot, and he cleared the seas of the pirates which infested that coast. He was made consul with A. Postumius Albinus, in the year B.C. 99, when he opposed the turbulent designs of Sextus Titus, tribune of the people, with great resolution and success. Some time after he was made governor of Cilicia, in quality of proconsul, where he performed so many great exploits that he obtained the honour of a triumph. He was one of the greatest orators ever known at Rome; and it was owing to him, according to the testimony of Cicero, that Rome might boast herself a rival even to Greece itself in the art of eloquence. He never would publish any of his pleadings, that he might not, as he said, be proved to say in one cause what might be contrary to what he should advance in another. He was killed, B.C. 87, during those bloody confusions raised at Rome by Marius and Cinna. His hiding-place being discovered, soldiers were sent to despatch him; but the power of his eloquence so moved them, that none but he who commanded them, and had not heard his discourse, had the cruelty to kill him. His head was exposed before the rostra, a place which he had adorned with his triumphal spoils.

Antonius, *Marcus,* the triumvir, was born about the year B.C. 83. He was grandson to M. Antonius the orator, and the son of that M. Antonius who was surnamed in derision *Creticus,* from the place where he died, after plundering the provinces he was appointed to defend. Antonius being very young when his father died, he was brought up by Cornelius Lentulus, who married his mother Julia, and was afterwards put to death by Cicero as one of Catiline's conspirators; an act afterwards fatally revenged by Antony, whose hatred for Cicero was sharpened by his philippics against himself. After involving his affairs deeply by dissipation and extravagance, in his twenty-fifth year he joined the army in Syria,

where he served with distinction under A. Gabinius; and during the three succeeding years he took part in the campaigns against Aristobulus in Palestine, and in the restoration of Ptolemy Auletes to the throne of Egypt. He served afterwards under Cæsar in Gaul; and when the civil war broke out, he took Cæsar's part, and was made a tribune of the people, in which office he did Cæsar great service. Cæsar, having made himself master of Rome, gave Antony the government of Italy. At the battle of Pharsalia Cæsar confided so much in him, that he gave him the command of the left wing of his army, while he himself led the right. After Cæsar was made dictator he made Antony general of the horse, though he had never been prætor; in which command he exerted his power with the utmost violence. He was made consul when Cæsar enjoyed that honour for the fifth time, the last year of that usurper's life. On Cæsar's death he harangued the populace with great art, and raised their fury against his murderers, flattering himself that he should easily get into the place which Cæsar had filled; but his haughty behaviour lost him all the advantages his affected concern for Cæsar had gained him. His ill-treatment of Octavius, and quarrel with him, produced another civil war, which ended in an accommodation between him, Octavius, and Lepidus, fatal to the peace of Rome. They agreed to share the supreme power among them; and many of the most illustrious Romans were sacrificed by proscription to cement this bloody league, which is known by the name of the *Second Triumvirate*. The year B.C. 42 was remarkable for the decisive victory gained by Antony and Octavius over the republican forces at Philippi, and the death of Brutus and Cassius. But the triumvirs were too ambitious, and hated one another too much, to be long united. Antony went into Asia to raise money for his soldiers, and during his absence Fulvia, his wife, quarrelled with Octavius. When Antony was in Asia, indulging himself in all manner of luxury, the famous Cleopatra inspired him with the most violent passion. Hearing of the quarrel between Fulvia and Octavius, and finding Octavius was become publicly his enemy, Antony entered into a confederacy with Sextus Pompeius, who was still master of Sicily. He then went into Italy to fight against Octavius; but Fulvia, who had been the author and promoter of this war, dying, Octavius and Antony came to an agreement. One of the conditions of this new peace was, that they should together attack Pompey, though the former had lately made an alliance with him. Antony then married Octavia, sister of Octavius, as a pledge of their renewed friendship, but returning soon after to his beloved Cleopatra, he sent back Octavia to her brother. Antony now assumed the state and ceremony of an Eastern prince. His invasion of Parthia had been attended with a severe defeat; but more fortunate in Armenia, he obtained possession of the person of king Artavasdes, and carried him to Alexandria. His arbitrary conduct having at length alienated many of his friends and supporters, Octavius seized the opportunity to accomplish his ruin. They engaged in the memorable sea-fight off Actium, on the 2d Sept. B.C. 31, when the untimely flight of Cleopatra with the greater part of the fleet hastened Antony's defeat. They fled together to Alexandria, where in the following year Antony, betrayed by Cleopatra and assailed by Octavius, put an end to his own life by falling on his sword. See CLEOPATRA.

ANTONOMASIA, from ἀντί and ὄνομα, a figure of rhetoric by which a substitution is used for a proper name. It may be either the employment of a patronymic, a characteristic epithet, or the substitution of another name for that of the individual. Thus Homer uses "Pelides" and "Atrides" for Achilles and Agamemnon; Aristotle is denominated "the Stagyrite;" Pope designates Charles XII. and Alexander the Great "the Swede," and "Macedonia's madman;" Thomson terms Charles "the frantic Alexander of the north."

ANTOSIANDRIANS, a sect of rigid Lutherans, who opposed the doctrine of Osiander relating to justification. These are otherwise denominated *Osiandromastiges*. The Antosiandrians deny that man is made just with that justice wherewith God himself is just; that is, they assert that he is not made essentially, but only imputatively, just; or, that he is not really made just, but only pronounced so.

ANTRIM, a maritime county in the northern extremity of Ireland, in the province of Ulster, situate between 54. 26. and 55. 12. 16. N. Lat. and 5. 47. and 6. 52. W. Long. It comprises, according to the Ordnance survey, an area of 745,177 acres or 1164 square miles, of which 503,288 are arable, 176,335 uncultivated, 10,358 in plantations, 1908 in towns, and, including a portion of Lough Neagh, 53,288 under water. In addition to the above, the county with the town of Carrickfergus contains 16,700 acres, or 26 square miles; of which 12,483 are arable, 4088 uncultivated, and 129 in the town, making the total area of the county 761,877. Antrim presents a considerable line of coast to the northern Ocean, by which it is bounded on the north, and the Irish Channel, which forms its eastern boundary; Carrickfergus Bay, or Belfast Lough, and the River Lagan, divide it from the county of Down. The winding shores of Lough Neagh and Lough Beg, together with the River Bann, form its boundaries on the west until the River Bann touches the liberties of Coleraine, which then complete the western boundary. In superficial extent Antrim is exceeded by eight other counties in Ireland, but the extensive county of Cork alone supports a more numerous population.

In 1584-5, the county was divided by the lord-deputy, Sir John Perrot, into eight baronies; but of late years, by the subdivision of six of the old baronies into upper and lower, it has been divided into fourteen baronies, viz., Antrim, Lower and Upper; Belfast, Lower and Upper; Cary Dunluce, Lower and Upper; Glenarm, Lower and Upper; Kilconway, Massareene, Lower and Upper; Toome, Lower and Upper. There are also smaller divisions, as parishes, granges, manors, and townlands. The number of parishes, and parts of parishes, is 75, all of which are in the diocese of Connor, except the parish of Aghalee, in the barony of Upper Massareene, which is in Dromore diocese. There are seven poor-law unions in the county,—Antrim, Ballycastle, Ballymena, Ballymoney (partly in Londonderry county), Lisburn (partly in Down county), and Larne. There is a revenue police-station at Ballymoney, and 21 coast-guard stations, with 145 officers and men. The headquarters of the constabulary force, which consists of 229 officers and men, are at Ballymena, the county being divided into six districts. Antrim is in the Belfast military district, the headquarters of which, and also of the county militia, are at Belfast. The fishery districts are Ballycastle and Carrickfergus, comprising 121 miles of maritime boundaries, which in 1852 had 764 registered vessels, employing 2468 men and boys. The amount of property valued under the Act 6th and 7th Will. IV. cap. 84 (Griffith's valuation), was L.479,934, and the net annual value of property rated to the poor is L.702,917. The county sends six members to the imperial parliament, two for the shire,—constituency, in 1851, under 13th and 14th Vict., c. 69, 8207; two for Belfast borough,—constituency 2697; and one for each of the boroughs of Carrickfergus and Lisburn, constituencies, 720 and 188.

The assizes, formerly held at Carrickfergus, are now held at Belfast, which has recently been proclaimed the county town. Quarter-sessions are held at Antrim, Ballymena, Ballymoney, Belfast, and Carrickfergus. There are three savings-banks in the county, Belfast, Gracehill, and Lisburn,

Antrim. the deposits in which amounted in 1851 to L.116,424, a sum exceeding that deposited in the savings-bank of any other county in Ireland except Cork. The principal towns are—Belfast, population in 1851, 100,300; Carrickfergus, 8543; Antrim, 2324; Ballymena, 6136; Larne, 3076; and Lisburn, 6569.

The earliest known inhabitants were of Celtic origin, and the names of the townlands or subdivision, supposed to have been made in the thirteenth century, are pure Celtic. In addition to the intrusion of the Danish marauders, who infested all the eastern part of Ireland, Antrim was exposed to the inroads of the northern Scots, who ultimately effected permanent settlements here. The antiquities of the county consist of cairns, mounts, or forts, remains of ecclesiastical and military structures, and round towers. The principal cairns are—one on Colin mountain, near Lisburn; one on Slieve True, near Carrickfergus; and two on Colinward. The cromlechs most worthy of notice are one near Cairngrainey, to the north-east of the old road from Belfast to Templepatrick; the large cromlech at Mount Druid, near Ballintoy; and one at the northern extremity of Ireland, Magee. The mounts, forts, and intrenchments, are very numerous. There are four round towers in the county: one at Antrim 95 feet high (of which part only is standing), in the churchyard of Armoy, about four miles from Ballycastle; one on Ram island in Lough Neagh 43 feet high, a portion of which has evidently fallen; and the fragment of one between Lisburn and Moira, near the old church of Trummery. Of the ecclesiastical establishments enumerated by Archdall, there are some remains of those of Bonamargy, Kells, Glenarm, Glynn, Muckamore, and White Abbey. The noble castle of Carrickfergus, together with some additions, is the only one in perfect preservation. There are, however, remains of other ancient castles, of which the most interesting is the old castle of Dunluce, remarkable for its great extent and romantic situation.

A large proportion of the surface of the county consists of mountains and bogs. The mountains, occupying about one-third of the area of the county, stretch from south to north, terminating on the northern shore in abrupt and almost perpendicular declivities; they attain their greatest elevation near the coast, having a gradual descent inland, so that many of the principal streams have their source near the sea and flow thence into Lough Neagh. The eastern portion of the county is mountainous, nearly destitute of wood and abounding in bogs, which, from their situation appear irreclaimable; this character also, in some measure, applies to the northern portion, and it is computed that about 120,000 acres are incapable of improvement. On the western side of the mountain range, the valleys expand to a considerable width and are of great fertility, especially that of Six-mile-water, stretching towards the town of Antrim and the beautifully undulating surface of the valley of the Lagan. As it approaches the River Bann, the inclination of the mountainous region becomes less rapid, and is occupied by turf bogs susceptible of improvement. In the southern part of the barony of Toome, and along the shores of Lough Neagh, lies the most extensive level tract of well cultivated and fertile land within the county. From Belfast to Carrickfergus, and from thence to Larne between the mountain range and the sea, are tracts of very fertile land. The most remarkable ranges of cliffs are those of perpendicular basaltic columns (see GIANT'S CAUSEWAY), which extend for many miles along the northern shore, and are most strikingly displayed in Fair Head and the Giant's Causeway.

Lough Neagh, the largest lake in the United Kingdom, and, excepting Lake Ladoga, Lake Vener, and the Lake of Geneva, the most extensive in Europe, is principally in the county of Antrim. It is about 20 miles in length, 12 in breadth, and 80 miles in circumference, comprising 98,255½ statute acres, of which 50,025 are in Antrim, and the remainder in the counties of Armagh, Down, and Londonderry. Its greatest depth is 45 feet; and, according to the Ordnance survey, it is 48 feet above the level of the sea at low water. The lower River Bann, which is obstructed by weirs and rocks, being the only outlet for the waters of the lake, the surrounding country is injuriously inundated in winter. The waters of Lough Neagh are supposed to possess petrifying powers, but it is probable that these exist in the soil, as petrifactions are only found in the lake near the shore, and are also found at considerable heights inland. It is connected with Belfast, Newry, and Coal Island by means of canals. North of Lough Neagh, and connected with it by a narrow channel, is Lough Beg or "the small lake," containing 3145 acres, partly in the county of Antrim. This lake is generally 15 feet lower than Lough Neagh, and contains 4 small islands, one of which, Ram Island, belongs to Antrim. Its banks are more diversified and pleasing than those of Lough Neagh, which, owing to the want of wood, are monotonous.

Antrim.

The Rivers Bann and Lagan, both of which rise in the county of Down and form the southern and western boundaries of the county of Antrim, are the only rivers of importance. The rivers strictly belonging to the county, none of whch are navigable, mostly rise in the mountains near the coast, and run into Lough Neagh. They are generally rapid streams, peculiarly valuable as furnishing water-power for turning the numerous corn, flour, and cotton mills established on their banks. Surrounded by a wild and troubled sea, about 7 miles from the northern coast off Ballycastle, lies the Island of Rathlin, 6½ miles in length and 1½ in breadth, of similar basaltic and limestone formation with the mainland in that district. It contains 3399 acres, one-fourth of which is arable, and in 1851 was inhabited by 783 persons, inhabiting 130 dwellings. On the northern coast of the island are some vestiges of a castle, said to have afforded refuge in 1306 to Robert Bruce, who, according to the legend, learned in this place a lesson of indomitable perseverance under difficulties, whilst observing the continued exertions of a spider in the construction of its web.

The county of Antrim is of exceeding interest to the geologist, both on account of its peculiar character, and because the arrangement and alternations of strata are so openly disclosed as to enable the geologist to observe the secrets of nature more closely than can be done elsewhere. The peculiarities of the county are the basaltic pillars, the whin-dikes, stupendous walls which cut through the precipices, and without much intermission, line the coast for a length of nearly sixty Irish miles, the basaltic hummocks, generally stratified, scattered over the face of the county, and of various magnitudes, from the gigantic mountain to the most diminutive hillock.

Besides basalt, there are found limestone, gypsum, coal, surturbrand or fossil wood, freestone, and marble. Chalk is not met with in any other part of Ireland. The fossil wood, or wood-coal, in most places, as at Ballintoy and Killymorris, is covered with columns of basalt. In burning it emits a disagreeable smell, resembling that of rotten wood. Notwithstanding the compressed state in which it is found, the bark and knots are quite distinct, and the rings denoting the annual growth of the wood may be counted. In some instances the roots of the trees may be traced. Their heads all lie to the east, and seem as if laid down by a storm. The Antrim coal district is situated in the northern extremity of the county; and in point of geological position, is remarkable from its association with the great basaltic mass which forms the characteristic of the neighbouring scenery, and differs from all the other coal districts in Ireland, as wanting

the underlying limestone, and resting directly on mica slate. The district extends to the west and south of the magnificent promontory of Fair Head, from Ballycastle to Murlough Bay. The workings at the Ballycastle collieries are probably the oldest in the kingdom. Dr Hamilton, in his letters on the north coast of the county of Antrim, relates that, in 1770, the miners accidentally discovered a passage cut through the rock. It was very narrow, owing to incrustations formed on its sides. On being sufficiently widened, some workmen went through it, and on minute examination this subterranean wonder was found to be a complete gallery which had been driven forward many hundred yards into the bed of coal, branching out into thirty-six chambers, dressed quite square, and in a workmanlike manner. Some remains of the tools, and even of the baskets used in the work were discovered, but in such a decayed state, that on being touched they fell to pieces. No tradition remaining in the neighbourhood of the mine having been anciently worked, the excavation must have been made at a very remote period.

The coal of some of the beds is bituminous, and of others anthracitous, but the quantity now remaining in the district is very small. Petrifactions are found in Lough Neagh, and valuable hones are made of the petrified wood. In the white sand on the shores of the lake are found very hard and beautiful stones, chiefly chalcedony, known by the name of Lough Neagh peebles, susceptible of a fine polish, and often converted into seals and necklaces.

Besides the fish usually found in fresh-water lakes, the char, a species of trout called dollagher, and the pullan, or fresh-water herring, are found in Lough Neagh, and swans, teals, widgeons, herons, bitterns, and several other kinds of birds frequent its shores.

The mineral waters of the county are in the neighbourhood of Antrim, Ballycastle, Belfast, Carrickfergus, and Larne, and may be generally described as chalybeates of various degrees of strength. No thermal springs have yet been discovered; a circumstance the more remarkable, as it is in the vicinity of basaltic or volcanic rocks that thermal waters are most frequently met with. There are thick beds of rock-salt and salt-springs near Carrickfergus. The chief bathing-places are Ballycastle, Cushendall, Cushendun, Glenarm, Port Ballintrae and Portrush. They are exposed to the easterly winds prevalent in spring, but are desirable summer residences. There is much variety of scenery in the county from the low and somewhat monotonous shores of Lough Neagh and the dreary bog and mountain land of the interior, to the wild romantic scenery of the northern coast, and the fantastically beautiful shores about Glenarm. The climate of Antrim is very temperate, and less rain falls than is generally supposed. The rain gauge at Belfast has varied in different years from 20 to 35 inches. The greatest height of the barometer between the year 1796 and 1809 was 31 inches, the lowest 28 inches. The greatest height of the thermometer during that period was 78·80, the lowest 25. The mean temperature of Belfast is about 50 degrees, or one degree higher than that of London. The phenomenon of the mirage, similar to the *Fata Morgana*, is often observed in the strait which separates the island of Rathlin from the mainland.

In 1712 the number of dwelling-houses in the county of Antrim was 19,268; in 1726, 18,916; in 1791 the number was 30,314, of which 22,353 paid the tax for one hearth, and the remainder were returned as inhabited by paupers unable to pay. According to the population returns, the county contained in 1813, 42,258 dwelling-houses and 231,548 inhabitants; in 1821, 270,883; in 1831, 325,615; in 1841, 354,153; and in 1851, 352,264, inhabiting 58,281 houses, being a decrease of 1889 persons, and 1084 houses since 1841.

The estates in Antrim are in general freehold, being either immediate grants from the crown, or held under those grants: the only exceptions are the properties held under the see of Connor. Some of the estates are very large. The Marquises of Hertford and Donegal, and the Antrim family, possess the fee of the greater part of the county. The estate of the first includes 11 parishes, containing nearly 80,000 English acres. The other chief proprietors are Lord O'Neill, Viscount Massereene, Captain Packenham, and Lord Templetown. The estate of the last is only leasehold under the Marquis of Donegal.

The farms in Antrim are usually small, but, as in other parts in Ireland, the number of small holdings has for several years been steadily on the decrease. In 1851 there were 395 holdings not exceeding 1 acre; 2443 above 1 and not exceeding 5 acres; 6996 between 5 and 15 acres; 7220 between 15 and 30 acres; and 5796 above 30 acres, making a total of 22,850 holdings, being 361 less than in the previous year.

The principal feature in the tillage system of a great part of the county is the potato fallow. The quantity of potato land is commonly regulated by the manure that can be collected: of late years the culture of potatoes has been much increased by the use of lime. After potatoes, wheat or oats are sown; if the latter, two or three crops are successively taken. When the ground is exhausted, potatoes are again planted, or the land is suffered to rest for a year or two, until it is covered with natural grass, in which state it is termed *lea*. The sowing of wheat is chiefly confined to the baronies of Belfast, Antrim, and Massereene.

Flax is also sown after potatoes, except in the lower or northern part of the county, and its cultivation is largely on the increase, although it still forms but a small proportion in the general crop. In 1847 the land in the county under the flax crop was 2516 acres, and in 1851, 11,912. The cultivation of wheat, oats, and barley is decreasing, whilst the culture of potatoes and other green crops, meadow and clover land and flax, increases annually. The export of flax from Belfast was in 1850, 1457 tons; in 1851, 4001 tons, and in 1852, 6258 tons, whilst the import of foreign flax has decreased owing to the greatly increased cultivation of flax in Ireland. The extent of land under crops in 1847 was 202,888 acres, and in 1851, 227,453 acres, being an increase of 12 per cent. in four years. In 1851 the number of acres under the several species of crop was as follows:—wheat, 9938; oats, 98,594; barley, 1397; beans, 4614; potatoes, 41,013; turnips, 13,302; mangel-wurzel, and other green crops not previously enumerated 2806; flax, 11,912; meadow and clover, 52,272. The total produce of corn, beans, and pease in 1851 was 78,779 tons, being a decrease of 17,123 tons since 1847; and the number of barrels of potatoes grown in 1851 amounted to 1,746,510, being the largest quantity produced in any county in Ireland excepting the four counties of Cork, Down, Mayo, and Tipperary. The minute subdivision of the land somewhat retards the progress of improvement in agriculture and agricultural implements.

There is now but little natural wood in the county. The woods of Portmore and Glenarm have long since yielded to the axe; and the extensive plantings at Antrim, Templepatrick, Ballyclare, and Clementshill, have shared a similar fate. Many thriving plantations of trees have, however, been planted of late years near noblemen and gentlemen's seats, which already add much to the appearance of the face of the country. The plantations of Lord O'Neill at Shanescastle and Claggan, and those of the late Lord Macartney near Lochguile, are the most extensive. On the Hertford estate, near Lough Neagh, many orchards are planted.

The cattle of Antrim have no feature to distinguish them

as being allied to any particular stock. Of late years, considerable attention has been paid by gentlemen farmers to the improvement of the breed, by crossing with the Dutch, Leicester, and Ayrshire cattle, which is said to have improved much those kept for milk, and large quantities of butter are annually exported from Belfast. Sheep are little attended to, and are mostly of an inferior kind. Few goats are kept, and those chiefly by cottagers. Pigs are reared and kept in considerable numbers, and on these the small farmers and cotters depend chiefly to make up their rents; so that it is not uncommon to find from two to eight or ten of these animals about a farmer's house. During the salting season, which may be said to commence in September and end in May, the number brought to market is very large. In 1851, the live-stock in the county consisted of 27,673 horses, 450 mules and asses, 131,818 cattle, 42,361 sheep, 43,528 pigs, 1054 deer, 1609 goats, and 237,059 poultry, of the total value of L.1,186,762.

Antrim has long been distinguished for its linen manufacture, which may still be considered the staple manufacture of the county. It is a peculiarity of this occupation that it does not remove the peasant from the comforts and healthiness of rural life. In Antrim the weaver and the labourer of the soil are united in the same person. Many weavers have small farms, and only employ themselves in weaving during the intervals of their farming occupations; and almost all who pursue this occupation possess gardens and ground for potatoes. Formerly the wages for weaving a fine web varied from 14s. to 20s., but the rate is now much less, and consequently many weavers have become day labourers. The price of linen yarn, which formerly sold at 10d. or 1s. per hank, is now much reduced. This is in a great measure owing to the spinning of flax by machinery, which of late years has much increased. In 1841 there were about 240,000 spindles in operation, and now upwards of 500,000 are employed. The quantity of linen yarn exported from Belfast in 1852 was 6,679,680 lb. in 5963 bales, being an increase of 1962 or 2,185,440 lb. over the quantity exported in 1850.

Cotton spinning by jennies was first introduced in 1777, by Robert Joy and Thomas M'Cabe of Belfast, under the direction of a female spinner from Glasgow, and in 1800 it was computed that upwards of 13,000 people were directly employed in the cotton manufacture, and including others indirectly employed, the number was estimated at 27,000, within a circuit of ten miles, comprehending the towns of Belfast, Lisburn, and Carrickfergus. For many years after the introduction of the trade, the greater part of the yarn used for warps, and much of the weft yarn, was imported from Manchester or Scotland, but of late years cotton yarn has been exported from Belfast. The cotton manufacture has not increased of late years in Antrim.

A great source of employment for females has latterly sprung up in the working of patterns on muslin with the needle. Belfast is the centre of this trade, but large numbers of females are employed in various parts of Ireland in the production of these sewed muslins, and the gross value of the goods, when manufactured, amounts to about L.1,400,000. There are also extensive paper-mills in the county, and various manufactures in connection with the trade of the district. The exports are linen, linen yarn, all kinds of grain, pork, bacon, hams, beef, butter, eggs, lard, potatoes, soap, and candles.

There are extensive salmon-fisheries at Carrick-a-Rede, near Balintoy, along the coast north of Glenarm, and in the Rivers Bann and Bush. These fish frequent the other rivers of the county except the Lagan. All the rivers abound with eels, which are chiefly taken at weirs in the River Bann, where they are very plentiful.

Antrim has been supposed to contain a greater proportion of Protestants than any other county in Ireland; and of the Protestants a very great proportion are Presbyterians. The greater part of these are in connection with the general Synod of Ulster, the others are *Remonstrants*, who separated from the Synod in 1829—United Presbyterians, Covenanters, Independents; and at Gracehill, near Ballymena, there is a Moravian settlement. In several parishes, however, a decided majority are Roman Catholics.

The number of children attending schools in 1841 was, in rudimental schools, males 9737, females, 7743; in superior schools, males, 794, females, 448; total, 18,722. In 1851 there were 339 national schools in operation, attended by 28,763 children, 15,746 males, and 13,017 females. The educational establishments in Belfast are numerous and well conducted, including the Belfast Academy, the Royal Academical Institution, the Lancasterian or Ragged Schools, the National Schools, the Ulster Institution for the Deaf and Dumb and the Blind, the Educational and Industrial School, the Queen's College, and the Government School of Design.

The character of the people of Antrim reveals their Scottish origin. They have not the devotion to pleasure and sociality which is observable in other portions of the island, wanting in consequence some of the southern polish, but compensating in depth and solidity for any deficiency in superficial qualities.

Antrim, a town of Ireland, in the county of the same name, situated half a mile from Lough Neagh, on the banks of the Six-mile-water, in one of the most fertile and beautiful valleys of the county, 13 miles north-west of Belfast, and 106 north of Dublin. It gives the title of earl to the noble family of MacDonnell, and prior to the Union was a potwalloping borough, returning two members to Parliament by virtue of letters patent, granted to the inhabitants in 1666, by Charles II. It was under the patronage of the Skeffington family.

Although much improved of late years, there is nothing in the town particularly worthy of notice; but the environs, including Shane's castle and the grounds of Massareene castle, possess considerable interest. About a mile from the town, surrounded by wood, above which rises its gray conical head, is one of the most perfect of the round towers of Ireland. It is 95 feet high, and 49 in circumference at the base. Markets are held each Tuesday and Thursday, and fairs on January 1, May 12, and November 12. In 1851 the town contained 504 dwelling-houses, and 2324 inhabitants. The manufacture of paper has been carried on here for many years, and there are flour and meal mills near the town. The Belfast and Ballymena railway passes a short distance from the north of the town. On the 7th of June 1798 a smart action was fought in the town between the king's troops and a large body of rebels, in which the latter were defeated. In this action Lord O'Neill was mortally wounded by a pike. (H. S—R.)

ANTWERP (in French, Anvers), one of the provinces of the kingdom of Belgium, is bounded on the north by North Brabant, on the east by Limburg, on the south by South Brabant, and on the west by Zealand and East Flanders. It contains 824 geographical square miles, or 283,311 hectares, equal to 770,924 English imperial acres, and is divided into 3 arrondissements, 22 cantons, and 146 communes. The province is an extensive plain scarcely diversified by an elevation. The arable land, which contains a great proportion of sand, is very fertile, but a considerable part of the country is morass and heath, particularly in the north and east. The population in the beginning of 1851 amounted to 420,556.

Antwerp, one of the three arrondissements of the above

province, comprehends 7 cantons and 57 communes. In 1851 it had a population of 199,891.

Antwerp, the capital of the above arrondissement and province, is situated on the right bank of the river Schelde, 26 miles north of Brussels, in Lat. 51. 13. 16. N. Long. 4. 24. 10. E. The city is well built, in the form of a crescent, containing many fine streets and squares, and is fortified. The houses are large and handsome, and some of its public buildings are of great splendour and antiquity. The citadel, a strong pentagonal structure, was built by the Duke of Alva in 1567, and is celebrated in recent times for the defence made here by General Chassè in the end of the year 1832. One of the most beautiful specimens of Gothic architecture in the Netherlands is the cathedral of Notre Dame, founded in the early part of the fifteenth century, but not finished till the sixteenth: it is 500 feet long, 250 feet wide, and has a spire 403 feet high. Nor is the interior inferior in grandeur to the exterior; besides other pictures it possesses several by Rubens, one of which is the celebrated "Descent from the Cross." The church of St James is also very splendid in its internal decorations of marbles, painted glass, carved wood, and monuments. Behind the high altar, and covered by a slab of white marble, is the tomb of Rubens, by whom the "Holy Family" which adorns the altar was painted. Sir Joshua Reynolds observes, that for effect of colour this picture yields to none of Rubens's works. The churches of St Paul, St Andrew, and St Augustine, likewise contain some fine paintings by Rubens and others of the old masters. The exchange, built in 1531, is one of the finest buildings of the kind in Europe; and is said to have been chosen by Sir Thomas Gresham as a model for the Royal Exchange in London. The town-house is a handsome edifice in the Italian style, and exhibits the five orders of architecture, one over the other. Antwerp contains many educational and literary institutions. It has a Royal Athenæum, in which most of the usual branches of literature and science are taught, a higher school, schools of navigation, medicine, and surgery, a botanic garden, a public library, and various scientific and literary societies. It has also a Royal Academy of the Fine Arts, which affords gratuitous instruction in painting, sculpture, architecture, and engraving. At the competition which takes place in one of these arts annually, the laureate receives a pension of 2500 francs for four years, to enable him to pursue his studies in Germany, France, and Italy. The second prize is a gold medal of the value of 300 francs. Among the numerous works in the Academy of Painting, are 12 or 14 fine pictures by Rubens, 6 by Vandyck, and several by Titian, Teniers, Jordaens, Quentin Matsys, and other masters. The charitable institutions include a foundation for foundlings, besides several other hospitals and asylums, courts of assize, commerce, &c.

Antwerp enjoys many facilities for commerce. The Schelde at this point is about 2200 feet broad, with a depth of from 30 to 40 feet at ebb tide, and a rise at spring tides of from 12 to 14 feet; and as this depth increases towards the sea, the largest vessels can, by means of the canals, come up to the wharfs. The advantageous situation of Antwerp did not escape the penetrating eye of Napoleon, who spared no labour or expense to render it the rival of London in commerce, and of Portsmouth as a military establishment. The sums expended by him for this purpose are said to have amounted to L.2,000,000 sterling, which he declared to be nothing to what he intended. On the downfall of Napoleon, the dockyard, with its fortifications, was destroyed; but two large basins on the north side of the town, of the respective areas of 17 and 7 English acres, have been preserved. They are capable of admitting ships of the line; and as commercial docks they are now of the greatest service to trade and navigation. The junction of this city with Brussels by a railway, which was opened in 1836, has been of great advantage to both cities. In 1850 the number of ships that entered its harbour was 1406, of the aggregate burthen of 233,760 tons; and the number that left the port was 1456, with the gross burden of 242,884 tons. The imports are principally coffee, grain, seeds, raw sugar, cotton, tobacco, and colonial produce; the exports are flax, woollen goods, refined sugar, metals, glass, and tallow. It has regular steam-communication with London and Hull.

The manufactures of Antwerp are various and considerable, the principal being lace, silk, linen, cotton, tapestry, galloon, twine, sugar, white lead, litmus, starch, printers' ink, and malt liquors. The lapidaries of Antwerp are celebrated for their skill in cutting diamonds. The shipbuilding is considerable, and the timber used for that purpose is principally brought by water from the interior. The National Bank of Belgium has a branch here.

Antwerp, according to the general census of 15th October 1846, contained 13,626 houses, and 88,487 inhabitants, of whom 85,961 were Roman Catholics, 1312 Protestants, and the remainder either Jews, or belonging to other sects. The greater number of the inhabitants speak Flemish or Dutch. According to the above census 81,947 spoke Flemish or Dutch, and 3915 French, or Walloon. The number of births during the year 1850 was 3250, of whom 144 were still-born; the deaths amounted to 1914; and the population, in the beginning of 1851, was 95,501.

The present commercial condition and importance of Antwerp is far inferior to what it was several centuries ago. About the end of the fifteenth century it was the richest and most flourishing city in Europe. No fewer than 500 ships would sometimes enter the port in one day, and as many as 2500 vessels might be seen lying in the river at one time. On an average, 500 waggons laden with goods daily entered its gates; and above 500,000,000 of guilders were annually put in circulation. It had then 200,000 inhabitants; and indeed all that is said of its commercial prosperity and the immense riches of its merchants, is almost incredible. The first blow to its prosperity was its capture by the Spaniards in 1576, when it was plundered for three days; and nine years afterwards, when besieged and ultimately captured by the Spaniards under the Duke of Parma, its trade was utterly ruined. After this event the greater number of its merchants and principal inhabitants removed to Amsterdam or other places. The Dutch, with the view to lessen the importance of a place which had now fallen into the hands of their enemies, built ports on the river in order to intercept such vessels as might attempt to get to Antwerp. By the terms of the peace of Westphalia in 1648, the commerce of its harbour was closed. In 1794 it fell into the hands of the French, who opened its port, and made it the capital of the department of the two Nethes. It remained in their possession till 1814, when it was surrendered, after the treaty of Paris, by Carnot, who up to this time had defended it with great spirit and bravery against the allied army under the command of Graham. From 1815 to 1830, Antwerp, with the rest of Belgium, united with Holland to form the kingdom of the Netherlands; and during this period its commerce increased so rapidly as to excite the jealousy of Amsterdam. For the part which Antwerp bore in the revolution of 1830, which dissolved the union between Holland and Belgium, see Netherlands.

Among the distinguished natives of the place are Vandyck, the two Teniers, Jordaens, Floris, the geographer Ortelius, and the engraver Edelinck. Here Rubens also, though not a native, received his education, and resided.

ANUBIS, a symbolical deity of the Egyptians, was re-

garded as the faithful companion of Osiris and of Isis. Temples and priests were consecrated to him, and his image was borne in all religious ceremonies. Cynopolis, situated in the Lower Thebais, was built in honour of Anubis. The temple in which he was worshipped, and where his festivals were celebrated with great pomp by the priests, no longer exists. The dog was consecrated to him as his living representative; and a number of these animals were kept in the temple, and fed upon sacred aliment. Strabo, in his 17th Book, speaks of the worship of Anubis in the Cynopolitan nome and city, "where honour and a certain sacred food is allotted to dogs." An event, however, related by Plutarch, brought them into considerable discredit with the people:—Cambyses having slain the god Apis, and thrown his body into a field, all animals respected it except these, which alone ate of his flesh. Recent investigation, and the study of Egyptian sculptures, seem to prove that the head on the human shoulders of Anubis are not those of any domestic dog, but of the jackal.—See Wilkinson's *Egypt*. Anubis was recognised by the Greeks as a character of Hermes.

Cynopolis was not the only city which burned incense on the altars of Anubis. He had chapels in almost all the temples. In solemnities, his image always accompanied those of Isis and Osiris. Rome having adopted the ceremonies of Egypt, the Emperor Commodus, to celebrate the Isiac feasts, shaved his head, and himself carried the god Anubis. The statue of this god was either of massive gold or gilt, as well as the attributes that accompanied him. Anubis signifies *gilded*. The denomination was mysterious; and the Egyptian priests, it would seem, had not given it without reason.

The signification of this emblematical deity is thus explained by Plutarch: "The circle which touches and separates the two hemispheres, and which is the cause of this division, receiving the name of *horizon*, is called *Anubis*. He is represented under the form of a dog, because that animal watches day and night." Clemens of Alexandria, who was well informed in the mystic theology of the Egyptians, favours this explanation. "The two dogs," says that writer, "are the symbols of two hemispheres which environ the terrestrial globe." He adds in another place,—"others pretend that these animals, the faithful guardians of men, indicate the tropics, which guard the sun on the south and on the north, like porters."

According to the former of these interpretations the priests, regarding Anubis as the horizon, gilded his statue, to mark that this circle, receiving the first rays of the sun, appears sparkling with brightness on his rising, and that at his setting he reflects his last rays upon the earth. They said, in their sacred fables, that Anubis was the son of Osiris, but illegitimate. In fact, he only gives to the earth a borrowed light, and cannot be esteemed, like Horus, as the father of the day, or as the legitimate offspring of Osiris. It may be added, that the visible horizon, turning with the sun, is his inseparable companion.

In the latter of these explanations, where Anubis represents the tropics, he is also the faithful guardian of Isis and Osiris. In fact, the course of the sun and of the moon is contained between the circles wherein the solstices are performed. They deviate neither to the right nor left. These limits, assigned by the Author of nature, might therefore, in hieroglyphic language, be represented by a divinity with the head of a dog, who seemed to oppose the passage on the side of the two poles. The other opinion, notwithstanding, seems more natural, and more analogous to the ideas of the priests.

Upon the whole, it is reasonable to imagine that Anubis at first was only a symbolical image, invented by astronomers to give a sensible expression of their discoveries; that afterwards the people, accustomed to see it in their temples, which were the depositories of science, adored it as a deity; and that the priests favoured their ignorance by connecting it with their religion. The worship of Anubis being introduced, the dog became his emblem. Almost all the gods of the Gentiles have originated in this manner.

ANVIL, in *Smithery*, and other manufactures of the malleable metals, is an instrument on which substances are laid for the purpose of being hammered.

For some purposes anvils are made of cast iron; but when the face of the anvil is required to possess great hardness, or a bright surface, it is made of wrought iron and faced with steel. The core or body of wrought-iron anvils is prepared at the forge, where malleable iron is first formed into bars, or into masses for any particular purpose. The body of the anvil is formed by welding a number of smaller masses together under the forge-hammer. These are rude blocks of different sizes, according to the size of the anvil. Smaller masses are also furnished in this way, which the anvil-maker occasionally welds to the large blocks, for giving to the anvil any particular form.

The fire-place or hearth of the anvil-maker's forge is similar to the common smith's forge. His bellows are not double, like the latter. His fuel is cork, which produces a great heat without much flame. Adjacent to the hearth is a crane, which, turning upon a pivot, brings the heated masses of iron from the fire to the anvil. The latter is a large mass of cast metal, about 18 inches square on the face, and about a foot from the ground. When the core of the anvil to be formed is heated, the first thing is to make three square holes, one in the bottom, and one at each end of the anvil. These holes are about $1\frac{1}{4}$ inch long, 1 inch broad, and about 2 inches deep. They are for the purpose of receiving a bar of iron, which is connected with the crane by which the anvil is held in the fire, and by which it is turned and guided while forming with the hammers.

The common smith's anvil is generally made of seven pieces, namely, the core or body; the four corners, for the purpose of enlarging its base; the projecting end, which contains a square hole, for the reception of a set, or chisel, to cut off pieces of iron; and the seventh piece is the beak, or conical end, used for turning pieces of iron into a circular form, welding hoops, &c. These pieces are each separately welded to the core, and hammered so as to form a regular surface with the whole. When large pieces are required to be welded to the core, one fire is not sufficient to heat both at the same time. In this case two hearths are employed. The core and the piece are both raised to a welding heat. The piece being put into its place, is hammered by a quick succession of blows till it adheres. The whole is again heated and hammered till the due form is obtained. The hammering is performed by a number of men at the same time, each using a large swing-hammer. The blows follow each other in regular succession, great experience and care being required to prevent the hammers from coming in contact with each other.

When the anvil has received its due form, it then requires to be faced with steel. This is performed by first preparing the steel face to the size of the anvil. The anvil is then heated to a strong welding heat in one fire, while the steel facing is heated in another, but not so hot as the iron. The anvil is now brought out and placed in a proper position, and the facing is brought to it. The surfaces which are to be brought together are brushed, and the facing is then laid on and hammered as rapidly as possible, till it is closely united. The whole is finished by repeated heating and hammering.

The next process is that of hardening the anvil. This consists in heating the face, in particular, to a full red heat, and quenching it in cold water. When a stream of water

Anville.

can be employed it is better. Where this cannot be had, the mass of water should be great, and the anvil moved about as quickly as possible. The facing should be laid on as thin as it can be firmly welded; when it is too thick it is apt to crack in the hardening.

After hardening, the face is ground till it is perfectly even, and the edges made sharp or round, as may be required. When the anvil is required for planishing metals, it is polished with emery, and afterwards with crocus.

The smith's anvil is generally placed loose upon a wooden block, the root-end of an oak-tree being preferred. The anvils used in cutlery and for files are fastened into a large block of stone, which is doubtless better than having the anvil loose upon a small block. The more firmly the anvil is connected with the earth and the substances it stands upon, the greater will be the effect of the blow of the hammer. (C. S—R.)

ANVILLE, Jean Baptiste Bourguignon d', a French geographer of the highest eminence, and perhaps unsurpassed in any age. This celebrated man was born at Paris on the 11th of July 1697. His passion for geographical research displayed itself from his earliest years. At the age of 12, while reading the Latin authors at college, he amused himself with drawing maps of the countries which they described. While he was thus busily employing himself one day in the class, his master observed and was about to punish him; but upon casting his eye upon the performance, he immediately judged him to be rather deserving of encouragement. D'Anville from this time devoted himself entirely to geography, particularly that of the ancient world; and at the age of 22 he began to delineate maps which attracted the attention of the most eminent geographers.

There are two modes by which problems in geography may be solved; one mathematically, by astronomical observation or geometrical measurement; the other historically, by the distances of places inferred from the narrative of historians and travellers. The former is certainly the most satisfactory, and would supersede every other, could it be extended over the whole surface of the globe. But, notwithstanding the splendid progress made since the era of D'Anville, it is still far from such a degree of perfection. In all countries the bulk of the positions must be filled up, and in some the whole must be constructed from mere historical materials. Perhaps there is no department of science which requires greater extent of knowledge and accuracy of judgment. The variety of sources out of which the materials must be drawn is almost infinite; and their application is equally nice and difficult. It must be regulated by a complete acquaintance with all the modes of measurement used by all nations; by a careful notice of those errors and contradictions which naturally arise from a partial and limited observation; and by the marking of certain delicate processes in the human mind, by which space and distance are sometimes diminished, and more frequently exaggerated. In the skilful geographer, sound natural judgment, enlightened by experience, creates, as it were, a new sense, which enables him to see consistency amid a labyrinth of contradictions, and to elicit truth from a multitude of statements that are all erroneous. This art may be said to have originated with D'Anville, and to have been brought by him to its highest perfection.

The course of study on which D'Anville entered was truly immense. Works professedly geographical formed the least part of it; those of all the ancient and modern historians, travellers, narrators of every description, were assiduously examined. He studied, but only for the sake of the occasional geographical lights which they afforded, the philosophers, orators, and poets; for it was remarked that in perusing these masterpieces of human genius, he was totally indifferent to everything which did not tend to fix a geographical position. The object of this immense labour was to effect a complete reform in the science of geography; to banish the system of copying blindly from preceding maps, and never to fix a single position without a careful examination of all the authorities upon which it rested. By this process he detected many and great errors in the works of his most celebrated predecessors, while his own accuracy was soon attested on all sides by the travellers and mariners who had taken his works as their guide. His principles led him also to another innovation, which was that of omitting every name for which there existed no sufficient authority. The public were at first amazed at seeing vast spaces, which had before been covered with countries and cities, suddenly reduced to a perfect blank; but they soon recognised that this was the only accurate course, and that the defect lay in the science, not in the geographer.

Anville.

D'Anville was at first employed in the humbler task of illustrating by maps the works of different travellers, such as Marchais, Charlevoix, Labat, and Duhalde. The question respecting the figure of the earth coming to be much agitated, he published, in 1735 and 1736, two treatises, with a view to illustrate it. But this attempt to solve a geometrical problem by historical materials was eminently unsuccessful. Maupertius having gone to measure a degree within the polar circle, the result was found directly opposite to our geographer's prediction. This, however, was considered by the intelligent public rather as fixing limits to his mode of investigation, than as implying any want of diligence and ability in its employment.

Any loss of reputation which this failure might occasion was completely retrieved by his map of Italy, published in 1743. It was marked by a species of investigation often employed by D'Anville with peculiar success. This consisted in the application of ancient materials to correct the existing geography. By the diligent study of the Latin authors he was enabled to trace numerous errors which had crept into the delineation of this interesting country. A trigonometrical survey which Pope Benedict XIV. almost immediately after caused to be made in the Ecclesiastical States confirmed, in a surprising degree, all these alterations. On this occasion he first set the example, which cannot be too much applauded, of accompanying the map with a memoir exhibiting a view of the data on which it had been constructed.

He now applied himself to ancient geography, always his favourite department, and the aspect of which, under his hands, was soon completely changed. He illustrated successively, by maps, all the countries known to the ancients, among which Egypt attracted his peculiar attention. To render these labours more extensively useful, he published in 1768 an *Abridgment of Ancient Geography*. His attention was finally turned to the middle ages, which were illustrated by his *States formed in Europe after the fall of the Western Empire*, and by some other works equally learned. Entirely devoted to geographical inquiries, the appearance of his successive publications formed the only events by which his life was diversified. From causes which are not explained, he was late in being admitted into the literary societies. In 1754, at the age of 60, he became a member of the Academy of Inscriptions and Belles Lettres, whose transactions he enriched with many papers. In 1775 he received the only place in the Academy of Sciences which is allotted to geography; and in the same year he was appointed, without solicitation, first geographer to the king. But these honours came too late to gladden a life which was now drawing to its utmost verge. His last employment consisted in arranging his collection of maps, plans, and geographical materials. It was the most extensive in

Europe, and had been purchased by the king, who, however, left him the use of it during his life. This task performed, he sunk into a total imbecility both of mind and body, which continued for two years, and ended only with his death in January 1782, when he had nearly reached the great age of 85.

D'Anville, with the qualities which form the great geographer, united all the essentials of an honourable and worthy character. The advancement of the science to which he had devoted himself formed almost the sole passion of his life; and, mingling little with society, he contracted peculiarities which solitary study is but too apt to engender. He talked with little interest on any subject except geography. This topic necessarily led to that of his own discoveries, on which he was never weary of expatiating. He boasted without any reserve of the services which he had rendered to that science, using not unfrequently the expression of Augustus, "I found it of brick and left it of marble." He, however, did full justice to the merit of those who excelled in other branches of knowledge; and to such as furnished him with materials for his researches his gratitude was unbounded. His published memoirs and dissertations amounted to 78, and his maps to 211. (H. M.)

ANWARI, a very eminent Persian poet, born of poor parents in Khorassan early in the twelfth century. He enjoyed the especial favour of the Sultan Sandjar, whom he attended in all his warlike expeditions. On one occasion, when the sultan was besieging a rebellious vassal in the fortress of Hazarasp, a fierce poetical conflict was maintained between Anwari and his old rival Rasheedi the poet, who was an inmate of the beleaguered castle, by means of verses fastened to arrows. Anwari died at Balkh in the year 1200. He is considered as one of the best and purest of the Persian poets. His chief work, *The Tears of Khorassan*, has been translated into English verse by Captain Kirkpatrick, in the *Asiatic Miscellany*.

ANWEILER, or Annweiler, the capital of the canton of the same name, in the district of Landau in Rhenish Bavaria. Population 2800, employed in various manufactures. Near it are the ruins of the castle of Triefels, where, under the French emperors of Germany, the crown jewels were kept, and where our Richard Cœur de Lion, in 1193, was detained as a prisoner. Lat. 49. 13. N. Long. 8. E.

ANZIN, a village of France, department of Nord, close to Valenciennes. Its coal mines, which are the most extensive in France, were discovered in 1734, and gave employment to 16,000 persons. It has also several iron foundries and glass works. Pop. in 1846, 3132.

AORIST, from α, priv., and ὅρος, a boundary, in *Grammar*, a tense peculiar to the Greek language, expressing action in an indeterminate manner, without any regard to past, present, or future.

AORISTIA, in the *Sceptic Philosophy*, denotes that state of the mind wherein we neither assert nor deny anything positively, but only speak of things as seeming or appearing to us in such a manner. The aoristia is one of the great points of scepticism to which the philosophers of that denomination had continual recourse by way of explication or subterfuge. Their adversaries the dogmatists charged them with dogmatizing, and asserting the principles and positions of their sect to be true and certain.

AOSTA, formerly a duchy of Piedmont, but now a province of the kingdom of Sardinia, lying south of Valais and east of Savoy. It has an area of 1025 geographical square miles, and in 1848 contained 81,232 inhabitants. The country is in general mountainous; but there are several valleys of great extent, particularly the *Val d'Aosta*. By the industry of the inhabitants these low grounds are very fruitful in wine, oil, and pasture; and the mountains abound in iron and copper.

Aosta, the chief town of the foregoing duchy, and the see of a bishop. It is situated on the river Doria, at the foot of the Alps, where the great commercial roads from Savoy and the Valais to Piedmont, over the Great and Little St Bernard, meet each other. The town, though large, is meanly built. It is remarkable for several monuments of the Romans, and for being the birthplace of Anselm, archbishop of Canterbury. Long. 7. 20. E. Lat. 45. 44. N. Pop. 7120.

APÆDUSIA (α, priv., and παιδεύω, I instruct), denotes ignorance or unskilfulness in what relates to learning and the sciences. Hence also persons uninstructed and illiterate are called *apædeutæ*. The term *apædeutæ* was particularly used among the French in the time of Huet, when the men of wit at Paris were divided into two factions, one called by way of reproach *apædeutæ*, and the other *eruditi*. The *apædeutæ* are represented by Huet as persons who, finding themselves either incapable or unwilling to undergo a severe course of study in order to become truly learned, conspire to decry learning, and turn the knowledge of antiquity into ridicule, thus making a merit of their own incapacity. The *apædeutæ* in fact were the men of pleasure, the *eruditi* the men of study. The *apædeutæ* in everything preferred the modern writers to the ancient, to supersede the necessity of studying the latter. The *eruditi* derided the moderns, and valued themselves wholly on their acquaintance with the ancients.

APAGOGE, in *Mathematics*, is sometimes used to denote a progress or passage from one proposition to another, when the first, having been once demonstrated, is afterwards employed in the proving of others.

APAGOGICAL Demonstration, an indirect way of proof, by showing the absurdity of the contrary.

APAGON, a genus of fossil fishes, in the Cycloïd Order of Agassiz.

APAGYNOUS (from ἅπαξ and γονή), a term applied to plants that fructify but once. It is the same as *Monocarpic*.

APALACHIAN MOUNTAINS. See Allegany Mountains.

APAMEA, in *Ancient Geography*, the name of several Asiatic cities:—1. A large city of Syria, capital of Apamene, in the valley of the Orontes. In the time of the Crusades, it was called Famieh, and is supposed to be represented by the extensive ruins at Kulat-el-Mudyk. 2. A city on the Tigris, probably near its confluence with the Euphrates, where the modern Korna now stands. 3. In Osroëne, on the left bank of the Euphrates, opposite to Zeugma. 4. The name given to Myrlea of Bithynia, by Prusias I., who rebuilt it. Its ruins lie near Medania. 5. A town of Phrygia, the site of which is fixed at Denair. 6. A Greek city of Parthia, in the district of Choarene.

APANAGE (*Apanagium, Apanamentum*, and probably derived from *panis*, or *panaggio*, provision), lands or feudal superiorities assigned to the younger princes of a reigning family. The apanage descended to the lawful heirs-male; and in their default it reverted to the crown. It was customary for the sons of princes to derive their surnames from the apanage.—See Pasquier's *Recherches*, l. 2, c. 18; l. 8, c. 20. Henault's *Hist. de France*, anno 1283.

APATHY, among the *Ancient Philosophers*, implied an utter privation of passion, and an insensibility of pain. The word is compounded of α, priv., and πάθος, *affection*. The Stoics affected an entire apathy: they considered it as the highest wisdom to enjoy a perfect calmness or tranquillity of mind, incapable of being ruffled by either pleasure or pain. In the first ages of the church the Christians adopted the term *apathy* to express a contempt for all earthly concerns, a state of mortification such as the gospel prescribes. Clemens Alexandrinus, in particular, brought it greatly into use; thinking thereby to draw to Christianity the philosophers who aspired after such a sublime pitch of virtue.

APATITE, a mineral often crystallised in six-sided prisms. It is a phosphate of lime. See MINERALOGY.

APATURIA, in *Antiquity*, a solemn feast celebrated by the Athenians in honour of Bacchus. The word is usually derived from ἀπάτη, *fraud*. It is said to have been instituted in memory of a fraudulent victory obtained by Melanthus of Messenia, over Xanthus, king of Bœotia, in a single combat, which they agreed upon to put an end to a debate between the Athenians and Bœotians respecting their frontiers.

Other authors give a different etymology of this feast. They tell us that the young Athenians were not admitted into the tribes on the third day of the apaturia, till their fathers had first sworn that they were their own children; and that till that time they were supposed in some measure to be without fathers, ἀπάτορες; whence the feast, say they, took its name. Xenophon, on the other hand, informs us that the relations and friends met on this occasion, and joined with the fathers of the young people who were to be received into the tribes; and that from this assembly the feast took its name; that in ἀπατούρια, the α, far from being a privative, being here a conjunctive, signifies the same thing with ἅμα, *together*. This feast lasted three days: the first day those of the same tribe made merry together; and this they called δορπία. The second day, which they called ἀνάρρυσις, they sacrificed to Zeus and Athena. The third day, which they called κουρεῶτις, such of their children as had not been registered were admitted into their tribes. The following day, as in other festivals, was called ἐπίβδα.

APAULIA, in *Greek Antiquity*, the third day of a marriage solemnity. It was thus called because the bride, returning to her father's house, lodged apart from the bridegroom (ἀπαυλίζεσθαι τοῦ νυμφίου). Some will have the apaulia to have been the second day of the marriage, viz., that whereon the chief ceremony was performed; thus called by way of contradistinction from the first day, which was called προαύλια. On the day called ἀπαύλια (whenever that was) the bride presented her bridegroom with a garment called ἀπαυλιστήρια.

APAUMEE, in *Heraldry*, denotes one hand extended with the full palm appearing, and the thumb and fingers at full length.

APE. See MAMMALIA, *Index*.

A-PEAK, in *Seamen's Language*, signifies perpendicular; thus the anchor is said to be a-peak when the stem of the ship is brought directly over it by drawing in the cable.

APEL, or APELLUS, JOHANN, professor of law in the University of Wittemberg, and one of the most zealous partisans of Luther in promoting the Reformation, was born at Nuremberg in 1486. Having married a nun while canon of Warzburg, he published his *Defensio Jo. Apelli pro suo Conjugio; cum præf. Lutheri*, &c. 1523, 4to. His other works are entitled *Methodica Dialectices Ratio, ad Jurisprudentiam accommodata*, Norimb. 1535, 4to: and *Brachylogus Juris Civilis, sive Corpus Legum*, a work much esteemed, and once ascribed to the Emperor Justinian. He died in 1540.

APELLES, the most celebrated painter of antiquity. He was born, according to Ovid and Pliny, in the island of Cos, and flourished in the time of Alexander the Great, whom he probably accompanied in his Asiatic expedition. Alexander gave him a remarkable proof of his regard; for when he employed Apelles to draw Campaspe, one of his mistresses, having found that he had conceived an affection for her, he resigned her to him. Either she, or Phryne, is said to have been the model of his Venus Anadyomene. It is well known that Alexander forbade any one besides Apelles to paint his portrait. We are not, however, to conclude from this that Alexander was a more skilful judge of painting than he was of poetry. Like Augustus, he cherished the fine arts more from vanity than taste. A remarkable proof is given of this prince's inability to discern merit, and of the painter's freedom in expressing the mortification he felt when a work of his was not sufficiently commended. "Alexander," says Ælian, *Var. Hist.*, lib. ii. c. 3., "having viewed the picture of himself at Ephesus, did not praise it as it deserved. But when a horse was brought in, and neighed at seeing the figure of a horse in the picture, *O king!* said Apelles, *this horse seems to be a far better judge of painting than you.*" It is related that on one occasion he had painted a horse returning from battle, and had succeeded to his wishes in describing every other mark that could indicate a mettlesome steed impatient of restraint; there was wanting nothing but a foam of a bloody hue issuing from the mouth. He again and again endeavoured to express this, but his attempts were unsuccessful. At last, in his vexation, he threw against the reins of the horse a sponge tinged with many colours; the mixture of which produced the very effect he had desired.

One of the chief excellencies of Apelles's pictures was their exact resemblance to the originals; but the quality of *grace* was claimed by him as his peculiar characteristic. His pencil was so famous for drawing fine lines, that Protogenes discovered by a single line that Apelles had been at his house. Protogenes lived at Rhodes: Apelles sailed thither, and went to his house with great eagerness to see the works of an artist who was known to him only by name. Protogenes was gone from home, but an old woman was left in charge of a large canvass, which was fitted in a frame for painting. She told Apelles that Protogenes was gone out; and asked him his name, that she might inform her master who had inquired for him. "Tell him," said Apelles, "he was inquired for by this person;" at the same time taking up a pencil, he drew on the canvass a line of great delicacy When Protogenes returned, the old woman acquainted him with what had happened. That artist, upon contemplating the fineness of the stroke, at once pronounced it to be the work of none other than Apelles; but drawing a still finer line of another colour within the first, he ordered the old woman to show that line to Apelles if he came again; and to say, "This is the person for whom you are inquiring." Apelles returned and saw the line: he would not for shame be overcome; and therefore, in a colour different from either of the former, he divided the line of Protogenes by a third so exquisitely delicate as to leave no space for the smallest touch of the pencil. Protogenes now confessed the superiority of Apelles, flew to the harbour in search of him, and resolved to leave the canvass with the lines on it for the astonishment of future artists. It was afterwards carried to Rome and preserved as a most wonderful work of art in the palace of the Cæsars.

Apelles was the first who made the works of Protogenes to be valued as they deserved among the Rhodians. He acknowledged that Protogenes was in some respects superior to himself; but that in one particular he himself excelled, viz., in knowing when to take his hand from the picture, an art which Protogenes had not yet learned, and therefore overworked his pieces. Apelles equally disapproved of too elaborate diligence, or too hasty negligence in execution. A studied work of Protogenes he esteemed less on the one account; and on the other, when a silly painter once brought him a picture, and said, "This I painted in a hurry," he replied, "Though you had not told me so, I perceived it was painted in haste; but I wonder you could not execute more such pieces in the same time."

It was customary with Apelles to expose to public view the works which he had finished, and to hide himself behind the picture, in order to hear the remarks of the passers by. He once overheard himself blamed by a shoemaker for a

fault in the shoes of one of his figures: on the following day the shoemaker, finding the fault corrected, began to animadvert on the leg; upon which Apelles with some anger looked out from behind the canvass, and bade him keep to his own province,—whence the proverb, "Ne sutor ultra crepidam."

The works of Apelles, of which a list is given by Pliny, were all admired; but the most celebrated were the picture of Alexander in the temple of Artemis at Ephesus, and that of Aphrodite emerging from the sea. Alexander was drawn with a thunder-bolt in his hand; and such was the effect produced by the *chiaro-scuro*, that the hand and the thunder-bolt seemed to start out from the canvass. This celebrated picture gave rise to the saying that there were two Alexanders; the one invincible, the son of Philip, the other inimitable, the offspring of Apelles. His Aphrodite Anadyomene, representing the goddess of beauty rising out of the sea, was esteemed the most exquisite figure which ever pencil had created.—(*Pliny*, xxxv. 36, § 10, 11, &c.)

APPELLICON, a native of Teos, who lived at Athens, and is chiefly remarkable for having collected a fine library, in which was then the only extant copy of the works of Aristotle. Sylla purchased this library, and brought it to Rome.—See *Plutarch*.

APELLITES, Christian heretics in the second century, who affirmed that Christ received a body from the four elements, which at his death he rendered back to the world, and so ascended into heaven without a body.

APENNINES, that extensive range of mountains traversing the entire extent of the Italian peninsula, and forming, as it were, the backbone of that country. They detach themselves from the maritime Alps, and pursue a general course, first in an easterly and afterwards in a south-south-easterly direction, till towards their extremity they divide to embrace the Gulf of Taranto. From the main chain numerous branches extend towards the Mediterranean and the Adriatic. This chain is inferior in beauty and grandeur to some of the other mountain ranges of Europe; being destitute of the glaciers and vertical needles of the Alps, the sharp peaks of the Pyrenees, or the rocky cliffs and escarpments of the Jura Mountains. Nowhere do they reach the snow line, though some of their summits are covered with snow during a great part of the year. Their mean height is about 4000, and their highest point, Monte Carno, or *Il gran sasso d'Italia*, the great rock of Italy, is 10,154 feet high; Monte Amaro, the highest point of Monte Majella, is 9131 feet high, and Monte Velino 8207 feet. The chain is little cultivated, and abounds with fine oaks and other kinds of trees; and the valleys are generally small and narrow. Almost all the rivers of Peninsular Italy take their rise in this range, but most of them are, with the exception of the Arno and the Tiber, little more than mountain torrents.

The name Apennines is probably of Celtic origin, and derived from *pen*, properly signifying the head, but also used for the summit of a mountain. By the Greek and Latin writers the name is generally used in the singular, as *Apenninus Mons*, Ὁ Ἀπέννινος, τὸ Ἀπέννινον ὄρος. The name may have been originally applied only to a particular mountain, and have afterwards been extended to include the whole chain.

The Apennines may be considered as a southern branch of the great Alpine system of Europe, and indeed there is no real separation between them; which has caused great differences of opinion among both ancient and modern geographers as to the point where the Alps terminate and the Apennines begin. Strabo, who gives a very accurate account of the general features and direction of this chain, considers it as beginning in the vicinity of Genoa, and in this he is nearly followed by many modern geographers who place its commencement between that town and Savona, in the valley of Bormida. The more natural commencement, however, seems to be at Col de Tenda, in Long. 7. 40. N. From Col de Tenda they run in a semicircle round the Gulf of Genoa in a general direction from west to east; they afterwards turn to the south and traverse the whole of the Italian peninsula to the Strait of Messina. The entire length of the chain is about 840 geographical miles, lying between Lat. 38. and 44. N. and Long. 7. 40. and 18. 20. E. They are divided into the Northern, Central, and Southern Apennines.

The *Northern Apennines* are separated from the Maritime Alps by the Tanaro and the Roya, which have their sources in Monte Cassino, and extend to Monte Coronaro. This division comprehends three subdivisions. The first, extending to Monte Bocchetta, proceeds first in an easterly direction, and afterwards, turning to the north-east, runs almost parallel to the western coast of the Gulf of Genoa, which it approaches so closely as to leave little more than a mere passage. The principal passes here, between Piedmont and the duchy of Genoa, are through the valleys of the Tanaro, the Bormida, and the Lemme. From Bocchetta the second subdivision extends in an eastern, and afterwards in a south-eastern direction to the mountain summit, under which the Reno rises. Its highest summits are the Lopotorlo, Gottro, and Jorame, in which rise the Trebbia, Taro, and Secchia, affluents of the Po. The chief passes are those of Boffaloro Cento-Croci, Pontremoli, Bratello, Fiumalbo, and Monte Carelli or Pietra-Mala. This subdivision forms the spacious bays of Rapallo and Spezzia, and its deep ravines and precipitous sides are characteristics which distinguish it from the rest of the chain. The third subdivision extends in a south-south-east direction to Monte Coronaro. The principal summits here are the Piano and the Falterona. The only pass worthy of notice is that proceeding from the valley of the Lieve, over Borgo di San Lorenzo, through the valley of the Lamore, and on towards Faenza.

The *Central Apennines* comprehend that part of the chain between Monte Coronaro, in which the Tiber rises, and Monte Velino, north of Lake Fucino. Its general direction is from north-north-west to south-south-east, and nearly parallel to the Tiber. The descent towards the Adriatic is continuous and direct, but towards the Mediterranean it forms two distinct inclined planes. The principal passes from the north are at the village of Scheggia, over a connecting ridge between Mounts Corno and Cucco, where the Cantiano, an affluent of the Metauro rises; at Seravalle, south-east of Monte Pennino, at the head of the valley of the Chienti, a small river flowing into the Adriatic; at Castellucio between Norcia and Arquate; and finally, the principal pass between Rieti and Aquila, to the east of Antrodoco.

The *Southern Apennines* include the remaining portion of this chain. From Monte Velino they proceed in a south-easterly direction to Acerenza in Basilicata, where they divide into two unequal branches, the eastern proceeding through the provinces of Bari and Otranto, and terminating at Cape Santa Maria di Leuca; the other, or western branch, running through Calabria to Cape dell' Armi on the Strait of Messina. In the upper part of the southern Apennines a number of sharp pyramidical points raise themselves above the mountain chain. Among these are Monte Forcone at the source of the Sangro, Monte Sant' Angelo, above the sources of the Volturno and Trigno, and Monte Calvello north-east of Salerno. The principal passes over this part of the Apennines are the pass of Sulmona, near the sources of the Volturno, so called from the town of Sulmona where the roads from Rome, Pescara, and Aquila

unite; the road going southwards by Pettorano, passing the upper Sangro, over Monte Janipro and the Iserina, and then dividing itself into two roads, the one southwards to Capua, the other eastwards by Campobasso towards Lucera and Foggia. The passes above Castel Franco and Ariano are the highest points of the road over the mountain ridge from Benevento to Troja, and from Avellino to Foggia. The eastern branch of the southern Apennines begins at the Lake of Pesole, and proceeds in an easterly, and afterwards in a southern direction to its termination at Cape Leuca. At Monte Albano it approaches very near the coast of the Adriatic. The best passages here are on the road from Taranto to Canosa, and from Ofanto and Bari to Ostani, Mesagna, and Lecca, which often contract into narrow defiles. The western branch extends in a southern direction from the Lake of Pesole to Capo dell' Armi. The principal passes here are in Calabria on the road from Naples to Sicily, and from Naples to Otranto passing by Taranto.

Connected with this main chain of the Apennines are three distinct groups of mountains, which usually take the distinguishing prefix of "Sub." These are the sub-Tuscan, the sub-Roman, and the sub-Vesuvian Apennines.

The *Sub-Tuscan Apennines* are a distinct group of mountains, extending over Tuscany. They are separated from the main range by the valleys of the Arno and Tiber, as well as by the Chiana, whence they diverge in the form of an obtuse angle towards the Mediterranean, covering with their ramifications all the country between the Arno and Po. On the top of the mountain range separating the Tiber from the Arno is the Lake of Perugia, which has no visible outlet. This range afterwards divides itself into several branches, between the two principal of which lies the district of the *Maremma* of Siena. The two principal passes here are those from Florence to Rome; the eastern going by Arezzo, thence above the Lake of Perugia to Foligno, &c.; the other from Siena over the two highest points of the two principal branches mentioned above, the one beyond Castiglioncello, the other on this side of Radicofani. From Siena there are also communications to Leghorn, Piombino, and Civita Vecchia.

The *Sub-Roman Apennines* detach themselves from the main chain near Monte Velino. They commence in the upper valleys of the Liri, Salto, Turano, and Sacco, where they contain the mountains of Cantaro, Corglio, Acuto, Carbonara, Ceraso, and Campatri, and afterwards lose themselves below the Lake of Albano. From the extremity a branch goes off almost in a straight line from Narni on the Nera to Sora on the Liri, and forms the valley of Velino. A second branch incloses the valley of the Anieno, the upper part of the Teverone, and divides the Liri from the Sacco. In the vicinity of Palestrina a third branch runs off between the Sacco and the Garegliano on the east, and the Pontine Marshes on the west, and terminates in a steep rocky tongue of land, on which the Fort of Gaeta stands. The extreme declivity forms the seven hills on which Rome is built. Over the main branch of this group there are three passes; the first, between the sources of the Liri and the Sacco, is the means of communication between Lora and Tagliacozzo, and hence it sends forth three branches to Aquila, Rieti, and Rome; the second extends from Zagarolo to Palestrina, on the direct route from Rome to Lora; the third passes above the lake, and is the great road from Rome to Naples by Terracina. Besides these there are other passes, as those from Rieti and Leonessa, the first proceeding to Viterbo and Rome, the other to Spoleto and Aquila; that from Celano to Carsoli on the road from Trivoli to Salmona; a by-way also goes from Carsoli in a north-western direction to Rieti through the valley of Turano.

The *Sub-Vesuvian Apennines* derive their name from the volcano Vesuvius which, with Somma, are the principal mountains of this group, and from which ramifications proceed in several directions. The only passage is that of Forchia or Claudina, near Monte Sarchio, north-east of Naples, and on the road to Benevento. See VESUVIUS.

The Apennines consist in part of white compact limestone containing no petrifactions or other heterogeneous substances. This rock does not, however, prevail through the whole range. From its junction with the Alps to Florence the chain is composed of calcareous or slaty masses, and of a serpentine rock called *gabbro* or *granitello*. This last principally composes the summits of the Mountains of Genoa rising from the Gulf of Spezzia. This part of the northern Apennines is generally considered to belong to the primitive formation, but some geologists contend that it belongs to the transition class with a large quantity of graywacke. The mountains extending from Florence to the Abruzzi and hence to Calabria, are composed of limestone analogous to that of the Jura range. In the last-mentioned province the central part of the chain is formed of granite, gneiss, and mica-schist, on which here and there repose some secondary deposits.

The Sub-Apennines belong to the tertiary formation, and are composed of marl, shale, gravel, sand, and conglomerate. Gypsum and calcareous and volcanic tufa are also seen here, but less frequently. Travertin, a limestone of recent formation, is found abundantly in the vicinity of Rome, and of it most of the edifices of that city are constructed. The volcanic mountains are all on the south-western side of the chain, with only one exception (Monte Voltore, near Melfi). The principal groups are those of Santa Fiora and Viterbo; that of Latium; those of Sant' Agatha and Rocca Monfina towards Sessa; and finally that of Naples. There is no active volcano except Vesuvius. Volcanic tufa forms a great part of the soil about Rome, and the Capitoline, Quirinal, Esquiline, Aventine, &c., are principally composed of it. Most of the lakes that surround Rome, as the Albano, Nemi, &c., occupy ancient craters. The environs of Modena abound in those small mud volcanoes called *Salzes*. They sometimes disengage carburetted hydrogen gas, and often this is inflamed, as may be seen at Villeia, Pietra Mala, and Barigazza. The Apennines contain few metals; the principal is iron, found in Tuscany, and particularly in the island of Elba. The coal mines are very unimportant, but there are extensive saliferous depôts near Cosenza. The marbles of the Apennines, however, are justly celebrated for their beauty, as those of Carrara, the ancient Luni, Seravazza, and Sienna.

APENRADE, a city in the duchy of Schleswig, the capital of the bailiwick of the same name. It contains 4200 inhabitants, chiefly occupied in agriculture, ship-building, and the transit trade. The harbour is shallow, and vessels must discharge below the town. The roadstead at the entrance is without shelter. Long. 9. 25. E. Lat. 55. 2. N.

APER, the wild boar. See *Sus Aper*, MAMMALIA.

APERIENT, a term applied to those medicines which act as deobstruents, and promote the secretions. See CATHARTICS.

APERTURE, in *Geometry*, the space between two right lines which meet in a point and form an angle.

APERTURE, in *Optics*, a round hole in a turned bit of wood or plate of tin, placed within the side of a telescope or microscope, near to the object glass, by means of which fewer rays are admitted, and a more distinct appearance of the object is obtained.

APETALOSE, or APETALOUS, among *Botanists*, an appellation given to such plants as have no flower-leaves.

APEX, the vertex or summit of any thing.

Apex, in *Antiquity*, the crest of a helmet, but more especially a kind of cap worn by the flamens.

Apex, among *Grammarians*, denotes the mark of a long syllable, falsely called a *long accent.*

APHÆRESIS (ἀπὸ and αἱρέω), a figure by which a letter or syllable is cut off from the beginning of a word. Thus *ciconia*, by aphæresis, is written *conia; contemnere, temnere; omittere, mittere,* &c.

APHEK, the name of several cities mentioned in Scripture. 1. A city in the tribe of Asher, supposed to be the same place with the Ἄφακα which Eusebius and Sozomen place in Lebanon, on the river Adonis, where there was a famous temple of Venus. A village called Afka is still found in Lebanon, situated at the bottom of a valley, and may possibly mark the site of this town. 2. A town near which Benhadad was defeated by the Israelites (1 Kings xx. 26, *sq.*); it seems to correspond to the Aphaca of Eusebius, situated to the east of the Sea of Galilee, and mentioned by Burckhardt, Seetzen, and others, under the name of Feik. 3. A city in the tribe of Issachar, not far from Jezreel, where the Philistines twice encamped before battles with the Israelites (1 Sam. iv. 1; xxix. 1). Either this or the first Aphek, but most probably this, was the *Aphek* mentioned in Josh. xii. 18, as a royal city of the Canaanites.

APHELIUM, or Aphelion (ἀπὸ from, and ἥλιος the sun), in *Astronomy*, is that point in any planet's orbit in which it is farthest distant from the sun, being that end of the greater axis of the elliptical orbit of the planet most remote from the focus where the sun is.

APHIOM, Karahissar. See Afium.

APHIS, the Puceron, Vine-fretter, or Plantlouse. See Entomology, *Index.*

APHLASTON, in Latin *Aplustre*, a wooden ornament, shaped like a plume of feathers, fastened on the goose's or swan's neck used by the ancient Greeks in the heads of their ships. The Aphlaston had much the same office and effect in a ship that the crest had on the helmet. It seems also to have had the further use of indicating the quarter of the wind by the waving of a party-coloured riband fastened to it.

APHLOGISTIC (α, priv., and φλόξ), or *Flameless Lamp.* This lamp is formed by winding a close coil of fine platinum wire loosely round the lower part of the wick of a spirit lamp. When the flame is extinguished, the coil will continue in a state of ignition till the spirit is consumed.

APHONIA (α, priv., and φωνή), a suppression or total loss of voice. It is never a primary disease, but a consequence of many different disorders. The cure is to be effected by removing the disorder from whence the aphonia proceeds.

APHORISM, a maxim or principle of a science, or a sentence which comprehends a great deal in a few words. The word comes from ἀφορίζω, *I separate.*

APHRACTI, in the *Ancient Military Art*, open vessels, without decks or hatches, furnished only at head and stern with cross planks, whereon the men stood to fight.

APHRODISIAS, the name given to several ancient cities in honour of Aphrodite.

APHRODITE, in *Grecian Mythology*, the goddess of love and beauty, one of the chief deities of Olympus. Homer calls her the daughter of Zeus, and the marine deity Dione. Hesiod derives her name from ἄφρος *foam*, as sprung from the foam of the sea. The Venus of the Romans had many of the attributes of Aphrodite; but there would seem to have been in the imagination of some of the ancients, a heavenly and an earthly Venus.

APHTHARTODOCETÆ, a name given to the followers of Julian of Halicarnassus, who taught, A.D. 519, that the body of Christ changed its nature and became incorruptible (ἄφθαρτος) from the moment of his conception, by the infusion of the divine nature. They were called also and Phantasiastæ, because their doctrine implied that the sufferings of Christ were not real but only seeming (δοκεῖν). This opinion was favoured by the Emperor Justinian, in whose reign it was agitated with great warmth.—(Mosheim, p. 237, Reid's edit.)

APHTHONG (from ἀπό φθόγγος), a letter or combination of letters, not sounded in the pronouncing of a word; as in a*l*mond, tong*ue*, apo*ph*the*g*m, *p*sa*l*m.

APHTHONIUS, *of Antioch*, lived about A.D. 315, and was the author of an elementary treatise on rhetoric (προγυμνάσματα), much read in the sixteenth and seventeenth centuries. He has also left about 40 Æsopic fables. The earliest edition of the *Progymnasmata* was contained in the *Aldine Rhetores Græci*, 1508. The best and latest edition, including all the annotations, is in the "Rhetores Græci" of Walz, Stuttg. and Tübing, 1832–35.

APHYLLOUS (α, priv., and φύλλον), in *Botany*, a term applied to plants which are leafless; such as the rush, mushroom, &c.

APIAN (properly *Bienewitz*), Peter, a distinguished astronomer, born in 1495, was professor of mathematics at Ingolstadt. His principal works are his *Cosmographia*, and his *Astronomicon Cæsareum;* the latter of which is remarkable as containing observations on the comet of 1531, subsequently known as *Halley's.* This work was illustrated with revolving paper planispheres. His son Philip was likewise a distinguished mathematician.

APIARY. Under the article Bee, in this work, directions will be given at considerable length as to the management of an apiary, and various methods detailed of procuring honey and wax from the hive without destroying the bees themselves. Greater attention to this useful appendage to the cottage would not only be productive of commercial advantage, but would tend to improve the condition of the lower order of peasantry. It is not generally known, indeed, what profitable returns may be obtained, at a trifling expense of time and labour, by very simple processes. Mr Huish, the author of a valuable practical treatise on the management of bees, has made a calculation, from which he infers, that even supposing the first cost of a swarm to be one guinea, which is the price in the places where they are sold the dearest, the cottager is almost certain, by proper care and management, of clearing, in five years, a net produce of nearly L.60, and of having besides, at the end of that period, ten good stocks of bees in his garden.

The principal objects to be attained in the construction and management of an apiary, are to secure the prosperity and multiplication of the colonies; to increase the amount of their productive labour; and to obtain their products with facility, and with the least possible detriment to the stock. The apiary should afford to the bees the best shelter against moisture and the extremes of heat and of cold, and especially against sudden vicissitudes of temperature; it should protect them against their numerous enemies; it should afford them every facility of constructing their combs, and of rearing their young; it should allow of every part of the combs being occasionally inspected, and being capable of removal when requisite; and, while due attention is paid to economy, it should be made of materials that will insure its durability. Much ingenuity has been displayed by different apiarians in the construction of hives which should unite in the greatest possible degree all these advantages. Although it be in vain to hope that every one of these objects can at once be perfectly attained, yet there is still great room for improvement on the hives that are at present in common use; and we shall here point out a few of the more recent modes of construction

Apiary.

While some cultivators of bees have been chiefly anxious to promote their multiplication, and to prevent the escape of the swarms in the natural way, by procuring what they have termed *artificial swarms*,—which they effected by separating a populous hive, previous to its swarming, into two parts, and allowing to each greater room for the extension of their works; others have contemplated only the abundance of the products which they yielded, and the facility of extracting them from the hive, without showing any particular solicitude as to the preservation of the bees themselves. Another class of apiarians have, on the other hand, had it more particularly in view to facilitate the prosecution of researches in the natural history and economy of bees. The hive invented by Mr Huber is peculiarly calculated for the last of these objects, and its construction is founded on an accurate knowledge of the habits of these insects. He has given it the name of *ruche en livre ou en feuillets*, from its opening and shutting somewhat in the manner of the leaves of a book. This *book* or *leaf hive* is composed of from eight to twelve square wooden frames, placed vertically, and joined together sidewise like the hoops of a cask. Each frame consists of two uprights, one inch in thickness, a foot in height, and an inch and a third in width, connected by an upper and lower cross bar, ten inches long, and of the same breadth and thickness as the former; so that all the frames may be joined together, without leaving any interval. The two external frames are closed each by a pane of glass, which is covered by a shutter on the outside; and the whole is properly secured in its place, and further protected by an external cover. An aperture must of course be left in the lower part of one of the frames to serve as a door. In order to determine the bees to construct their combs in the plane of each leaf, a small piece of honeycomb is fixed, by means of pegs, to the top of each in the proper position, as it is well known that bees always complete their work in the direction in which they find it begun, unless they meet with some insurmountable obstacle. A proper distance is thus preserved between the lateral surfaces of the perpendicular combs; and the external ones, being only three or four lines distant from the glass panes, may be easily inspected by opening the shutters; and also by opening in succession the different divisions of the hive, both surfaces of every comb may at pleasure be fully brought into view. No difficulty is experienced in introducing swarms into hives of this construction; and after the lapse of a few days, when the colony is fully established, the bees will very patiently submit to be daily inspected.

Mr Huber's hive.

Mr Huber's hive is exceedingly well calculated for producing artificial swarms on the principle of Schirach's discovery, of which a full account will be given in the article Bee. It allows us to judge by inspection whether the population is sufficient to admit of division,—if the brood is of the proper age,—and if males exist, or are ready to be produced, for impregnating the young queen; all which circumstances are of material consequence to the success of the operation. It is essential that some of the larvæ should not have been hatched above three days before this attempt is made. The frames must then be gently separated at the middle of the hive, and two empty frames be introduced in the interval between the former; each of these new frames having a partition which closes them completely, so as to enable the two portions to be entirely separated without leaving any opening. The door of that portion in which the queen happens to be at this time may remain open, but the one belonging to the other part must be closed, so as to retain the bees that have no queen prisoners for 24 hours, allowing still, however, sufficient circulation of air. After this interval of time they appear to have forgotten their queen, at least they are no longer anxious to seek for her, but bestow all their solicitude in the education of the larvæ, so as to convert a certain number of them into queens to supply the loss they have sustained. This they accomplish in ten days or a fortnight after the operation. The two colonies are now perfectly distinct, and are never found afterwards to intermix.

Another advantage attending a hive of this construction consists in its enabling us to force the bees to produce a much greater quantity of wax than they would naturally do. The interval which separates the combs when the bees have not been disturbed in their operations is constantly the same, namely, about four lines. Were they too distant, it is evident that the bees would be much dispersed, and unable to communicate their heat reciprocally, and the brood would not be preserved in a sufficient degree of warmth. Were the combs too close, on the contrary, the bees could not freely traverse the intervals, and the work of the hive would suffer. It is evident that we may avail ourselves of this instinct, and, by separating farther asunder the combs that are already built, induce the bees either to extend the breadth of those they had begun, or to build others in the interval, if sufficient space be allowed them for this purpose. Thus, by interposing three empty frames, one between every alternate interval of the combs in a hive containing six combs, three additional combs, if the proper season be chosen, will be obtained at the end of a week; and if the weather continue favourable, the operation may be repeated, and the same number of additional combs procured the week after.

The principal obstacles to the general employment of Mr Huber's hives are the expense of constructing them, and the greater degree of attention which they perhaps require from the cultivator. It has also been objected that the flatness of the roof was prejudicial, by allowing the moisture which exhales from the bees to collect at the top, and to fall in drops at different parts, to the great injury of the subjacent contents of the hive. Feburier proposes therefore the employment of frames in the form of a trapezium, so that the roof shall be considerably inclined to the horizon. He borrows this shape from Bosc, whose hive consists, however, only of two boxes joined together sidewise, and separable in order to form artificial swarms. This was an improvement upon Gelieu's hive, which was formed of two square boxes united laterally. Delator had recommended a still more simple form than that of Bosc, though less convenient; namely, that of a triangle resting on its base. Mr Ravenel's hive consists of three square boxes instead of two; Mr Scrain's is also made up of three boxes, but they are low and of great length, and are joined endwise,—a communication being established between them by apertures made in the divisions which separate the boxes. It is now, however, well established, that partitions of any kind are detrimental to the prosperity of the colony. The same objection applies, though perhaps in an inferior degree, to the system of storied hives, or those which are divided into stories one above another. A great variety of the latter description, however, have been recommended by different cultivators. In France they are known by the name of *ruches en hausses*. Mr Thorley's improved hive is of this class, and Mr Lombard's *ruche villageoise* may also be referred to the same head, although it be of much simpler construction than any other compound hive. Mr Lombard's hive is composed of two parts, a body and a cover, forming together an elevation of from seventeen to twenty inches, on a uniform diameter of one foot, excepting the upper part, which ought to be convex. The body is formed of bands of straw, similar to that of the cottages in this country,

Hives of other apiarians.

At the top and bottom of the body is placed an exterior band, which forms a projecting border on each end, the lower one giving the hive a firm station on its pedestal, the upper one contributing to secure the attachment of the cover, or allowing of another similar body being placed above the first, if such an addition should be deemed necessary. At the top of the body, and even with the upper band, is placed a flooring board, made of a light plank, ten inches in breadth in all directions, and the four corners of which are sawed off in such a manner that the breadth along the diagonal measures one foot. This board is fixed by nails inserted in the upper double band, and entering a little into the front. The four openings that are left on the sides are necessary for the passage of the bees, and for the escape of the vapours which are exhaled from them in winter. A flat rod traverses the hive immediately under the board, and projecting from the two sides about an inch and a half, affords handles for lifting the hive, and facilitates the fastening of the cover, which has also a projecting rod corresponding with that of the hive. At the bottom is an opening two inches broad and nine lines in height for the ingress and egress of the bees. The cover is formed in the shape of a dome, with a vertical handle at the top, and a cross bar at the lower part, by the projecting ends of which it may be tied to the ends of the bar in the body, and which serves also as a support to the combs that are constructed in the cover. For the latter purpose, also, two other bars are placed crosswise, one above the other. All the hives and all the bases of the covers are to be made of one uniform diameter, in order that the hives may, if occasion require it, be placed upon each other, and the covers be adapted to any of the hives that may happen to be at the top.

The *pyramidal hive* of M. Ducouédie, which the inventor extols in his book entitled *La Ruche Pyramidale, avec l'art d'établir et d'utiliser les ruches*, &c. as leaving nothing more to be wished for as to the cultivation of bees, differs but little from that of Mr Thorley. A common straw hive is taken, containing a swarm, which is allowed to remain till the spring of the following year; it is then placed on the top of a square box, with which it is made to communicate by a round aperture at the top of the box. In this state it is termed by the French *la ruche Ecossaise*, or, *ruche de M. de la Bourdonnaye.* In the following spring a second box is placed under the first, and the whole now assumes the name of *la ruche pyramidale.* The bees are still allowed no other ingress or egress but by a single hole made in the lowest story. The upper stories may then be removed in succession, while further room is allowed below by the addition of fresh boxes. It is stated by M. Ducouédie, that the bees in his pyramidal hive never perish by hunger or by cold; for they always abound in provisions, and are too numerous to be affected by the most rigorous winter. When the bees are in groups, they maintain the necessary warmth in the hive, and the brood, on the return of spring, is hatched one month sooner than in any other hive. Mr Huish has, however, made it clearly appear that these pretended advantages are much exaggerated, while its inconveniences are passed over in silence. It is difficult, if not impossible, to proportion the hives in all cases to the magnitude of the swarms, or to the energy with which they labour. The honey being taken from the oldest cells, is deteriorated by an admixture of pollen, communicating to it a degree of bitterness, of which it is difficult to deprive it; and it is less abundant, in consequence of the diminished capacity of the cells, in which the coccoons of successive bees in their state of nympha have accumulated. From their being divided into different stories, the bees are obliged to live, as it were, in different families; while their own preservation and that of the brood requires them to live in the strictest union. The heat is also lessened by the division of the bees into different groups. The upper part of these hives being all necessarily flat (except the first or straw hive), occasions a serious inconvenience, by allowing moisture to collect and drop down into the middle of the hive, instead of trickling down the sides. The injury which this does to the combs, and to the bees themselves, who are constantly exposed to its influence, is, according to Mr Huish, the most common cause of the loss of the hives during the winter. The bees, he observes, always begin their work in the most elevated point of the hive, and seek for that purpose the central part of the roof. If the top be flat, and especially if it be as spacious as in the hives called pyramidal, the bees will not find this centre; they will work one year in one part, and the following year in another. This is without doubt one of the causes which oblige a proprietor to wait three or four years before any honey can be gathered from these hives.

The hive recommended by Mr Huish as affording sufficient facility for examining any of the combs, and performing on them any operation at pleasure, is very similar in form to that described as being used in Greece. The body of the hive is a straw basket in the shape of a flower-pot, that is, of a broader diameter above than below. Eight pieces of well-seasoned wood, about eight inches broad and half an inch thick, are laid parallel to one another, at equal distances, over the top of the basket, and fastened to an outer projecting band: they are then covered with network, over which is placed a circular board, or what is better, a convex cover of straw extending over the whole of the top of the hive. This network obliges the bees to fasten their combs to the transverse boards, by means of which each comb can easily be lifted up without interfering with any other part of the hive, or occasioning the loss of a single bee; and the whole of the interior of the hive is thus open to inspection, and we are enabled to trace the devastations of the moth, or to ascertain the presence of any other enemy.—See the article Bee. (P. M. R.)

APICIUS. There were at Rome three persons of that name, all celebrated as epicures. The second, M. Gabius Apicius, is the most famous of the three. He lived under Tiberius, and invented various sorts of cakes and sauces which bore his name. He squandered L.800,000 on his luxurious appetite; and finding his fortune reduced to little more than L.80,000, he grew alarmed at the prospect of starvation, and poisoned himself. His last draught, according to Seneca, was the most commendable he had ever swallowed. His name was long venerated by the votaries of the gastronomic art, as the highest of culinary authorities; and rival schools of cookery claimed their descent from the great Apicius. A treatise, *De Re Culinaria, sive de Obsoniis*, &c., by an unknown writer under the assumed name of Cælius Apicius has been frequently reprinted. The best edition is that of Lister, Lond., 1705, 8vo.

APINGADAM, or Appingadam, a town of Holland, in the province of Groningen, and capital of the circle of the same name. Pop. 3600.

APION, a famous grammarian and commentator upon the Homeric poems, born at Oasis in the land of Apis, though he called himself an Alexandrian. He flourished A.D. 30, and was conspicuous for his opposition to the Jews. Some fragments of his writings are extant, including the story of Androclus and the Lion, preserved in Aulus Gellius; and his treatise against the Jews, preserved with the works of Josephus, who wrote a reply to it.

APIS, a divinity worshipped by the ancient Egyptians at Memphis under the form of an ox, having certain exterior marks. The soul of Osiris was supposed to subsist in

the body of this animal. "A white spot," says Pliny, "resembling a crescent, on the right side, and a lump under the tongue, were the distinguishing marks of Apis." When a cow, therefore, which was thought to be struck with the rays of the moon, produced a calf, the sacred guides went to examine it, and if they found it conformable to this description, they announced to the people the birth of Apis.

"Immediately," says Ælian, "they built a temple to the new god, facing the rising sun, according to the precepts of Hermes, where they nourished him with milk for four months. At the expiration of this term, the priests repaired in pomp to his habitation, and saluted him by the name of Apis. They then placed him in a vessel magnificently decorated, covered with rich tapestry, and resplendent with gold, and conducted him to Nilopolis, singing hymns and burning perfumes. There they kept him for forty days. During this space of time women alone had permission to see him, and saluted him in a particular manner. After the inauguration of the god in this city, he was conveyed to Memphis with the same retinue, followed by an innumerable quantity of boats sumptuously decked out. There they completed the ceremonies of his inauguration, and he became sacred to all the world. Apis was superbly lodged, and the place where he lay was mystically called *the bed*."

There was a mysterious term fixed for his life. "Apis," says Pliny, "cannot live beyond a certain number of years. When he has attained that period they drown him in the fountain of the priests; for it is not permitted to let him prolong his life beyond the period prescribed for him by the sacred books." When this event happened he was embalmed, and privately let down into the subterraneous place destined for that purpose, after which the priests announced that he had disappeared; but when he died a natural death before this period arrived, they proclaimed his death, and solemnly conveyed his body to the temple of Serapis. Huet, bishop of Avranches, has endeavoured to prove that Apis was a symbolical image of the patriarch Joseph, and has supported his opinion with all his erudition. Mr Bryant apprehends that the name *Apis* was an Egyptian term for father; that it referred to the patriarch Noah; and that the crescent which was usually marked on the side of the animal was a representation of the ark.

APIUM, a genus of *Umbelliferæ*, of which the best known is *A. graveolens*, celery.

APO (*Greek* ἀπό), a prefix to many words, signifying *from*. It corresponds to the Latin *ab*, and the English *off*.

APOCALYPSE, Revelation, the name of one of the sacred books of the New Testament, containing revelations concerning several important doctrines of Christianity. The word is Greek, and derived from ἀποκαλύπτω, *I reveal* or *discover*.

This book, according to Irenæus, was written about the year 96 of Christ, in the island of Patmos, whither St John had been banished by the Emperor Domitian. But Sir Isaac Newton places the writing of it earlier, viz., in the time of Nero. Some attribute this book to the arch-heretic Cerinthus; but the ancients unanimously ascribed it to John, the son of Zebedee, and brother of James, whom the Greek fathers called the *Divine*, by way of eminence, to distinguish him from the other evangelists. This book has not at all times been esteemed canonical. There were many churches in Greece, as St Jerome informs us, which did not receive it; neither is it in the catalogue of canonical books prepared by the council of Laodicea, nor in that of St Cyril of Jerusalem: but Justin, Irenæus, Origen, Cyprian, Clemens of Alexandria, Tertullian, and all the fathers of the fourth, fifth, and the following centuries, quote the Revelation as a book then acknowledged to be canonical. The Alogians, Marcionites, Cerdonians, and Luther himself, rejected this book; but the Protestants have forsaken Luther in this particular; and Beza has strongly maintained, against his objections, that the Apocalypse is authentic and canonical.

There have been several other works published under the title of *Apocalypse*. Sozomen mentions a book used in the churches of Palestine, called the *Apocalypse* or *Revelation of St Peter*. He also mentions an Apocalypse of St Paul, which the Copts retain to this day. Eusebius also speaks of both these Apocalypses. St Epiphanius mentions an Apocalypse of Adam; Nicephorus, an Apocalypse of Esdras; Gratian and Cedrenus, an Apocalypse of Moses, another of St Thomas, and another of St Stephen; St Jerome, an Apocalypse of Elias. Porphyry, in his life of Plotinus, makes mention of the Apocalypse or Revelations of Zoroaster, Zostrian, Nicothæus, Allogenes, &c.

APOCOPE (ἀπό and κόπτω), among *Grammarians*, a figure which cuts off a letter or syllable from the end of a word; as *ingeni* for *ingenii*.

APOCRISARIUS (ἀπόκρισις an answer), in *Ecclesiastical History*, a sort of resident in an imperial city, in the name of a foreign church or bishop, whose office was to negotiate, as proctor at the emperor's court, in all ecclesiastical causes in which his principals might be concerned. The institution of the office seems to have taken place in the time of Constantine, or not long after, when, the emperors having become Christians, foreign churches had more occasion to promote their suits at court than formerly. We find it, however, established by law in the time of Justinian. In imitation of this officer, almost every monastery had its Apocrisarius, or resident in the imperial city. The title and quality of apocrisary became at length appropriated to the pope's agent, or *nuncio*, as he is now called, who resided at Constantinople to receive the pope's despatches and the emperor's answers.

APOCRUSTICS, in *Medicine*, the same as repellents.

APOCRYPHA (ἀπόκρυφα, sc. βιβλία, *hidden, secreted, mysterious*), a term in *Theology*, applied in various senses to denote certain books claiming a sacred character. It is first found in this use in Clemens Alexandrinus, *Stromata*, 13, c. 4, ἐκ τινὸς ἀποκρύφων.

In the early ages of the Christian Church this term was frequently used to denote books of an uncertain or anonymous author, or of one who had written under an assumed name. Its application, however, in this sense is far from being distinct, as, strictly speaking, it would include *canonical* books whose authors were unknown or uncertain, or even *pseudepigraphal*.

In the *Bibliothèque Sacrée*, by the Rev. Dominican Fathers Richard and Giraud (Paris, 1822), the term is defined to signify—1*st*, anonymous or pseudepigraphal books; 2*d*, those which are not publicly read, although they may be read with edification in private; 3*d*, those which do not pass for authentic and of divine authority, although they pass for being composed by a sacred author or an apostle, as the *Epistle of Barnabas;* and, 4*th*, dangerous books composed by ancient heretics to favour their opinions. They also apply the name "to books which, after having been contested, are put into the canon by consent of the churches, as Tobit," &c. And Jahn applies it in its most strict sense, and that which it has borne since the fourth century, to books which, from their inscription, or the author's name, or the subject, might easily be taken for inspired books, but are not so in reality. It has also been applied, by Jerome, to certain books not found in the Hebrew canon, but yet publicly read from time immemorial in the Christian church for edification, although not considered of authority in controversies of faith. These were also termed Ecclesiastical Books, and consisted of the Books of Tobit, Wisdom, Ecclesiasticus, Baruch, the first two Books of Maccabees, the last seven chapters (according to Cardinal Hugo's division) of the Book of Esther, and those (so called) parts of the

Book of Daniel which are not found in Hebrew, viz., the Song of the Children, the Speech of Azariah, the History of Susannah, and the Fable (as Jerome calls it) of Bel and the Dragon. These have been denominated, for distinction's sake, the deutero-canonical books, inasmuch as they were not in the original or Hebrew canon. In this sense they are called by some the Antilegomena of the Old Testament. "The uncanonical books," says Athanasius, or the author of the *Synopsis*, "are divided into *antilegomena* and *apocrypha*."

Among spurious and Apocryphal Books, as distinct from Antilegomena or Ecclesiastical, are doubtless to be considered the Third and Fourth Books of Esdras; the Book of Enoch; the Testament of the Twelve Patriarchs: the Assumption of Moses, &c. These books were all known to the ancient fathers; and, although incontestably spurious, are of considerable value from their antiquity, as throwing light upon the religious and theological opinions of the first centuries. The most curious are the Third and Fourth Books of Esdras, and the Book of Enoch, which has been but recently discovered, and has acquired peculiar interest from its containing the passage cited by the apostle Jude.

Most of the apocryphal Gospels and Acts noticed by the fathers, and condemned in the catalogue of Gelasius, are generally thought to have been the fictions of heretics in the second century, and have long since fallen into oblivion. Of those which remain, although some have been considered by learned men as genuine works of the apostolic age, the greater part are universally rejected as spurious, and as written in the second and third centuries. A few are, with great appearance of probability, assigned to Leucius Clarinus, supposed to be the same with Leontius and Seleucus, who was notorious for similar forgeries at the end of the third century. The authorship of the *Epistle of Barnabas* is still a matter of dispute; and there appear strong grounds for believing the charge made by Celsus against the early Christians, that they had interpolated or forged the ancient Sibylline Oracles.

But, whatever authority is to be ascribed to these documents, it cannot be denied that the early church evinced a high degree of discrimination in the difficult task of distinguishing the genuine from the spurious books. "It is not so easy a matter," says the learned Jeremiah Jones, "as is commonly imagined, rightly to settle the canon of the New Testament. For my own part, I declare, with many learned men, that in the whole compass of learning I know no question involved with more intricacies and perplexing difficulties than this." (*New and Full Method*, vol. i. p. 15.)

Testimony and tradition are the principal means of ascertaining whether a book be canonical or apocryphal. Inquiries of this kind, however, must of necessity be confined to the few. The mass of Christians, who have neither time nor other means of satisfying themselves, must confide, in questions of this kind, either in the judgment of the learned, or the testimony at least, if not the authority, of the church.

The following are the principal apocryphal (or spurious) books of the Old Testament, which have descended to our times. The greater number of them can scarcely be considered as properly belonging to the Apocrypha of the Old Testament, as they have been most probably written since the Christian era, and not before the second century:—Third and Fourth Esdras, the Book of Enoch, the apocryphal Book of Elias the Prophet, the Third, Fourth, and Fifth Books of Maccabees (received by the Greek Church), the Ascension of Isaiah, the Assumption of Moses.

Of the New Testament, the following are the extant spurious Gospels:—The History of Joseph the Carpenter, which has been preserved in the East in an Arabic translation. The Gospel of the Infancy; the Gospel of Thomas the Israelite; the Protevangelion of James; the Gospel of the Nativity of Mary; the Gospel of Nicodemus, or Acts of Pilate. Besides these, many are cited by the fathers which no longer exist.

Of spurious writings of the nature of Acts of Apostles the following are extant:—The Creed of the Apostles; the Recognitions of Clement, or the Travels of Peter; the Shepherd of Hermas; the Acts of Paul, or the Martyrdom of Thecla; Abdias' History of the Twelve Apostles; the Constitutions of the Apostles; the Canons of the Apostles; the Liturgies of the Apostles. Of spurious Epistles,—The Epistles of Barnabas, Clement, Ignatius, and Polycarp; the Epistle of Paul to the Laodiceans; the Third Epistle of Paul to the Corinthians; the Epistle of Peter to James; the Epistles of Paul and Seneca.

Besides these many other pretended sacred writings were palmed upon the world, of which the titles alone are preserved, and probably many more of which the very names have perished. See Fabricii *Codex Pseudepigraphus V. T.*, 1713 and 1741, and *Codex Apocryphus N. T.*, 1713–1722; *Auctarium Codicis Apocryphi N. T. Fabriciani*, edidit And. Birch, 1804. *A New and Full Method of Settling the Canon of the N. T.*, by the Rev. Jeremiah Jones, 1827. Du Pin, *Prolegomena*, 1701, and *Canon of the Old and New Testaments*, 1700; and *Codex Apocryphus N. T.*, *opera et studio* T.C. Thilo, tom. i., Lips. 1832, 8vo.

APOCYNEÆ, a natural order of dicotyledonous plants. It includes many deadly poisons, as *Strychnos nux vomica*, *S. toxicaria*, *cerbora*, *&c.*

APODECTÆ (ἀποδέκται), in *Antiquity*, a denomination given to ten general receivers appointed by the Athenians, to receive the public revenues, taxes, debts, and the like. The apodectæ had also a power to decide all controversies arising in relation to money and taxes, except those of the most difficult nature and highest concern, which were reserved to the courts of judicature.

APODICTIC (ἀπόδειξις, a demonstration), a philosophical term originating with Aristotle, and introduced into modern usage by Kant, who applies it to those judgments that are beyond all contradiction, as distinguished from such as are merely empirical.

APODYTERIA (from ἀποδύομαι), in the ancient baths, the apartments for dressing and undressing.

APOGEE (ἀπὸ and γῆ), in *Astronomy*, that point in the orbit of a planet which is at the greatest distance from the earth. The apogee of the sun is that part of the earth's orbit which is at the greatest distance from the sun; and, consequently, the sun's apogee and the earth's aphelion are one and the same point.

APOKERUXIS (ἀποκήρυξις), was a legal process at Athens, by which a father could cast off and disinherit his son for deficiency in filial duty, riotous living, and the like, with power to reinstate him at pleasure.

APOLLINARIAN GAMES (*Ludi Apollinares*), in *Roman Antiquity*, were instituted in the year B.C. 212, after the fatal battle at Cannæ. The occasion was a kind of oracle delivered by the ancient prophet Marcius, declaring that, to expel the enemy, and cure the people of an infectious disease which then prevailed, sacred games were to be annually performed in honour of Apollo; the prætor to have the direction of them, and the decemviri to offer sacrifices after the Grecian rite. For some time they were moveable or indictive, but at length were fixed, under P. Licinius Varus, to the 6th of July, and made perpetual. The Apollinarian games were merely scenical, and at first only observed with singing, piping, and other sorts of music; but afterwards there were also introduced all manner of mountebank tricks, dances, and the like; yet they still remained scenical, no chariot races, wrestling, or laborious exercises of the body, being ever practised at them.

APOLLINARIANS, APOLLINARISTS, called also by

Epiphanius, *Dimæritæ*, ancient heretics who denied the proper humanity of Christ, and maintained that the body which he assumed was endowed with a sensitive, and not a rational soul, but that the Divine nature supplied the place of the intellectual principle in man. This sect derived its name from Apollinaris, bishop of Laodicea in the fourth century.

APOLLINARIS, SULPICIUS, a very learned grammarian, born at Carthage, lived in the second century under the Antonines. He is supposed to be the author of the verses which are prefixed to the comedies of Terence, and which contain the arguments of them. He had for his pupil Helvius Pertinax, who afterwards became emperor.

APOLLINARIS SIDONIUS, *Caius Sollius*, an eminent Christian writer and bishop in the fifth century, was born of a noble family in France. He was educated under the best masters, and made great progress in the several arts and sciences, but particularly in poetry and polite literature. He married Papianilla, the daughter of Avitus, who was consul, and afterwards emperor, by whom he had three children. But Majorianus, in the year 457, having deprived Avitus of the empire, and taken the city of Lyons, in which our author resided, Apollinaris fell into the hands of the enemy. The reputation of his learning softened Majorianus's resentment, so that he treated him with the utmost civility; in return for which Apollinaris composed a panegyric in his honour, which was so highly applauded, that he had a statue erected to him at Rome, and was honoured with the title of *Count*. In the year 467 the Emperor Anthemius rewarded him for the panegyric which he had written in honour of him, by raising him to the post of governor of Rome, and afterwards to the dignity of a patrician and senator. But he soon quitted these secular employments for the service of the church. The bishopric of Clermont being vacant in 472 by the death of Eparchius, Apollinaris, who was then only a layman, was chosen to succeed him. Clermont being besieged by the Goths, he animated the people to the defence of that city, and would never consent to a surrender; so that when it was taken, about the year 480, he was obliged to retire. He was soon, however, restored by Evaric, king of the Goths, and continued to govern the church as before. He died on the 21st of August 482. He is esteemed one of the most acute and vigorous writers of his age, both in prose and verse. His chief works are his *Panegyrics* upon the Emperors Avitus, Majorianus, and Anthemius, and a collection of *Letters* and *Poems*. The best edition of these productions is that by Sirmond, published in 1614, and republished by Labbé in 1652, in 4to. There is a French translation of his *Letters*.

APOLLO, in *Mythology*, a pagan deity worshipped by the Greeks and Romans, who was originally the god of the sun, and as such, synonymous with Ἥλιος or *Sol*.

Apollo had a variety of other names, derived from his principal attributes, or the chief places where he was worshipped. He was called the *Healer* (*Akestor*), from his enlivening warmth and cheering influence; *Nomius*, or the shepherd, from his fertilizing the earth, and thence sustaining the animal creation; *Delius*, from his rendering all things manifest; *Pythius*, from his victory over Python; *Lycius*, *Phœbus*, and *Phaneta*, from his purity and splendour. As Apollo is almost always identified by the Greeks with the sun, it is no wonder that he should have been dignified with so many attributes. It was natural for the most glorious object in nature, whose influence is felt and seen by every animated part of creation, to be adored as the fountain of light, heat, and life. The power of healing diseases being chiefly given by the ancients to medicinal plants and vegetable productions, it was natural to exalt into a divinity the visible cause of their growth. Hence he was also styled the *God of Physic*; and that external heat which cheers and invigorates all nature, being transferred from the human body to the mind, gave rise to the idea of all mental effervescence coming from this god; hence likewise, poets, prophets, and musicians, are said to be *Numine afflati*, inspired by Apollo.

Vossius has taken great pains to prove this god to be only a metaphorical being, and that there never was any other Apollo than the sun. "He was styled the *Son of Jupiter*," says this author, "because that god was reckoned by the ancients the author of the world. His mother was called *Leto* or *Latona*, a name which signifies *hidden*, because, before the sun was created, all things were wrapped up in the obscurity of chaos. He is always represented as beardless and youthful, because the sun never grows old or decays; and what else can his bows and arrows imply but his piercing beams?" And he adds, that all the ceremonies which were performed to his honour had a manifest relation to the great source of light which he represented.

Of the four Apollos mentioned by Cicero, it appears that the last three were Greeks, and the first an Egyptian, who, according to Herodotus, was the son of Osiris and Isis, and called *Orus*. Pausanias is of the same opinion as Herodotus, and ranks Apollo among the Egyptian divinities. The testimony of Diodorus Siculus is still more express; for in speaking of Isis, after saying that she had invented the practice of physic, he adds, that she taught this art to her son Orus, named *Apollo*, who was the last of the gods that reigned in Egypt.

To the other perfections of this divinity the poets have added beauty, grace, and the art of captivating the ear and the heart, no less by the sweetness of his eloquence, than by the melodious sounds of his lyre. One of the chief functions of this divinity was that of revealing the future to man, whence he was the great oracular divinity among the ancients.

The defeat of the serpent Python formed a celebrated incident in the history of Apollo. The waters of Deucalion's deluge, says Ovid, which had overflowed the earth, left a slime, from whence sprung innumerable monsters; and among others the serpent Python, which made great havock in the country about Parnassus. Apollo, armed with his darts, put him to death; which, physically explained, implies that the heat of the sun having dissipated the noxious steams, these monsters soon disappeared.

This event gave rise to the institution of the Pythian games, so frequently mentioned in the Grecian history; and it was from the legend of Apollo's victory over the Python that the god himself acquired the name of *Pythius*, and his priestess that of *Pythia*. The city of Delphi, where the famous oracles were so long delivered, was frequently styled *Pytho*.

APOLLO BELVEDERE, a representation of Apollo, generally ranked as the masterpiece of ancient statuary. It was so called from having been placed in the Belvedere of the Vatican by Pope Julius II., where it remained till 1797, when Rome was taken and plundered by the French. It was again restored after the peace of 1815.

This celebrated statue was found in the ruins of ancient Antium, now *Capo d'Anzo*, about the end of the fifteenth century. The artist and the epoch of its execution are unknown. It has been supposed to agree with the description of Pliny, *Hist. Nat.* xxxvi. 4, 10, and has been attributed by some to Calamis, by others to Phyliscus, and by others again to Praxiteles. The first was the opinion of Visconti (see Feuerbach's learned work, *Der Vaticanische Apollo*, Nuremb. 1833, 8vo). But according to the most probable opinion, this statue is sculptured in the Italian marble of Luni, and was executed about the time of Nero. See Tiersch, *Epochen*, &c. The hands and right arm which were wanting in the original, were restored by Angelo da Montorsoli, a pupil of Michael Angelo.

This wonderful work of art represents the highest ideal of manly beauty. "The lord of the unerring bow" has just discharged his arrow at the serpent Python. His cloak, his sole covering, lightly fastened round his neck, is flung over his left shoulder, and hangs gracefully from his outstretched arm, which grasps the still quivering bow. His face expresses the calm and proud triumph of a god, who needs but the putting forth of his hand to ensure him victory. "As the skilful artist," says Winckelmann, "wished to personify the most beautiful of the gods, he expressed only the anger in the nose—this organ, according to the old poets, being its appropriate seat—and the contempt on the lips. The latter emotion is manifested by the elevation of the lower lip, by which the chin is raised at the same time; the former is visible in the dilated nostrils." (*Hist. of Anc. Art among the Greeks*, p. 159, English translation. Lond. 1850.) The open right hand rests on the stump of a tree, around which winds a serpent, at once emblematic of the healing power of the god, and suggestive of the object of his victory.

APOLLODORUS, a celebrated painter of Athens about 408 years before the birth of Christ, was the first who invented the art of mingling colours, and of expressing lights and shades, on which latter account he received the name of Σκιαγράφος. He was admired also for his judicious choice of subjects, and for beauty and strength of colouring surpassed all the masters that went before him.

There was also a sculptor of this name who flourished about the same period, and made statues in bronze. He was surnamed the *Mad*, from his practice of breaking his works in pieces when they did not realize his idea.

Apollodorus *of Carystus*, a Greek comic poet, about 300 years B.C., was a native of Eubœa. He wrote, according to Suidas, 47 comedies, and gained the prize five times. His plays were composed at Alexandria, where they were greatly in esteem. The *Hecyra* and *Phormio* of Terence are said to have been imitated from this writer.—Meineke, *Hist. Crit. Comic. Græc.*

Apollodorus, tyrant of Cassandria, subverted the liberty of his country, B.C. 279, after having deceived the people by an appearance of ardent attachment to their rights. He was dethroned and put to death by Antigonus Gonatas.

Apollodorus *of Gela*, a Sicilian comic poet, said to have been a contemporary of Menander, and frequently confounded with Apollodorus of Carystus. Some fragments of his plays are given in Meineke's *History*.

Apollodorus *the Athenian*, a famous grammarian, the son of Asclepiades and disciple of Aristarchus. He wrote many works not now extant; but his most famous production is his *Bibliotheca*, which treats of the gods and the heroic ages. It is supposed by some that this is only an abridgment by another hand, and not the original work of Apollodorus. In any view it is, however, of great value in mythological inquiries. The best edition is that of Heyne, in 4 vols. 8vo, published in 1803. A French translation, with notes, was published at Paris in 1805, in 2 vols. 8vo.

Apollodorus *of Pergamus*, a Greek rhetorician, who founded a school called after his name. He taught at Rome and at Apollonia, and had Octavianus, afterwards Augustus, as his pupil.

Apollodorus, an epigrammatic poet, supposed to have been a native of Smyrna. He lived under Augustus and Tiberius. Thirty of his epigrams are preserved in the Greek Anthology.

Apollodorus, a famous architect under Trajan and Hadrian, was born at Damascus. Among his principal works were the Forum of Trajan, the Odeum, and various other public buildings at Rome; the triumphal arches at Beneventum and Ancona; and the great bridge of stone which Trajan ordered to be built over the Danube in the year 104, which was esteemed the most magnificent of all the works of that emperor. One day as Trajan was discoursing with this architect upon the buildings he had raised at Rome, Hadrian ventured to give his judgment, and showed he understood nothing of the matter. Apollodorus turned upon him bluntly, and said to him, "Go, paint gourds, for you are very ignorant of the subject we are talking upon." Hadrian at this time boasted of his painting gourds well. On Hadrian's elevation to the throne, Apollodorus was banished. He composed in his exile a treatise on Warlike Engines (πολιορκητικά), in a preface to which he supplicated the indulgence of the emperor. Hadrian sent him soon after the plan of a temple of Venus, which he had himself designed. Apollodorus criticized its dimensions, and remarked, "that if the goddess wished to rise and go out of the temple, she could not find room." This, with the former freedom of Apollodorus, so offended Hadrian, that he put the artist to death, on the pretext of imaginary crimes.—(Dion Cassius, lxix.)

APOLLONIA, an ancient city of Illyricum, near the mouth of the Avus, distinguished as a seat of learning towards the end of the Roman republic. This name was also borne by many other places.

Apollonia, a propitiatory festival solemnized at Sicyon in honour of Apollo and Artemis (Diana), to avert a pestilence. *Paus.* ii. 7. § 7.

APOLLONICON. See Organ.

APOLLONIUS *of Alabanda*, surnamed Molo, a distinguished Greek rhetorician, the instructor of Cæsar and of Cicero. He settled at Rhodes, and in the dictatorship of Sulla, was sent as ambassador from the Rhodians to Rome. He was the first Greek who addressed the senate without the aid of an interpreter. Cicero renewed his studies under him when he afterwards visited Rhodes on his return from Asia. The works of Apollonius have perished.

Another rhetorician of the same name, likewise a native of Alabanda, and an inhabitant of Rhodes, was surnamed the *Effeminate* (ὁ Μαλακὸς). Both are mentioned by Cicero with high respect.—Cicero, *Brutus*, 89, 90, 91; *De Inv.* i. 56; *De Orat.* i. 17, 28; Quintil. iii. 1. § 16; xii. 6, § 7, &c.

Apollonius, surnamed *Dyscolus* (Δύσκολος), or the *Crabbed*, was a native of Alexandria, and lived in the reigns of Hadrian and Antoninus Pius. Priscian calls him "*grammaticorum princeps*." He was the first systematic writer on grammar, and his extant treatises on various branches of the science, display great ingenuity and vigour of thought. These are, 1. On Syntax; 2. On the Pronoun; 3. On Conjunctions; 4. On Adverbs. The best edition of the Syntax is that of Bekker, Berlin, 1817.

Apollonius *of Perga*, in Pamphylia, is one of the most illustrious of the ancient Greek geometricians. The date of his birth has not been precisely ascertained; but as he flourished under Ptolemy Philopater, who died in the year 205 B.C., after a reign of 16 years, it is conjectured that he was born about the middle of the third century before our era, and that he was about 40 years posterior to Archimedes. He studied at Alexandria under the successors of Euclid, and is pre-eminently distinguished among the disciples of that illustrious school, in which the mathematical sciences were at all times held in the highest estimation.

Few of the numerous compositions of Apollonius have escaped the ravages of time; but the description which has been given of them by Pappus, in the preface to the seventh book of the *Mathematical Collections*, explains their nature and value, and gives the admirers of the ancient analysis great reason to regret the loss of those which have perished. The most celebrated of his productions was the treatise on the *Conic Sections;* a work which, according to the testimony of Geminius Rhodius, was regarded with so much admiration by the contemporaries of

its author, that they bestowed on him the title of the *Great Geometrician*. This title is justified by the excellence of the work, which is unquestionably far superior to any treatise on the subject which we know to have existed among the ancients, and which has not indeed, in some respects, been surpassed in modern times. But while we bestow this praise on the treatise of Apollonius, we are not to suppose that he was the inventor of all, or even the greater part, of the properties which are demonstrated in it. Several treatises on the conic sections are known to have existed previously, in which the theory of these curves seems to have been prosecuted to a very considerable length. Pappus mentions, in particular, in terms of the highest eulogy, the five books on Solid Loci, or the conic sections, which were composed by Aristæus *the ancient*, who lived about 350 years B. C.; and the construction given by Menechmus, of the problem to find two mean proportionals between two given straight lines, which leads to the duplication of the cube, shows that the disciples of Plato had advanced far in the same department of geometry. In fact, as it was the object of Apollonius to give a complete treatise of the conic sections, he did not scruple to avail himself of the discoveries of his predecessors, and, accordingly, embodied in his own work what had previously been done by Aristæus, Eudoxus of Cnidus, Menechmus, Euclid, Conon, Thrasidæus, Nicoteles, and others. It is now impossible to distinguish the propositions which were borrowed from his predecessors from those which were invented by himself; but it is certain that he both made great additions to the theory of the conic sections, and improvements in the manner of treating it. Eutocius informs us that Apollonius was the first who showed that all the three sections may be cut from the same cone, by varying the position of the intersecting plane; for previous authors had always supposed the plane of the section perpendicular to the side of the cone,—an hypothesis which requires that the three sections be cut from three cones of different species, namely, the parabola from a right-angled cone, the ellipse from an obtuse, and the hyperbola from an acute. It has, however, been established by Guido Ubaldus, in his commentary on the second book of the *Æquiponderantes* of Archimedes, that the Syracusan geometer was acquainted with the fact, that the three sections may be derived from the same cone. The generalization is indeed so very obvious, that we can scarcely persuade ourselves that it was not previously made by the more ancient writers; and it is probable, that if they usually assumed the cutting plane to have a particular position with reference to the cone, it was only on account of some facilities which that hypothesis afforded them in establishing the fundamental properties of the sections. Pappus ascribes to Apollonius the names by which the three sections are now distinguished and characterized: the term *Parabola*, however, occurs in the writings of Archimedes.

Of the eight books which Apollonius composed on the conic sections, the first four only have reached us in the original Greek. Three more have been preserved through the medium of an Arabic version; the last is unfortunately lost. A Latin translation of the first four was published by Memmius, at Venice, in 1537; and another, much more accurate, by Commandine, in 1568, with the addition of the commentary of Eutocius, and the lemmas of Pappus to all the eight books. Hitherto the last four books had not been discovered; but as the nature of their contents was sufficiently known from the indications of Pappus, several attempts were made to supply their loss by a restoration. Maurolycus, a Sicilian geometer of the 16th century, successfully commenced the theory of the fifth and sixth books; and Viviani, the last and favourite disciple of the illustrious Galileo, was employed on the same subject, when two different manuscript versions of the work of Apollonius were accidentally brought to light. Among a number of Arabic manuscripts brought from the East by Golius, one was found which contained seven books of the conics. Golius was sufficiently instructed in geometry to be aware of the value of his discovery; he hastened to communicate it to the mathematicians of that time, and proposed to publish a translation of the work. This project, however, failed from some cause which has not been explained; and, notwithstanding the intimation which had been given, the last four books still continued to be regarded as lost, till the year 1658, when Alphonso Borelli, the celebrated author of the treatise *De Motu Animalium*, happened to discover, in the library of the Medici at Florence, an Arabic manuscript with the following inscription: *Apollonii Pergæi Conicorum Libri Octo*. Borelli obtained permission to carry this manuscript to Rome, where, with the assistance of Abraham Ecchellensis, he translated the fifth, sixth, and seventh books. Notwithstanding the inscription, the eighth book was wanting; and as this was also the case with regard to the manuscript of Golius, it seems probable that it had not been translated into Arabic.

The last four books of the conics of Apollonius formed a considerable part of what may be termed the transcendental geometry of the ancients; and they exhibit some of the most elegant and successful applications of the geometrical analysis. The fifth book, for example, which treats of the greatest and least lines that can be drawn from given points to the peripheries of the curves, contains nearly all the properties of normals and radii of curvature which are now generally investigated by the aid of the differential calculus, and almost anticipates the admirable theory of involutes and evolutes which confers so brilliant a lustre on the name of Huygens. The seventh book also contains some theorems which, although they have now passed into the elements, are sufficiently difficult and remote to afford scope for the exercise of address and ingenuity, even when their investigation is attempted by the modern analysis. Dr Halley, guided by the description of Pappus, divined the contents of the eighth book, and published a magnificent edition of the whole at Oxford in 1710.

The other treatises of Apollonius which are mentioned by Pappus are the following:—1*st*, The Section of Ratio, or Proportional Sections; 2*d*, the Section of Space; 3*d*, the Determinate Sections; 4*th*, the Tangencies; 5*th*, the Inclinations; 6*th*, the Plane Loci. Each of these was divided into two books, and, with the *data* of Euclid and the *porisms*, they formed the eight treatises which, according to Pappus, constituted the body of the ancient analysis. Of the above treatises of Apollonius, the first only has reached us through an Arabic translation. It was discovered in Arabic among the Selden manuscripts in the Bodleian Library at Oxford, by Dr Edward Bernard, who commenced a translation of it, from which, however, he was deterred by the difficulties occasioned by the extreme inaccuracy of the manuscript before he had finished a tenth part. This small portion of the translation was revised by Dr David Gregory; the rest was translated, or more properly speaking, divined, by Dr Halley, who published it in 1706, together with the analogous treatise on the *Section of Space*, which he had restored after the indication of its contents given by Pappus. The general problem resolved in the first treatise, although it is branched out into a great variety of cases, may be comprehended in the following enunciation: "Two straight lines being given by position, together with a point in each, it is required to draw through a third given point a straight

 line intersecting the two former straight lines, so that the segments intercepted between the given points and the points of intersection with the third line may be to each other in a given ratio." The problem which forms the subject of the second treatise differs from the above only in requiring that the intercepted segments on the two straight lines given by position shall contain a given rectangle.

The object of the treatise on the *Determinate Sections* was "to find a point in a straight line given by position, the rectangles or squares of whose distances from given points in the given straight line shall have a given ratio." A restoration of this and the two preceding treatises was attempted by Snellius; but although he certainly resolved the problems which had been proposed by Apollonius, his solutions were far inferior in point of elegance to those of the Greek geometer. The discovery of the treatise on the Section of Ratio enabled a comparison to be made of the restored with the original work. Some cases of the *Determinate Section* were also resolved by Alexander Anderson of Aberdeen, in his supplement to the *Apollonius Redivivus*, published at Paris in 1612. But by far the most complete and elegant restoration of the problem was given by Dr Simson of Glasgow, with two additional books on the same subject. It has been published among his posthumous works.

The treatise on *Inclinations*,—the object of which was to insert a straight line of a given length, and tending to a given point, between two lines (straight lines or circles) given by position,—was first investigated by Marinus Ghetaldus, a patrician of Ragusa, afterwards by Hugo de Omerique in his ingenious treatise on the *Geometrical Analysis*, published at Cadiz in 1698. The different cases of the problem have been resolved in a very elegant manner by Dr Horsley, who published his restoration in 1770.

The treatise *de Tactionibus*, which relates to the contact of circles and straight lines, has afforded exercise for the ingenuity of many modern mathematicians. The general problem which it embraces may be enunciated as follows: Three things (points, straight lines, or circles) being given by position, it is required to describe a circle which may pass through the given points and touch the given straight lines and circles. The most difficult case of the problem is that in which the three things given are circles; the question being then to determine the centre and radius of a circle, which shall touch these circles given in magnitude and position. This problem, which is now considered as quite elementary, possesses an historical interest on account of the great names connected with its solution. It was proposed by Vieta, the most skilful geometrician of the 16th century, to Adrianus Romanus, who, in constructing it, employed the very obvious consideration of the intersection of two hyperbolas. Such a solution of a plane problem, which ought to be constructed by means of straight lines and circles only, was very far from being satisfactory to Vieta: he therefore himself proposed a more geometrical construction, and restored the whole treatise of Apollonius, in a small work which he published at Paris in 1660 under the title of *Apollonius Gallus*. The treatise of Vieta is entitled to the praise of great ingenuity, but it falls far short of the geometrical elegance of the known productions of Apollonius; and simpler solutions have since been found of the more difficult cases of the general problem. An algebraic solution of the same question was attempted by Descartes; but the equations at which he arrived were so exceedingly complicated, that he himself ingenuously confessed that he should not be able to construct one of them in a shorter time than three months. The Princess Elizabeth of Bohemia, who carried on an epistolary correspondence with Descartes, gave a solution of the same kind. Newton himself, in his *Universal Arithmetic*, condescended to consider this problem; but he succeeded little better than Vieta, whose method he followed. In the 16th lemma of the first book of the *Principia*, he has, however, given a different and simpler investigation, and reduced with great skill the two hyperbolic loci of Adrianus Romanus to the intersection of two straight lines. Simple geometrical solutions, since that of Dr Simson was published, are to be found in every elementary work. In speaking of this problem, Montucla observes, that it is one of those to which the algebraic analysis applies with difficulty. His opinion, however, would have been different had he lived to see the extremely simple and elegant algebraic investigation given by Gergonne in the *Annales des Mathématiques*, not only of this, but of the analogous problem in space which was proposed by Descartes to Fermat, viz. to describe a sphere touching four spheres given by position. In fact, it would be difficult to select a problem in elementary geometry better calculated to display the resources and pliability of the algebraic calculus, than this very one which had been considered as belonging so exclusively to the analysis of the ancients. A very full and interesting historical account of this problem is given in the preface to a little work of Camerer, entitled *Apollonii Pergæi quæ supersunt, ac maxime Lemmata Pappi in hos libros, cum Observationibus*, &c. Gothæ, 1795, 8vo.

The last of the treatises mentioned by Pappus,—*de Locis Planis*,—is only a collection of properties of the straight line and circle, and corresponds to the construction of equations of the first and second degree. It has been restored in the true spirit of the ancient geometry by Dr Simson, whose treatise well deserves the attention of the student.

Besides the works which we have now enumerated, we are informed, by the fragment of the second book of Pappus, published among the works of Dr Wallis, that Apollonius occupied himself with arithmetical researches, and composed a treatise on the multiplication of large numbers. Astronomy is also indebted to him for the discovery, or at least for the demonstration, of the method of representing, by means of epicycles and deferents, the phenomena of the stations and retrogradations of the planets. He appears also to have been the inventor of the method of projections, and has the distinguished merit of having been the first who attempted to found astronomy on the principles of geometry, and establish an alliance between these two sciences which has been productive of the greatest benefit to both.

Of the personal character of this most assiduous and inventive geometrician, nothing is known excepting what may be gathered from a few unfavourable hints thrown out by Pappus. Pappus describes him as vain, arrogant, envious of the reputation of others, and inclined to depreciate their merit; and contrasts him with the amiable and disinterested Euclid, who was always ready to allow to every one his just share of praise, and who manifested on every occasion the most benevolent feelings towards all men, especially towards those who laboured to improve or extend the science of geometry. The charge of appropriating to himself the discoveries of Archimedes, which was brought against Apollonius by Heraclius, had probably no other foundation than the boastful manner in which he spoke of his own discoveries, and affected to despise those of other mathematicians; for, as has been well remarked, pretensions pushed too far excite in the rest of mankind a sort of re-action of self-love, which leads them to contest the most legitimate titles. But whatever may have been the case with regard to the per-

sonal qualities of Apollonius, the powers of his mind and his unwearied industry command universal admiration. The great value attached to his productions by the ancients is manifest from the number and celebrity of the commentators who undertook to explain them. Among these we find the names of Pappus, the learned and unfortunate Hypatia, Serenus, Eutocius, &c.

The remarkable editions of the works of Apollonius are the following:—1. *Apollonii Pergæi Conicorum libri quatuor, ex versione Frederici Commandini.* Bononiæ, 1566, fol. 2. *Apollonii Pergæi Conicorum libri* v. vi. vii. *Paraphraste Abalphato Asphanensi nunc primum editi: Additus in calce Archimedis Assumtorum liber, ex Codicibus Arabicis Manuscr.: Abrahamus Ecchellensis Latinos reddidit: J. Alfonsus Borellus curam in Geometricis Versioni contulit, et Notas uberiores in universum opus adjecit.* Florentiæ, 1661, fol. 3. *Apollonii Pergæi Conicorum libri octo, et Sereni Antissensis de Sectione Cylindri et Coni libri duo.* Oxoniæ, 1710, fol. (This is the splendid edition of Dr Halley.) 4. The edition of the first four books of the Conics given in 1675 by Barrow. 5. *Apollonii Pergæi de Sectione Rationis libri duo: Accedunt ejusdem de Sectione Spatii libri duo Restituti: Præmittitur,* &c. *Opera et Studio Edmundi Halley.* Oxoniæ, 1706, 4to.

See Bayle's *Dictionary;* Bossut, *Essai sur l'Hist. Gén. des Math.*, tome i.; Montucla, *Hist. des Math.*, tome i. Vossius *de Scient. Math.;* Simson's *Sectiones Conicæ*, preface; and Hutton's *Mathematical Dictionary.* (T. G.)

Apollonius, the author of the *Argonautics*, and surnamed the Rhodian, from the place of his residence, is supposed to have been a native of Alexandria, where he is said to have recited some portion of his poem while he was yet a youth. Finding it ill received by his countrymen, he retired to Rhodes, where he is conjectured to have polished and completed his work, supporting himself by the profession of rhetoric, and receiving from the Rhodians the freedom of their city. He at length returned with considerable honour to the place of his birth, succeeding Eratosthenes in the care of the Alexandrian library in the reign of Ptolemy Euergetes, who ascended the throne of Egypt in the year before Christ 246. That prince had been educated by the famous Aristarchus, and rivalled the preceding sovereigns of his liberal family in the munificent encouragement of learning. Apollonius was a disciple of the poet Callimachus; but their connection ended in the most violent enmity, which was probably owing to some degree of contempt expressed by Apollonius for the light compositions of his master. The learned have vainly endeavoured to discover the particulars of their quarrel. The only work of Apollonius which has descended to modern times is his poem above mentioned, in four books, on the Argonautic expedition. Both Longinus and Quintilian have assigned to this work the mortifying character of mediocrity. It was published for the first time at Florence in 1496, with the ancient Greek Scholia, in a 4to volume, now exceedingly rare. There is an excellent edition by Brunck, published in 1780, and another by Beck, published in 1797; but the best is that of Professor Schäfer, printed at Leipsic in 2 vols. 8vo, in 1810–13.

The *Argonautics* have been well translated into English verse by Fawkes and Green in 1780; another translation in English verse, with critical notes, was published by W. Preston in 1803.

Apollonius and Tauriscus of *Tralles*, the sculptors of the famous *Farnese Bull*, a group representing Zethus and Amphion tying the revengeful Dirce to the tail of a wild bull. This work is now at Naples. There were several other sculptors named Apollonius.

Another Apollonius, a sophist, wrote a Homeric Lexicon, which was first published by Villoison. His Λέξεις Ὁμηρικαί appeared in two vols. 4to, at Paris, in 1773.

Apollonius *of Tyana*, a celebrated Pythagorean philosopher, was born at Tyana, the capital of Cappadocia, a few years before the Christian era. At the age of 14 he was sent by his father to Tarsus, to study grammar and rhetoric under the Phœnician Euthydemus; but finding the vain and luxurious manners of that city unfavourable to serious study, he retired, with his father's permission, to the neighbouring town of Ægæ, where he spent most of his time in the temple of Æsculapius, in the company of priests and philosophers. Here he fell in with Euxenus, a philosopher who professed the principles of Pythagoras, but followed in his practice the less rigid maxims of Epicurus. Apollonius received with enthusiasm the Pythagorean instructions of Euxenus, and with more consistency than his master, determined at the age of 16 to mould his future life by the precepts of the Samian sage. Thenceforth renouncing the pleasures and luxuries of life, he devoted himself to the cultivation of his soul, and the improvement of his fellow-men. Abjuring the use of animal flesh and of wine, he fed on the simple fruits of the earth, wore no clothing but linen, and no sandals on his feet, suffered his hair to grow, and slept on the hard ground. The still more difficult penance of a five years' silence, prescribed by Pythagoras to his disciples, was a few years after strictly observed by Apollonius. This period he passed chiefly in Pamphylia and Cilicia, enduring the painful trial of passing through scenes of violence and disorder without suffering even a murmur to pass his lips; successful, however, if his admiring biographer may be credited, in restraining tumult and excess by the look of his countenance, or the silent eloquence of his hand. At the city of Aspendus, he found the inhabitants rising in mutiny against the governor, whom they unjustly blamed for the general scarcity of corn. The presence of Apollonius awed them into silence, and the governor urged in his own defence that the wealthy citizens who hoarded their corn were the authors of the famine. The excited populace were hurrying to take vengeance on the monopolizers, and plunder their stores, when Apollonius, by silent signs, hushed their fury, and the hoarders of the corn were brought into his presence. With difficulty restraining his voice, amid the tears of perishing women and children and old men, he wrote on a tablet the following words:—"Apollonius to the monopolizers of corn in Aspendus, greeting! The earth is the common mother of all, for she is just. You are unjust, for you have made her only the mother of yourselves: and if you will not cease from thus doing, I will not suffer you to remain upon her." This just rebuke, says Philostratus, had the desired effect: the market was filled with grain, and the city recovered from its distress. This story, whether true or not, may be taken as a fair indication of the real character of Apollonius, both as to the general tenor of his moral teaching, and his high and mysterious pretensions.

After spending some time at Antioch, Apollonius extended his travels into the East, and wandered over Assyria, Persia, and India, conversing with Magi, Brahmins, Gymnosophists, and priests, visiting the temples, preaching a purer morality and religion than he found, and attracting wherever he went admiration and reverence. At Nineveh he met with Damis, who became his disciple and the companion of his journeyings, and left those doubtful records of his life which Philostratus made use of, and probably improved upon. He afterwards visited Egypt, Greece, and Italy, and died, as is supposed, at Ephesus, at a very advanced age. His biographer has represented his death as involved in doubt and mystery, with the view of heightening the reverence due to his hero.

After his death Apollonius was worshipped with divine

honours for a period of four centuries. A temple was raised to him at Tyana, which obtained from the Romans the immunities of a sacred city. His statue was placed among those of the gods, and his name was invoked as a being possessed of superhuman powers. The defenders of Paganism, at the period of its decline, placed the life and miracles of Apollonius in rivalry to those of Christ; and some modern Deists have not disdained to make the same unworthy comparison.

The life of Apollonius by Philostratus, composed about 120 years after the philosopher's death, by order of Julia, wife of the Emperor Severus, is the only source of our information regarding him. Founded, as it is, on the insufficient testimony of Damis, combined with vague and exaggerated traditions, we are left to draw our estimate of Apollonius from mere probability. See Philostratus. It would seem, then, that though he may very possibly have been led, in his desire to strengthen his influence over men's minds, to use artifices and pretensions unworthy of a true sage, he was far from having been a vulgar or shallow impostor. With some of the spirit of a moral and religious reformer, he appears to have attempted, though vainly, to animate with a new and purer life the expiring breath of Paganism. His journey to the East was probably directed by the wish to trace the original traditions of the human race to their native source, believing, as he seems to have done, that these had been corrupted by the impure mythology of an artful priesthood. The story already quoted illustrates his doctrine that the earth was the common home of the human family, and that its inhabitants could attain true happiness only in the recognition of their mutual brotherhood. He inculcated the uselessness of supplication and of sacrifice, as unworthy of the Divine majesty, proclaiming the only acceptable offering to be a pure and devout heart.

In a philosophical relation, Apollonius may be regarded as the precursor of the Alexandrian philosophy, by bringing philosophy and religion into union, and attempting to combine the philosophical spirit of Greece with the mystical religion of the East. Of the authentic works of Apollonius none are extant but his *Apology*, preserved along with the life by Philostratus.

APOLLOS, in *Scripture History*, a Jew of Alexandria, who came to Ephesus during the absence of St Paul at Jerusalem (Acts xviii. 24). Apollos was an eloquent man, and well versed in the Scriptures, and preached in the synagogue, with zeal and fervour the doctrine of a Messiah, knowing as yet "only the baptism of John." Aquila and Priscilla having heard him, took him home with them, instructed him more fully in the doctrines of the Gospel, and baptized him.

Some time after this he travelled into Achaia; and, having come to Corinth, was there very useful in convincing the Jews out of the Scriptures, and demonstrating to them that Jesus was the Christ. Thus he watered what St Paul had planted in this city. (1 Cor. iii. 6.) But the great affection which his disciples entertained for him threatened to produced a schism, some saying, I am of Paul, others, I am of Apollos, I am of Cephas. This division, however, which St Paul speaks of in the chapter last quoted, did not prevent that apostle and Apollos from being closely united by the bonds of charity. Apollos hearing that the apostle was at Ephesus, went to meet him, and was there when St Paul wrote the first epistle to the Corinthians; wherein he testifies that he had earnestly entreated Apollos to return to Corinth, but hitherto had not been able to prevail with him; that nevertheless he gave him room to hope that he would go when he had an opportunity. St Jerome says that Apollos was so dissatisfied with these divisions at Corinth, that he retired into Crete with Zenas, a doctor of the law; and that this disturbance having been appeased by St Paul's letter to the Corinthians, Apollos returned to this city, and became its bishop. The Greeks made him bishop of Duras, others say he was bishop of Iconium in Phrygia, and others that he was bishop of Cæsarea.

APOLLYON, a Greek word that signifies *the destroyer*, and answers to the Hebrew *Abaddon*. See Abaddon.

APOLOGUE, in *Literature*, an ingenious method of conveying instruction by means of a feigned relation called a *moral fable*. The only difference between a parable and an apologue is, that the former, being drawn from what passes among mankind, requires probability in the narration; whereas the apologue, being taken from the supposed actions of brutes, or even of things inanimate, is not tied down to the strict rules of probability. The Æsopic fables are a model of this kind of writing.

APOMYOS (ἀπό, and μυῖα, *a fly*), in the *Heathen Mythology*, a name under which Zeus was worshipped at Elis, and Hercules as well as Zeus at the Olympic games. These deities were supplicated under this name to destroy or drive away the vast number of flies which always attended at the great sacrifices; and in those which accompanied the Olympic games, the first was always to the *Apomyos*, or *Myiagrus Theos*, that he might drive away the flies from the rest. The usual sacrifice was a bull.

APONO, Peter d', one of the most famous philosophers and physicians of his age, born in the year 1250, in a village about four miles from Padua. He was suspected of magic, and prosecuted by the Inquisition. "The common opinion of almost all authors," says Naudé, "is, that he was the greatest magician of his age; that he had acquired the knowledge of the seven liberal arts by means of the seven familiar spirits, which he kept inclosed in a crystal; and that he had the dexterity to make the money he had spent come back into his purse." The same author adds, that he died before the process against him was finished, being then in the 66th year of his age; and that, after his death, they ordered him to be burnt in effigy, in the public place of the city of Padua. He was the author of various works, the most remarkable of which are the following: *Conciliator Differentiarum Philosophorum*, first published in 1471; *De Venenis eorumque Remediis*, which was translated into French by Boet in 1593; *Expositio Problematum Aristotelis*, 1475; *Geomantia*, 1549; *Dionocides digestus Alphabet. Ord.* 1521.

APOPEMPTIC (ἀποπεμπτικά), in *Ancient Poetry*, a hymn addressed to a stranger on his departure from a place to his own country. The ancients had certain holydays wherein they took leave of the gods with *apopemptic* songs, as supposing them returning each to his own country. The deities having the patronage of divers places, it was but just to divide their presence, and allow some time to each. Hence it was that among the Delians and Milesians we find feasts of Apollo, and among the Argives feasts of Diana, called *Epidemiæ*, as supposing these deities then more peculiarly resident among them. On the last day of the feast they dismissed them, following them to the altars with *apopemptic* hymns.

APOPHORETA (ἀποφόρητα), in *Antiquity*, presents which the guests at an entertainment carried home with them. This was a common practice at all times, but especially at festivals, such as the Saturnalia.—See Martial. l. 14. Suet. *Vesp.* 19. *Cal.* 55. *Aug.* 75.

APOPHTHEGM (ἀπόφθεγμα), a short, sententious, and instructive remark.

APOPHYLLITE, a mineral belonging to the zeolite family. See Mineralogy.

APOPLEXY (ἀπόπληξις), a distemper in which the patient is suddenly deprived of all his senses, and of voluntary motion.

APORIA (ἀπόρια), a figure in *Rhetoric*, by which the speaker shows that he doubts where to begin for the multi-

tude of matter, or what to say in some strange and ambiguous thing, and, as it were, argues the case with himself.

APOSIOPESIS, in *Rhetoric*, afterwards called *reticency* and *suppression*, a figure by which a person really speaks of a thing, at the same time that he makes a show as if he would say nothing of it. The word comes from ἀποσιωπάω, *I am silent*. Example: "*I declare to you that his conduct —but we must not now lose time in words.*"

APOSPHRAGISMA (from ἀπό, and σφραγίζω, *I seal*), in *Antiquity*, the figure or impression of a seal.

APOSTASY (ἀπόστασις), a going away, or defection from one's original profession or party.

A POSTERIORI. See A PRIORI.

APOSTLE (ἀπόστολος), properly signifies a messenger or person sent by another upon some business; and hence, by way of eminence, denotes one of the disciples commissioned by Jesus Christ to preach the gospel.

Christ selected twelve out of the number of his disciples to be invested with the apostleship. Their names were Simon Peter, Andrew, James the Greater, John, Philip, Bartholomew, Thomas, Matthew, James the Less, Jude, surnamed Lebbeus or Thaddeus, Simon the Canaanite, and Judas Iscariot. Of these, Simon, Andrew, James the Greater, and John, were fishermen, and Matthew a publican, or receiver of the public revenue; of what profession the rest were we are not told in Scripture, though it is probable they were fishermen.

Our Lord's first commission to his apostles was in the third year of his public ministry, about eight months after their solemn election; at which time he sent them out by two and two. They were to make no provision of money for their subsistence in their journey, but to expect it from those to whom they preached They were to declare that the kingdom of heaven, or the Messiah, was at hand; and to confirm their doctrine by miracles. They were to avoid going either to the Gentiles or to the Samaritans, and to confine their preaching to the people of Israel. In obedience to their Master, the apostles went into all the parts of Palestine inhabited by the Jews, preaching the gospel and working miracles. The evangelical history is silent as to the particular circumstances attending this first preaching of the apostles, and only informs us that they returned and told their Master of all that they had done.

Their second commission, just before our Lord's ascension, was of a more extensive and particular nature. They were now not to confine their preaching to the Jews, but to "go and teach ALL nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost." Accordingly, they began publicly, after our Lord's ascension, to exercise the office of their ministry, working miracles daily in proof of their mission, and making great numbers of converts to the Christian faith. This alarmed the Jewish Sanhedrim; whereupon the apostles were apprehended, and being examined before the high priest and elders, were commanded not to preach any more in the name of Christ. But this injunction did not terrify them from persisting in the duty of their calling; for they continued daily, in the temple, and in private houses, teaching, and preaching the gospel.

After the apostles had exercised their ministry for twelve years in Palestine, they resolved to disperse themselves in different parts of the world, and agreed to determine by lot what parts each should take. According to this division, St Peter went into Pontus, Galatia, and other provinces of the Lesser Asia; St Andrew had the vast northern countries of Scythia and Sogdiana allotted to his portion; St John's was partly the same with Peter's, namely, the Lesser Asia; St Philip had the Upper Asia assigned to him, with some parts of Scythia and Colchis; Arabia Felix fell to St Bartholomew's share; St Matthew preached in Chaldea, Persia, and Parthia; St Thomas preached likewise in Parthia, as also to the Hyrcanians, Bactrians, and Indians; St James the Less continued in Jerusalem, of which church he was bishop; St Simon had for his portion Egypt, Cyrene, Libya, and Mauritania; St Jude, Syria and Mesopotamia; and St Matthias, who was chosen in the room of the traitor Judas, Cappadocia and Colchis. Thus, by the dispersion of the apostles, Christianity was very early planted in a great many parts of the world. We have but very short and imperfect accounts of their travels and actions.

In order to qualify the apostles for the arduous task of converting the world to the Christian religion, they were, in the first place, miraculously enabled to speak the languages of the several nations to whom they were to preach; and, in the second place, were endowed with the power of working miracles, in confirmation of the doctrines they taught; gifts which were unnecessary, and therefore ceased, in the after ages of the church, when Christianity came to be established by the civil power.

St Paul is frequently called the *apostle* by way of eminence; and the *apostle of the Gentiles*, because his ministry was chiefly made use of for the conversion of the Gentile world, as that of St Peter was for the Jews, who is therefore styled the *apostle of the circumcision*. The several apostles are usually represented with their respective badges or attributes: Peter with the keys; St Paul with a sword; St Andrew with a cross or saltier; St James minor with a fuller's pole; St John with a cup, and a winged serpent flying from it; St Bartholomew with a knife; St Philip with a long staff, whose upper end is formed into a cross; St Thomas with a lance; St Matthew with a hatchet; St Matthias with a battle-axe; St James major with a pilgrim's staff and a gourd bottle; St Simon with a saw; and St Jude with a club.

APOSTLE was also used among the Jews for a kind of officer anciently sent into the several parts and provinces in their jurisdiction, by way of visitor or commissary, to see that the laws were duly observed, and to receive the monies collected for the reparation of the temple, and the tribute payable to the Romans.

APOSTLE, in the *Greek Liturgy*, is particularly used for a book containing the Epistles of St Paul, printed in the order in which they are to be read in churches through the course of the year. Another book of the like kind, containing the Gospels, is called Εὐαγγέλιον, *Gospel*. The Apostle, of late days, has also contained the other canonical epistles, the Acts of the Apostles, and the Revelation. Hence it is also called *Acts of the Apostles*, Πραξαπόστολος; that being the first book in it.

APOSTLE is also thought by many to have been the original name for bishops, before the denomination *bishop* was appropriated to their order. Thus Theodoret says expressly, the same persons were anciently called promiscuously both bishops and presbyters, while those who are now called bishops were called *apostles*.

APOSTLES' CREED, a formula or summary of the Christian faith, drawn up, according to Rufinus, by the apostles themselves, as a rule of faith, and as a *word of distinction*, by which they were to know friends from foes. Baronius and some other authors conjecture that they did not compose it till the second year of the reign of Claudius, a little before their dispersion. As to their manner of composing it, some fancy that each apostle pronounced his article, which is the reason of its being called *symbolum apostolicum;* it being made up of sentences jointly contributed, after the manner of persons paying each their club (*symbolum*) or share of a reckoning.

But there are reasons which may induce us to question whether the apostles composed any such creed as this. For, first, neither St Luke in the Acts, nor any other ecclesias-

tical writer before the fifth century makes any mention of an assembly of the apostles in order to the composing of a creed. Secondly, The fathers of the first three centuries, in disputing against the heretics, endeavoured to prove that the doctrine contained in this creed was the same which the apostles taught; but they never pretend that the apostles composed it. Thirdly, If the apostles had made this creed, it would have been the same in all churches and in all ages; and all authors would have cited it after the same manner. But the case is quite otherwise. In the second and third ages of the church there were as many creeds as authors, and one and the same author sets down the creed after a different manner in several places of his works, which is an evidence that there was not at that time any creed which was reputed the production of the apostles. In the fourth century Rufinus compares together the three ancient creeds of the churches of Aquileia, Rome, and the East, which differ very considerably in the terms. Besides, these creeds differed not only in the terms and expressions, but even in the articles, some of which were omitted in one or other of them, such as those of the *descent into hell*, the *communion of the saints*, and the *life everlasting*. From these reasons it may be gathered, that though this creed may be said to be that of the apostles in regard to the doctrines contained therein, yet it is not to be referred to them as the authors and first composers of it. Who was the true author of it, it is not easy to determine, though its great antiquity may be inferred from this, that the whole form, as it now stands in the English liturgy, is to be found in the works of St Ambrose and Rufinus, both of whom flourished in the fourth century.

APOSTOLEIS (ἀποστολεῖς), ten public officers at Athens who superintended the equipment and provisioning of the fleet by the trierarchs.

APOSTOLIANS, a sect of the Mennonites, which first sprung up in the year 1663, and derived its name from Apostool, one of the Mennonite ministers at Amsterdam. They concurred with them in doctrine, and admitted to their communion those only who professed to believe all the sentiments which are contained in their public confession of faith. See MENNONITES.

APOSTOLIC, in the *Primitive Church*, was an appellation given to all such churches as were founded by the apostles; and even to the bishops of those churches, as being the reputed successors of the apostles. These were confined to four, viz., Rome, Alexandria, Antioch, and Jerusalem. In after times other churches assumed the same quality, on account, principally, of the conformity of their doctrine with that of the churches which were apostolical by foundation, and because all bishops held themselves successors of the apostles, or acted in their dioceses with the authority of apostles.

APOSTOLICAL FATHERS is an appellation usually given to the writers of the first century who employed their pens in the cause of Christianity. Of these writers, Cotelerius, and after him Leclerc, have published a collection in two volumes, accompanied with their own annotations and the remarks of other learned men.

APOSTOLICI, or APOSTOLICS, was a name assumed by three different sects, on account of their pretending to imitate the manner and practice of the apostles. The first apostolici, otherwise called *Apotactitæ* and *Apotactici*, rose out of the Encratitæ and Cathari in the third century. They made profession of abstaining from marriage, and the use of wine, flesh, money, &c. Gerhard Sagarelli was the founder of the second sect; he obliged his followers to go from place to place as the apostles did, to wander about clothed in white, with long beards, dishevelled hair, and bare heads, accompanied by women, whom they called their spiritual sisters. They likewise renounced all kinds of property and possessions, inveighed against the growing corruption of the church of Rome, and predicted its overthrow, and the establishment of a purer church on its ruins. Sagarelli was burnt alive at Parma in the year 1300, and was afterwards succeeded by Dulcinus, who added to the character of an apostle that of a prophet and of a general, and carried on a bloody and dreadful war for the space of more than two years against Reynerius, bishop of Vercelli: he was at length defeated, and put to death in a barbarous manner, in the year 1307. Nevertheless, the sect subsisted in France, Germany, and other countries, till the beginning of the fifteenth century, when it was totally extirpated under the pontificate of Boniface IX. The other branch of apostolici was of the twelfth century. These also condemned marriage, preferring celibacy, and calling themselves the chaste brethren and sisters; though each was allowed a spiritual sister, with whom he lived in a domestic relation: and on this account they have been charged with concubinage. They held it unlawful to take an oath, they set aside the use of baptism, and in many things imitated the Manichees. Bernard wrote against this sect of apostolici.

APOSTOLICUM is a peculiar name given to a kind of song or hymn, anciently used in churches. The apostolicum is mentioned by Greg. Thaumaturgus as used in his time. Vossius understands it as spoken of the apostles' creed: Suicer thinks this impossible, because the creed was then unknown in the churches of the East.

APOSTROPHE (ἀποστροφή), in *Rhetoric*, a figure by which a person who is either absent or dead is addressed as if he were present and attentive to us. It also signifies a diversion from the main subject of a discourse; as when an advocate, in an argument to the jury, turns and addresses some incidental remark to the court.

APOSTROPHE, in *Grammar*, the contraction of a word by the use of a comma; as *call'd* for *called*, *tho'* for *though*.

APOTACTITÆ, or APOTACTICI. See APOSTOLICI.

APOTEICHISMUS, in the *Ancient Military Art*, a kind of line of circumvallation drawn round a place in order to besiege it. This was also called *periteichismus*. The first thing the ancients went about when they designed to lay close siege to a place, was the apoteichismus, which sometimes consisted of a double wall or rampart, raised of earth; the innermost to prevent sudden sallies from the town, the outermost to keep off foreign enemies from coming to the relief of the besieged. This answered to what are called *lines of contravallation* and *circumvallation* among the moderns.

APOTHECARY. In Scotland this term is restricted to one who compounds and sells drugs, and is used synonymously with the term Druggist or Pharmaceutical Chemist. These have never in Scotland enjoyed any status higher than that of ordinary shopkeepers. In England, again, the term means a general practitioner in medicine who also dispenses and sells drugs to his patients or the public; and the Apothecaries' Company of London is not only one of the city corporations, but also by an act of parliament licenses the general practitioners over England and Wales to deal in or sell drugs.

From early records we learn that the different branches of the medical profession were not regularly distinguished till the reign of Henry VIII., when they had separate duties assigned them, and peculiar privileges. In 1518 the physicians of London were incorporated; and the barber-surgeons in 1540. These two bodies as soon as constituted overstepped their jurisdiction by prosecuting all those practitioners who did not belong to either body, and who constituted the great mass of the practitioners of the healing art. It was necessary, therefore, to pass an act in 1543 for the protection and toleration of these numerous irregular practitioners, to most of whom the term apothecary was applicable, as they usually had shops for the sale of medicines.

In April 1606 James I. incorporated the apothecaries as one of the city companies, uniting them with the grocers. On their charter being renewed in 1617 they were formed into a separate corporation, under the title of the "Apothecaries of the city of London." These apothecaries appear very soon to have begun to prescribe as well as to dispense medicines, which was resisted by the College of Physicians as an encroachment on their rights, but apparently unsuccessfully, as the apothecaries made good their claims. In 1722 an act was obtained empowering the Apothecaries' Company to visit the shops of all druggists who were not members of the company, and to destroy such drugs as they found unfit for use. They appear to have worked this act so rigorously, or rather oppressively, as to put down all druggists who were not members of their body. In 1748, great additional powers were given to the company by an act empowering them to appoint a board of ten examiners, without whose license none should be allowed to dispense medicines in London, or within a circuit of seven miles round it.

In 1815, however, an act was passed which gave the Apothecaries' Company an entirely new position, empowering a board of twelve of their number to have the sole right of examining and licensing apothecaries throughout England and Wales. It also enacted that from the 1st of August that year (excepting those already in practice), none but those licensed by them should have right to practise as an apothecary; and at the same time it was made imperative that candidates for examination should have served a five years' apprenticeship with a member of the company.

As in small provincial towns or villages, no one can practise without keeping a supply of drugs for his patients, this act has given the apothecaries the complete control of the medical profession in England. Every general practitioner must not only have their license, but must have served an apprenticeship with a member of their body. If a practitioner does not dispense drugs the Apothecaries' Company cannot interfere with him.

Before this act came into operation a large proportion of the medical practitioners of England were graduates of the universities of Edinburgh, Glasgow, and Dublin, or licentiates of the Royal Colleges of Physicians or Surgeons—none of whom could attain that status without a full and liberal course of medical education, and undergoing a rigorous examination. This act at once sunk the requirements of the medical practitioner to the lowest ebb; and we have the avowal of the company itself that the course of study required by the company for its license was of a very inferior description. Since 1832, chiefly in consequence of the outcry for medical reform, a much superior course of study has been demanded; but the practical working of the Apothecaries' Act of 1815 has been most hurtful to the medical profession in many respects, and justice demands that the attention of the legislature should be turned to this subject with the view of relieving the most pressing grievances. Though desirable that every medical practitioner should know the drugs he uses, and be able to dispense them, it does not follow that only those are capable of doing this who are licensed at Rhubarb Hall. All those who are recognized in any part of Her Majesty's dominions as regularly licensed practitioners, by possessing the diploma of a chartered licensing medical corporation, should most unquestionably be freed from the operation of this act. Till this be granted, the Apothecaries Act of 1815 must be considered as a foul blot on the Statute Book; and if the medical profession, instead of wasting, as they have done, time and money in the many late vain attempts at a chimerical uniformity of medical education and general union of the whole profession, were to have united for this point alone, it would never have been refused by government, and have relieved them from the only real grievance of which they have to complain. (J. S—K.)

APOTHECA (ἀποθήκη), a storeroom in the upper part of a house, where the Romans frequently kept their wine, in order that the smoke from below might mellow it. Hence the expression in Horace, *Descende, testa. Carm.* iii. 21. 7.

APOTHEOSIS, in *Antiquity*, a ceremony, whereby emperors and great men were enrolled among the gods. The word is derived from ἀπό, and Θεός, *God*. After the apotheosis, which they also called *deification* and *consecration*, temples, altars, and images were erected to the new deity; sacrifices, &c., were offered, and colleges of priests instituted. It was one of the doctrines of Pythagoras, which he had borrowed from the Chaldees, that virtuous persons after their death were raised into the order of the gods; and hence the ancients deified all the inventors of things useful to mankind, and those who had done any important services to the commonwealth.

APOTHESIS (from ἀπό and τίθημι), in the ancient churches, was a place with shelves for holding books, vestments, &c., on the south side of the chancel.

APOTOME, ἀποτομή, in *Geometry*, the difference between two incommensurable lines.

Apotome, a term used by the ancient Greek theoretical writers on musical sounds and intervals to signify that interval in the ratio of 2187 : 2048, which, being cut off from the major tone 9 : 8, left the interval called a limma, λεῖμμα, or minor semitone, in the ratio 256 : 243. Also, the interval 125 : 128 was called a major apotome, and 2025 : 2048 a minor apotome.

APOTROPÆ (from ἀποτρέπω, *I avert*), in *Ancient Poetry*, verses composed for averting the wrath of incensed deities; and the deities invoked for averting any threatened misfortune were called *Apotropaei*. They were also called *Alexicaci*, from ἀλέξω, *I drive away;* and *Averrunci*, from *averrunco*, which denotes the same.

APPALACHIAN MOUNTAINS. See Alleghany.

APPALACHICOLA, a river of Florida, North America, which is formed by the union of the rivers Flint and Chattahouchee, and falls into the Gulf of Mexico after a course of 70 miles. It is navigable for small craft throughout its course. On its banks is a small town of the same name, with a good harbour, and a considerable cotton-trade.

APPANAGE. See Apanage.

APPARATUS, a term used to denote a complete set of instruments, or other utensils, belonging to any artist or machine.—Apparatus is also used as a title of several books composed in the form of catalogues, bibliothecas, dictionaries, &c., for the conveniency of study.

APPAREILLE, in *Fortification*, the slope or ascent to a bastion.

APPARENT Heir, in *Law*. No inheritance can vest, nor can any person be the actual heir of another, till the ancestor is previously dead. *Nemo est hæres viventis*. Before that time the person who is next in the line of succession is called *heir apparent*, or *heir presumptive*. Heirs *apparent* are those whose right of inheritance is indefeasible, provided they outlive the ancestor; as the eldest son or his issue, who must by the course of the common law be heirs to the father whenever he happens to die. Heirs *presumptive* are those who, if the ancestor should die immediately, would in the present circumstances be his heirs, but whose right of inheritance may be defeated by the contingency of some nearer heir being born. In Scottish law, according to Erskine, he who is entitled to enter "heir to a deceased ancestor, is, before his actual entry, styled, both in our statutes and by writers, *apparent heir*, though that application is used sometimes in vulgar speech to denote an eldest son, even before his father's decease."

APPARITION, Circle of, in *Astronomy*, is that part of the heavens in any given latitude within which the stars are always visible, in contradistinction to the circle of occultation.

APPARITIONS.

An apparition may be defined a spectral illusion, involuntarily generated, by means of which figures or forms, not present to the actual sense, are nevertheless depictured with a vividness and intensity sufficient to create a temporary belief of their reality. It is the result of the re-action of an excited imagination, renovating past feeling or impressions, with an energy proportioned to the degree of excitement; arranging them often in new and fantastical groups; and thus surrounding us with a phantasmagoria of the bodiless creation of the brain, so distinct both in outline and lineament, that, while the exciting cause continues to operate, the illusion of reality predominates over the mind with an intensity generally equal to, sometimes greater than, that of the impressions produced by actual perceptions. But although the illusion thus generated is necessarily co-existent with the state of excitement in which it has its origin; or, in other words, ceases to be active when the spectral phenomena vanish; it does not therefore follow that the mind, when it regains its ordinary condition, becomes immediately sensible of the hallucination under which it has for a time been labouring, or capable of distinguishing between the perceptions of sense and the phantasms of imagination. On the contrary, observation proves, what theory equally sanctions, that the conviction of reality generally outlasts the impressions which originally produced it; and that, so far from any suspicion of illusion being entertained, or any power of discriminating the actual from the imaginary being evinced, this conviction takes entire possession of the mind, and, in many instances, maintains its hold with a firmness which all the force of argument and reason is insufficient to overcome. Hence the tenacity, and we may add the universality, of the belief in apparitions; and hence also the prodigious diversity of forms under which these spectral illusions are presented in the popular legends and superstitions of different ages and countries;—a diversity, in fact, which seems commensurate with the incredible variety of influences, whether morbific or other, by which the imagination may be excited, and past feelings or impressions vividly renovated in consequence of its reaction on the organs of sense.

But however this may be, every one must, we think, agree that the subject of apparitions, viewed in connection with the philosophy of the human mind, is one of no mean importance: and, as it has more or less engaged the attention of philosophers from the earliest times, a brief and condensed historical view of the various theories which have been formed to account for these illusions may prove neither uninteresting nor uninstructive; while, in a work of this nature, intended to form a record of the great mass of human knowledge, such an outline appears to be not only requisite, but altogether indispensable.

In the ancient systems of philosophy we meet with the most opposite and contradictory opinions on the subject of spiritual essences, as well as in regard to their supposed occasional manifestations to the eye of flesh and blood. Ocellus Lucanus, one of the earliest of the Greek philosophers whose works have come down to our times, attempts to account for the appearances of the universe by having recourse to eternity and the circle. The circle he conceived to be the appropriate representative of eternity, if not absolutely identical with it; and as form, time, motion, and substance are without beginning and without end, so the universe, of which these are but parts, cannot have been generated, and, for the same reason, must be incapable of corruption. It is in fact a circle, without beginning and without end. But this stupendous circle is divided into parts totally dissimilar, by an isthmus which our fanciful author has placed somewhere in the neighbourhood of the moon, and which forms the boundary between the residence of the gods, where all is invariable, and the material universe, where every thing is in a state of endless change and revolution; the fates having drawn this line of demarcation to separate the passible and corruptible part from that which is impassive and incorruptible, or, in other words, subject to neither motion nor change. The changes on this side of the isthmus, however, are, according to Ocellus, just as endless as the state of things beyond it is immutable; for these changes revolve in a circle, which has neither beginning nor end, and consequently must be eternal; and hence the only difference between the two unequal compartments is, that, in the one, every thing is in a state of eternal rest, while, in the other, all is motion and revolution without end. It seems to follow, therefore, that the fates, in tracing this line of demarcation, have excluded the gods from all control over the material or corruptible part of the universe; and that the existence of an immortal essence, in the midst of the confusion of our lower world, is wholly impossible. Yet, in his fourth book, Ocellus speaks of the Deity conferring instincts and appetites on man: and, in a fragment preserved by Stobæus, he says that life is that which holds the body together, and that the cause of life is the soul; that the world is held together by harmony, and that the cause of harmony is the Deity; that states are held together by agreement, and that the cause of this agreement is the law;—sentiments which seem strangely at variance with the transcendental doctrine of eternity and the circle, by which all the varied phenomena of the universe were to be explained.

The atomic theory of Democritus, which some have recently attempted to revive, was adopted with certain modifications by Epicurus, and has been explained and illustrated by Lucretius in his philosophical poem on the *Nature of Things;* in which he enters with ardour and enthusiasm into the views of his favourite master, assails his enemies with the bitterest invective, combats every objection and difficulty, palliates and mystifies what cannot be defended, and pours forth his whole genius in support of the system which Democritus imagined and Epicurus taught. But neither the numbers nor the ingenuity of the poet have succeeded in recommending to any rational mind a theory based on the most extravagant assumptions, and involving consequences subversive of all those checks and restraints by which society is held together. At the same time, Lucretius is the first ancient writer who makes a formal attack on the popular notions entertained respecting ghosts and apparitions. These he justly regards as complete illusions; and maintains, conformably to the philosophy of Democritus and Epicurus, that so far from being spirits returned from the mansions of the dead, they are nothing more than attenuated films, pellicles, or membranes, cast off from the surface of all bodies, like the *exuviæ* or sloughs of reptiles;[1] or, in other words, the mere shadows

[1] It is often amusing as well as instructive to trace the history and descent of opinions. The strange notion of Lucretius, that apparitions are subtile films or images rising from the surfaces of bodies, appears to have entered more or less into many of the systems

Apparitions.

of things which fear, and its offspring superstition, mistake for realities. The world, he observes, has long been in a state of horror and despair from dread of these incorporeal beings; and he acknowledges that his principal object, in expounding the doctrines of his master, is to rescue mankind from their vain apprehensions, by showing that all things are corporeal and dissoluble, not even excepting the soul itself; and thus destroying that *pneumatophobia* which, to use the language of Cudworth, makes men "have an irrational but desperate abhorrence from all spirits or incorporeal substances." Philosophy cannot certainly be better employed than in endeavouring to emancipate the mind from the unreal terrors by which it is so frequently enslaved. But it can scarcely fail to be a subject of regret that the philosophers of the Epicurean school should have sought to accomplish a laudable end by the intervention of means alike absurd and pernicious. Material necessity, and by consequence atheism, is at the root of all their doctrines; nor can these, therefore, be admitted to be true without overwhelming religion in the same ruin with superstition. Hence they are chargeable with the grievous fault of striking at a mass in order to reach an individual; of attempting to hew down the trunk in order to clear away a withered branch. At the same time they have the unquestionable merit of being the first who endeavoured, however unsuccessfully, to account, upon natural principles, for those appearances, which have in all ages more or less excited the fears and mingled with the superstitions of mankind.

But, without dwelling on particular systems of philosophy, we may observe generally, that although the belief in spectres or phantasms appears to be as old as the existence of the human race, this belief has in every instance been modified, and we may almost say regulated, by the prevalent pneumatological opinions respecting the soul, whether these have been derived from the writings of philosophers and poets, or imbibed from sources purely mythological. Strictly speaking, indeed, the character of superstitious credulity has been in all ages the same; but it is nevertheless true, that its particular objects have varied, as the opinions of mankind have changed respecting the sentient principle or cause of the vital phenomena.

In the case of the Greeks and Romans this is peculiarly remarkable; inasmuch as their superstitions afford ample evidence of the diversity of opinion that prevailed regarding the soul, yet are all more or less tinctured with its predominant colour and complexion. Democritus and Epicurus, as we have seen, considered it corporeal, but differed widely as to its substance; the Stoics maintained that it was ignited air; Hippo held that it was water; and Heraclitus was of opinion that, as the *anima mundi*, or soul of the world, was a vapour or exhalation from the moist elements, so the souls of animals were vapours or exhalations from their own bodies, or something external. Of those, again, who believed the soul to be incorporeal, some maintained that it was a substance, and immortal, while others asserted that it was neither. Thales taught that it was always in motion, and itself the origin or cause of that motion; Pythagoras regarded it as a self-moving monad or number; Plato thought it a substance conceivable only by the understanding, and moving according to harmony and number; Aristotle described it as the first *entelecheia*, or, to use the language of the translator of Nemesius, "the first continuall-motion of a bodie-naturall, having in it those instrumental parts, wherein was possibility of life;" and Dinarchus considered it a harmony of heat, cold, moisture, and dryness, or, in other words, a contradiction. Some imagined that there is but one universal soul, distributed in portions throughout all bodies, animate and inanimate, which doctrine was subsequently adopted by the Manicheans; while others taught that there is indeed one universal soul, but at the same time many different species. The illustrious head of the Platonic school seems to have believed in the existence of an universal soul, by means of which all things were supported in being; but he conceived that those only were to be accounted living creatures which had separate souls. The doctrine of transmigration was a natural consequence of these opinions, and, what is not a little remarkable, it seems to have been generally received among those philosophers who believed most firmly in the immortality of the soul; some making it pass indiscriminately into the bodies of plants and animals; others, into all organized structures; while a third set, conceiving that every kind of soul, whether rational or irrational, has a structure exactly suited to its own faculties and no other, confined it to structures of the same species. Plato distinguished these faculties into three classes, the vegetative, sensitive, and rational; and assigned a separate residence to each, the habitation of the last being, according to him, in the head.

Indeed the practice of arranging the logical entities, known by the names of *powers*, *faculties*, or *functions*, into different classes, and ascribing them to different species of souls, appears to have been prevalent at an early period, both among philosophers and poets. Empedocles allotted a rational and a sensitive soul to every animal; the rational one being derived from the gods, and the sentient a product of the four elements. But the ancients generally reserved the rational soul for man. In Homer's time the soul was divided into two species, the φρην and the θυμος, but afterwards, according to Diogenes Laertius, into three; while the body was considered tripartite, being composed of a mortal or crustaceous part,—a divine, ethereal, or luciform portion, appropriated to the φρην,—and an aerial, misty, or vaporous part, allotted to the θυμος. After the dissolution of the mortal part, however, the φρην was entirely separated from the θυμος, and a different habitation assigned to each. Hence we learn from Homer, that the φρην of Hercules was actually feasting with the gods, and making love to Hebe, at the very time that Ulysses was conversing with his θυμος in Hades. Similar notions were entertained by the Roman poets. According to them, every man possessed a threefold soul, which, after the dissolution of the body, resolved itself into the *Manes*, the *Anima* or *Spiritus*, and the *Umbra*, to each of which a different place was assigned. The Manes descended into the infernal regions, to inhabit

on the same subject taught by the schoolmen in the middle ages, although the latter have not always remembered to acknowledge their obligations to the Roman poet. A similar view may also be detected in the reveries of the sympathetic philosophers, and particularly in the theory of the transmission of spirits propounded by Lavater; nor are there wanting traces of its existence in the popular superstitions both of ancient and modern times. Some of the older philosophers, on the other hand, appear to have construed the Epicurean doctrine of corporeal images much more literally than its great poetical expounder seems to have intended. Psellus, for instance, stoutly contends for the heretical doctrine of the materiality of demons, in which he seems to have been a stanch believer. Paracelsus, conceiving that the elements were inhabited by four kinds of demons—spirits, nymphs, pigmies, and salamanders—argues, in like manner, for the materiality of these non-descript beings, but seems inclined to think that they possessed *caro non-adamica*, which may easily be conceded to him. Cudworth maintains the materiality of angels; and some of his successors, improving upon their models, contend for the materiality of every thing in heaven above or in the earth beneath; thus completing the cycle of absurdity, and bringing us back at last to the Epicurean doctrine, from which we set out.

either Tartarus or Elysium; the Anima ascended to the skies, to mingle with the gods; while the Umbra hovered around the tomb, as if unwilling to quit its connection with the body, of which it was the *wraith* or shadow. Hence Virgil represents Dido, when about to expire, as threatening to haunt Æneas with her *umbra*, at the same time consoling herself with the expectation that the tidings of his punishment will reach her *manes* in the shades below.[1] Nor are there wanting traces of an analogous belief in the popular superstitions of modern times. It is an article of ghostly faith, that apparitions are frequently seen near the spot where the gross or crustaceous body lies, waiting either until that body be interred, or until some crime be confessed and expiated; and, if tradition may be in aught believed, the spectral appearances of individuals have occasionally been observed previous to their death, of which, indeed, these illusions are the sure forerunners or harbingers. Among the Greeks such spectres were denominated φαντασματα, πνευματα, ειδωλα, apparitions, aerial forms, likenesses; while the Romans called them *spectra, umbræ, simulacra, manes, imagines*, visions, shades, similitudes, ghosts, and images.

Some, however, thought that spectral illusions were souls visibly expanded; but others doubted whether they were ψυχαι, the principles of life, or merely the vehicles of such principles. The ghost of Hercules, which Ulysses saw in Hades, was, according to Homer, his ψυχη and ειδωλον, or his corporeal likeness, animated by his θυμος; and such *simulacra* were supposed to speak, to complain, to feel hunger, and to receive nourishment, though probably at that table only where spare fast diets with the gods. It may also be observed, that, according to Virgil, the *umbræ* were the *animæ* or souls themselves, and were all sprung from the same source as the soul of the universe, namely, from ether or elemental fire. Hence, the *umbræ* which Æneas beheld in the shades below, when he went thither to visit his father Anchises, were ethereal souls, receiving rewards or suffering punishments for their past deeds; some for inexpiable crimes, which rendered their punishments eternal; others for offences, the stains of which might be obliterated, and who, consequently, were exposed for a series of ages to the action of air, water, or fire, " until the crimes done in their days of nature were burned and purged away." At the same time, it is quite true, as Dr Barclay has remarked, that " in most, if not in all of these *simulacra*, the dress and its fashions were represented as well as the body; while, in all the poetical regions of the dead, chariots and various species of armour were honoured likewise with their separate *simulacra;* so that these regions, as appears from the *Odyssey, Æneid*, and *Edda*, were just the *simulacra* of the manners, opinions, customs, and fashions, that characterized the times and countries in which their poetical historians flourished."[2]

To the superstitions of Greece and Rome we are also indebted for those subordinate spirits named *demons* or *genii*, who for many centuries were the subject of numberless spectral illusions. These intermediate beings were distinguished by the Platonists from the superior deities of the popular mythology on the one hand, and from heroes or demigods on the other. They were divided into beneficent and malignant spirits; and, according to the conceptions of the Platonic philosophers, differed in no material degree from the good and evil angels of the Christian belief. Socrates fancied himself constantly attended by a demon or genius, to whose inspirations or suggestions he conceived himself indebted for those views of practical wisdom and philosophy which have rendered his name so deservedly illustrious. Among the Romans, again, genii were supposed to be messengers of the gods, employed, on particular occasions, to give intimation to men of approaching events, or calamities soon to befall them. Of this kind was the phantasm which appeared to Brutus sitting dejected in his tent, and told him that they would meet again at Philippi.[3] Cornelius Sylla received a similar intimation from an apparition, which accosted him by his name: and, concluding that his death was at hand, the ex-dictator prepared himself for the event, which took place the following evening, in consequence of a sudden and violent attack of fever. Cassius Severus, the poet, a short time before he was slain by order of Augustus, saw, during the night, a human form of gigantic size, with his skin black, his countenance squalid, his beard grizzled, and his hair dishevelled; a phantasm not unlike the evil genius so powerfully described by Lord Byron as appearing to Manfred in the hour of his agony.[4] The emperor Julian, on

[1] This notion of a threefold soul is well expressed in the following lines, attributed to Ovid:—

> Bis duo sunt homini: *Manes, Caro, Spiritus, Umbra:*
> Quatuor ista loci bis duo suscipiunt;
> Terra tegit *Carnem*, tumulum circumvolat *Umbra*,
> Orcus habet *Manes, Spiritus* astra petit.

[2] *Inquiry into the Opinions, ancient and modern, concerning Life and Organization*, p. 14. By John Barclay, M. D. Edinb. 1822, 8vo.

[3] The observations of Sir Walter Scott on the spectre which appeared to Brutus on the eve of the battle of Philippi are equally just and philosophical, in so far as regards the exciting cause:—" The anticipation of a dubious battle, with all the doubt and uncertainty of its event, and the conviction that it must involve his own fate, and that of his country, was powerful enough to conjure up to the anxious eye of Brutus the spectre of his murdered friend Cæsar, respecting whose death he perhaps thought himself less justified than at the Ides of March, since, instead of having achieved the freedom of Rome, the event had only been the renewal of civil wars, and the issue might appear most likely to conclude in the total subjection of liberty. It is not miraculous that the masculine spirit of Marcus Brutus, surrounded by darkness and solitude, distracted probably by the recollection of the kindness and favour of the great individual whom he had put to death to avenge the wrongs of his country, though by the slaughter of his own friend, should at length place before his eyes in person the appearance which termed itself his evil genius, and promised again to meet him at Philippi. Brutus' own intentions, and his knowledge of the military art, had probably long since assured him that the decision of the civil war must take place at or near that place; and allowing that his own imagination supplied that part of his dialogue with the spectre, there is nothing else which might not be fashioned in a vivid dream or a waking reverie, approaching, in absorbing and engrossing character, the usual matter of which dreams consist. That Brutus, well acquainted with the opinions of the Platonists, should be disposed to receive without doubt the idea that he had seen a real apparition, and was not likely to scrutinize very minutely the supposed vision, may be naturally conceived; and it was also natural to think, that although no one saw the figure but himself, his contemporaries were little disposed to examine the testimony of a man so eminent, by the strict rules of cross-examination and conflicting evidence, which they might have thought applicable to another person and a less dignified occasion." (*Demonology and Witchcraft*, p. 10, 11.)

[4] The description alluded to in the text is as follows:—

> I see a dusk and awful figure rise
> Like an infernal god from out the earth;
> His face wrapt in a mantle, and his form
> Robed as with angry clouds; he stands between
> Thyself and me, but I do fear him not.

one occasion, while engaged in an expedition, beheld a spectre or apparition clad in rags, yet bearing in its hands a horn of plenty, covered with a linen cloth; and thus emblematically attired, the spirit stalked mournfully past the hangings of the Apostate's tent. Lastly, Dio of Syracuse was visited by one of the Furies in person, not in the shape of a vixen, but of a horrid phantasm, the appearance of which was considered by the soothsayers indicative of the death of his son (which occurred soon after), as well as of his own approaching dissolution. Many other instances might be given of similar illusions, evidently conjured up by the workings of an excited imagination re-acting on the organs of sense, and believed to be harbingers of "coming events;" but those we have mentioned are sufficient to show the opinions entertained in regard to such apparitions, and to exemplify the power which superstition exercises over the mind when unenlightened by a sound and rational philosophy. We may add, however, that demons or genii were frequently regarded as private monitors, who by their insinuations disposed each man to good or evil actions, and were not only reporters of his crimes in this life, but registrars of them against his trials in the next; an opinion which the Romans evidently derived from the Greeks, among whom a similar notion prevailed from an early period of their history.

Among the Jews and early Christians we find analogous superstitions, though, as might have been expected, much more varied and complex in their details. Like the Greeks and Romans, the Jews believed in good and evil spirits, to the latter of which the name of demons came to be exclusively appropriated; and this belief they founded partly on the statements contained in their own Scriptures, partly on notions derived from the Pagans. Some of their angels were supposed to be created out of the elements of fire, others out of the wind; and both classes forfeited their immortality whenever they issued from their allotted place. Their business was to instruct mankind in wisdom and knowledge; and every thing in the world was conceived to be under their government. Even to the herbs of the field, supposed to exceed twenty thousand in number, presiding angels were assigned; and rain, hail, thunder, lightning, fire, fishes, reptiles, animals, men, cities, empires, nations, were all respectively under the dominion of spiritual powers. Nor were their demons less numerous than their tutelar genii or angels, as any one may easily satisfy himself by consulting the Talmud, in which this multitudinous array of spirits is very minutely described. Every form of evil, whether physical or moral, was ascribed to the direct agency of one or other of this subordinate tribe of devils, whose sole business it was to work mischief, and who were also conceived to be indefatigable in the exercise of their calling; so much so that, in the constant warfare carried on between the good and evil spirits, it is far from being clear that the former had always the advantage. Demoniacal possession is only one form under which this infernal agency manifested itself. In a word, the superstitious Jew who devoutly believed in the wild vagaries engendered by the seething imaginations of the Rabbin, might have said with the Roman satirist, *Nostra regio tam plena est numinibus, ut facilius possis deum quam hominem invenire.*

It is not to be wondered at, however much it may be regretted, that many of these notions accompanied the spreading of the gospel, and communicated a taint of Jewish superstition to the faith of the first Christians. The mind is unable at once to emancipate itself from the dominion of delusions, which have been consecrated by time and sanctioned by authority, and which, insensibly imbibed by education and habit, address themselves to the natural fears and feelings of the human heart. Hence it ought not to surprise us that, not only at the commencement of the Christian dispensation, but during a very long period afterwards, evident traces may be discovered of the prevalence of the popular opinion mentioned by Symmachus, namely, "that the Divine Being had distributed to cities various guardians, and that as souls were communicated to infants at their birth, so particular tutelary spirits were assigned to particular societies of men." On the other hand, some sects, puzzled to account for the origin of evil, and affecting philosophy without possessing a philosophical spirit, systematized the Jewish superstitions, by combining them with the creed of Zoroaster, and promulgating formally the doctrine of a ceaseless antagonism between the good and evil principles, personified in the Ormusd and Ahriman of the Persian mythology; while others, again, imitating the classification of the different orders of spirits by Plato, attempted a similar arrangement with respect to the hierarchy of angels.[1] Both systems involved the constant agency of spiritual power in the government of the world, and admitted also its occasional manifestation in the shape of apparitions. Among the Fathers, however, great diversity of opinion prevailed in regard to these illusions, which no one seems to have dreamt of attempting to explain by reference to natural causes. Origen, for example, conceived that souls, tainted with the guilt of flagrant crimes, and not purged from their impurity, were either confined in a species of limbo, or attached to particular spots, where, within certain limits, they might ramble about at will. Athanasius maintained that souls, when they were once released from their bodies, held no more communion with mortal men; and the more rational of the early theologians condemned all visions and apparitions that had not the unequivocal sanction of the Deity, our Saviour, or the angels. Augustin also remarked that, if souls did actually walk and visit their friends, he was convinced his mother, who had followed him by land and sea, would have shown herself to him, in order to inform him what she had learned in another state, as well as to give him much useful advice Others, however, yielded to the current superstitions, which they laboured to reconcile with the doctrines and statements of Holy Writ.

But it was not until a much later period of Christianity that more decided doctrines were established relative to the origin and nature of demons; and it is principally to the Papal Church of Rome that the unenviable honour is due, of adopting and methodizing the vagaries of the Pagans, as well as the legends of the Talmud, and thus originating that system of demonology which, from various causes, grew to such a monstrous height during the middle ages, as completely to overwhelm Christianity under its revolting and abominable fictions. When this church recognised the doctrine, that the functions of ministering angels were assigned to the spirits of departed saints, she opened a door for the admission of the abominations of Paganism in a new form,[2] and the encouragement of su-

[1] We allude to the Gnostics, according to whom the gradations in the hierarchy of angels stood thus:—The first and highest order was named seraphim, and the second cherubim; the third was the order of thrones, and the fourth that of dominions; the fifth was the order of virtues, the sixth of powers, the seventh of principalities, the eighth of archangels, and the ninth or lowest that of angels. This fable, as Dr Hibbert remarks, was pointedly censured by the apostles; yet, nevertheless, it outlived the pneumatologists of the middle ages, and is scarcely even now exploded.

[2] It is impossible not to feel that the reproaches which Reginald Scot casts upon the church of Rome, on account of her heathenism, are well merited, and that their chief bitterness is not so much in the unrelenting irony of that dauntless writer, as in

Apparitions.

perstitions, utterly subversive of all true religion; while, on the other hand, by countenancing and fostering the frantic extravagances of the demonologists, more particularly in regard to the impossible crime of witchcraft, she did all in her power to perpetuate the empire of delusion, and at the same time made herself responsible for the multiplied atrocities which were committed under its influence. She became, in fact, the nursing mother of lies, and the avowed patroness of the powers of darkness. The devil and his legions were everywhere and in every thing: diabolical agency was supposed to be unremitting and universal. The priests strengthened their dominion by practising conjurations and exorcisms; while the monks fabricated legends suited to the prevailing taste, and calculated to thicken the delusion which added so greatly to their spiritual power. In the meanwhile Satan's invisible world was displayed with a topographical minuteness of detail, which could scarcely have proved very agreeable to that great personage. The nature, history, and rank of devils were curiously inquired into, and the point of precedency in the infernal hierarchy settled to a nicety; the various forms assumed by them in the course of their operations upon earth were also very fully described; the different tests by which their presence might be detected were given with something like scientific precision; and, what is still more extraordinary, the number of these fallen spirits was determined to a fraction. In short, the wildest fictions which imagination ever coined were gravely received as matters of faith and doctrine; while a new impulse and direction were thereby given to popular superstition, which the ghostly legends of the Church had far outstripped in point of extravagance.

At this period, accordingly, the belief in apparitions was universal, and people would have sooner doubted their own existence or identity, than ventured to call in question the most grotesque fooleries which the human fancy ever imagined. Even the Reformation, which overthrew so many errors, eradicated so many prejudices, and destroyed so many delusions, left this one as hideous as ever. And so far from proving himself superior to the vain imaginations and follies of his time, Martin Luther has left abundant evidence to show, that he was as deeply imbued with superstitious credulity, and believed as firmly in diabolical apparitions, as the most illiterate monk in the church which he shook to its very foundations. He even fancied that the devil took a particular pleasure in annoying him, doubtless from pique at the successful resistance he had opposed to the power and pretensions of Rome; and he relates several conversations, or rather altercations, he had had with the Evil One, in which, by his own showing, the reformer had clearly the best of it (so far at least as abuse was concerned), and generally ended by putting the fallen spirit to flight. On one occasion in particular, when the Tempter had intruded himself rather unseasonably, and had chosen to assume "a glorious form of our Saviour Christ," the reformer, who at first expected a revelation, lost all temper as soon as he discovered the real character of his visitant, and exclaimed fiercely, "Away, thou confounded devil; I know no other Christ than he that was crucified, and who, in his word, is pictured and preached unto me; whereupon," he adds, "the image vanished, which was *the very Devil himself*." And all his narratives of losses or misfortunes which happened to individuals in whom he felt an interest commonly end with the pithy solution, "This did the devil."[1] Nor was he at all singular in entertaining these notions, which in fact were equally shared by the other reformers, and continued long afterwards to exert a most powerful influence upon the faith of all Europe; particularly in regard to the imaginary crime of witchcraft, for which so many unhappy wretches suffered death both in this and in other countries.

It would be vain to inquire whether, at the period in question, or indeed for a long time afterwards, any attempt was made to expose the impostures which were continually practised, or to account, upon rational principles, for those spectral illusions which are known to be generated in particular states of the body and mind. Such an idea seems never to have entered the head of any one; and indeed if a sceptic had arisen bold enough to insinuate even a suspicion of the fallacy of the received opinions, he would have been sacrificed without mercy to the bloody Moloch, who was then the object of almost universal homage. He might perhaps have denied his God, and blasphemed his Saviour with impunity; but if he had dared to dispute the agency of the Devil, to doubt the reality of his appearances, or in any manner of way to assail the creed of the

---

their truth. "Surelie," says he, "there were in the Popish church more of these antichristian gods in number, more in common, more private, more publicke, more for lewd purposes, and more for no purpose, than among all the heathen, either heretofore or at this present time; for I dare undertake, that for everie heathen idol I might pronounce twenty out of the Popish church. For there were proper idols of every nation, as St George on horseback for England, St Andrew for Burgundie and Scotland, St Michael for France, St James for Spain, St Patrike for Ireland, St Davie for Wales, St Peter for Rome and some part of Italie. Had not every citie in all the Pope's dominions his severall patrone; as Paule for London, Denis for Paris, Ambrose for Millen (Milan), Louen for Gaunt, Romball for Mackline, St Mark's Lion for Venice, the three magician kings for Cullen, and so of other? Yea, had they not for everie small towne and everie village and parish (the names whereof I am not at liberty to repeat) a severall idol: as St Sepulchre for one, St Bride for another; St All Hallowes, All Saints, and Our Ladie for all at once? Had they not hee idols and shee idols, some for men, some for women, some for beasts, and some for fowels? And do you not thinke that St Martine might be opposed to Bacchus? If St Martine be too weak, we have St Urbane, St Clement, and manie others to assist him. Was Venus and Meretrix an advocate for whores among the Gentiles? Behold, there were in the Romish church to encounter them, St Aphra, St Aphrodite, and St Maudline. Was there such a traitor among the heathen idols as St Thomas Becket? or such a whore as St Bridget? I warrant you, St Hugh was as good a huntsman as Anubis. Was Vulcane the protector of the heathen smithes? Yea, forsooth, and St Euloge was patron for ours. Our painters had Luke, our weavers had Steven, our millars had Arnold, our potters had St Gore with a devil on his shoulders and a pot in his hand. Was there a better horseleech among the gods of the Gentiles than St Loy? or a better sow-gelder than St Anthonie? or a better tooth-drawer than St Apolline? I believe that Apollo Parnopeius was no better a rat-catcher than St Gertrude, who hath the Pope's patent and commendation therefore." And so honest Reginald proceeds with his expostulatory comparison, which, in the true spirit of his age (when the phantasms of demonology maintained their dominion even over those minds which had cast off the fetters of the church of Rome), he concludes by declaring that "all these antichristian gods, otherwise called popish devils, are as rank devils" as any that are spoken of in the Psalms, or mentioned in other parts of Scripture. (See *Discourse on Devils and Spirits*, appended to the *Discourse of Witchcraft*.)

[1] Mr Coleridge, in his *Friend*, vol. ii. p. 336, gives the following natural and rational account of the origin of Luther's visions:— "Had Luther been himself a prince, he could not have desired better treatment than he received during his eight months' stay in the Wartzburg: and in consequence of a more luxurious diet than he had been accustomed to, he was plagued with temptations both from the 'flesh and the devil.' It is evident from his letters that he suffered under great irritability of his nervous system, the common effect of deranged digestion in men of sedentary habits, who are at the same time intense thinkers; and this irritability adding to and vivifying the impressions made upon him in early life, and fostered by the theological systems of his manhood, is abundantly sufficient to explain all his apparitions, and all his mighty combats with evil spirits."

Apparitions.

demonologists, it would have been better for him that a mill-stone had been hanged about his neck, and he had been cast into the midst of the sea. On the gibbet or at the stake, he would infallibly have expiated the audacity of his unbelief. In process of time, however, humanity began to lift up her voice, and reason seemed to recover from the long trance into which the reign of delusion had thrown her. Scattered rays of light broke in from various quarters; as knowledge advanced, the mind became expanded; a spirit of inquiry was gradually developed; the learned began to reason and to doubt; and the empire of superstition was shaken. For long, the vulgar creed, which had been deeply tinged with the monstrosities and follies we have alluded to, resisted the influence of the causes which were now at work, sapping the foundations of the whole edifice of delusion; and even yet, amidst all the light with which we are surrounded, some corners of the world still remain unilluminated. But a change had come over the spirit of the dream in which the nations had so long been entranced; and men, having begun to examine, soon learned to doubt and disbelieve.

About the end of the sixteenth and beginning of the seventeenth century, various theories were suggested to account for those extasies of imagination in which spectral illusions have their origin; and, in the memorable experiment of palingenesis, or the resurrection of plants (a secret known to Digby, Kircher, Schot, Gafferel, Vallemont, and others), an explanation was sought of apparitions, which were thought to be reproduced in a similar manner. To this succeeded the doctrine of astral spirits, as they were called; which was an attempt to combine the metaphysical opinions then entertained respecting ideas, with the conclusions deduced from the experiment of palingenesis, or the reproduction of a rose, like the phenix from its ashes. Others, again, referred all the phenomena of extasies, hallucinations, and apparitions to the phantasy or imagination, which was justly conceived to exert a powerful influence over the mind, and to be primarily concerned in the production of those illusions which give birth to a belief in apparitions. Van Helmont, Hoffmann, and most of the medical inquirers of that age, adopted this explanation; and several passages in Hamlet show that such was also the belief entertained by our immortal dramatist. If the imagination, it was argued, can induce a particular form or mark upon the fœtus in the womb, much more must it be capable of vivifying and clothing ideas in the mind so as to create an illusion of reality. Nor were these inquiries confined to apparitions alone. In the year 1701 the celebrated Thomasius distinguished himself by an inaugural dissertation *De Crimine Magiæ*, in which he attacked, with irresistible force of reasoning, the prevalent belief in witchcraft, and boldly exposed the insane and murderous delusions which had conducted whole hecatombs of victims to the stake. This thesis, embodying a formal attack on demonology, was publicly read in the university of Halle, which, to its honour, greeted with applause the bold scepticism of the young jurisconsult; and so well did the latter perform his task, that his juvenile production is still considered valuable, both for its facts and its reasonings.

The approbation with which the inaugural dissertation of Thomasius was at first received, and the merited celebrity which it subsequently obtained, may be considered as proofs that more rational opinions had already begun to prevail, at least among the learned; and that the minds of men were in some measure prepared for the reception of the new doctrines he so fearlessly promulgated. Popular credulity, indeed, still continued gaping and greedy: it still yearned, with an unabated craving, for the supernatural and the diabolical. But the softening and humanizing influence of knowledge had imperceptibly mitigated the ferocity which the belief in demonology had originally inspired; and, although the public generally were not more enlightened or less superstitious, the magistrate had insensibly become more humane, and the fires of persecution burned less frequently and fiercely. The tide, in short, had obviously turned; and the first indication of the reflux is afforded by the justly-celebrated discourse in question.

At the same time, Thomasius, though among the foremost, was not the first, to assail demonology. This honour of right belongs to Dr Balthasar Bekker,[1] a protestant clergyman at Amsterdam, and author of a learned

[1] Balthasar Bekker was a native of Metselawier in Friesland, where he was born in the year 1634. He had no other master than his father, who was the pastor or clergyman of the place, until he attained the age of sixteen, when he went to prosecute his studies at Groningen, and afterwards at Franeker. In the first of these universities Alting was his master in Hebrew, and conceived a strong affection for his pupil, whom he subsequently supported against his numerous enemies and persecutors. Having completed his studies at Franeker, Bekker was appointed rector of a Latin school, and afterwards pastor at Ooterlitten, where he signalized himself by his zeal in the discharge of his duty, and in consequence drew down upon himself the enmity of his less active colleagues. In 1666 he took the degree of Doctor of Divinity at Franeker, together with the situation of pastor, and soon afterwards published a tract entitled *De Philosophia Cartesiana Admonitio Sincera*, in which he attempted to prove that the Cartesian philosophy, a taste for which he was anxious to diffuse, might be easily allied with the study of theology. This piece appears to have procured him nothing but enemies, the number of whom was considerably increased by the publication, about the same period, of two catechisms, under the absurd titles of *Gesneden Brood* and *Vaste Spyze*; in the last of which he advanced some peculiar opinions concerning the state of Adam before his fall, the nature and duration of the pains of hell, the ecclesiastical hierarchy, and the rights of ecclesiastical assemblies. His jealous colleagues accused him of Socinianism and Cartesianism; and although he wrote a defence of his opinions, and showed a disposition to alter or retract every thing that might be conceived contrary to the faith, the synod, disregarding his concessions, prohibited the printing of the *Vaste Spyze* under a severe pecuniary penalty. Chagrined at this proceeding, he quitted Franeker, and became successively pastor at Loenen and Wesop, chaplain of a regiment of the line, and finally, in 1679 established himself at Amsterdam, where new writings soon kindled up afresh the animosity of his brethren. He combated the prejudices of the vulgar in a tract which he published on the occasion of the appearance of a comet in 1680 and 1681; and, in his *Recherches sur les Comètes*, published in 1683, he adopted a course of argument similar to that pursued by Bayle, showing that comets are neither presages nor forerunners of calamities, as was then currently believed, and ridiculing the popular notions and superstitions on this subject. This little work, replete with sound and just ideas, was well received. But a very different fate awaited another and far more important one, which he published soon after, under the title of *De Betooverde Wereld*, or *The World Bewitched*; a performance which justly entitles him to be ranked with the freest, boldest, and most philosophical thinkers which any age or country has produced. *De Betooverde Wereld* was first printed at Franeker, and afterwards reprinted several times at Amsterdam, where a French translation, in four volumes 12mo, appeared in 1694; and a new edition was published at Deventer so late as the year 1737. This work, which had the misfortune to appear too soon, is the one which has most contributed to render Bekker's name famous, both from its own intrinsic merits, and from the fury of calumny and persecution to which it exposed him. If formerly he was regarded as a Cartesian and Socinian, he was now denounced as a downright Sadducee. All pens were in motion against him; and before Bekker had time to reply to the host of adversaries by whom he was assailed, his book was submitted to the censure of the ecclesiastical council. The author published a defence or apology, *Schriftelike Satisfactie*, in which he protested against all malignant interpretations of his book, and avowed his belief in the existence of the devil, but at the same time expressed his conviction that

work, first published in Dutch and afterwards in French entitled, *The World Bewitched, or an Examination of the Common Opinions concerning Spirits, their Nature, their Administration, and their Operations, and also concerning the Effects which Men are capable of producing by their Intercourse and their Virtue:* a work which Thomasius must in all probability have seen and consulted, as the French edition appeared in 1694, ten years prior to the publication of his thesis; and the persecution which the author experienced on account of his scepticism about devils and their supposed operations could scarcely fail to make it generally known. But be this as it may, the performance of the Dutchman is certainly an extraordinary one for the time at which it appeared; being not more remarkable for the learning it displays than for the boldness with which it combats the received opinions regarding spirits, and the exceeding ingenuity with which the various frauds and impostures of the demonologists are detected and exposed.

The author sets out by giving an able and accurate exposition of the opinions, or rather fables, of the Pagans, Jews, and Mahometans, on the subject of demons, or good and evil spirits, with their supposed attributes, functions, and operations, as described in their different mythological systems, and particularly as received at the period when Christianity was first preached to the world. He then proceeds to show that the early Christians insensibly introduced and mixed up with the new faith many of the fictions of Paganism and Judaism; and that this corrupting process went on continually increasing, until it attained a maximum under the Papacy, when all the miracles which the Pagans had supposed to have been performed by their demons or inferior divinities were ascribed to angels, to the souls of sinful men, and, above all, to the power of the devil. In particular, he traces the progress of Manicheism, from the time when it first assumed consistency and form; and shows, in a very striking manner, how this heresy, though anathematized by the Church, gradually insinuated itself into the very core of all her doctrines respecting spiritual agency in human affairs; and thus became part and parcel of the creed which she ordained men to believe under the penalty of eternal damnation. It is to this unfortunate intermixture of Paganism with Christianity, therefore, that he ascribes all the abominations with which the latter was polluted; and hence he contends, " que plus on se trouve éloigné du Paganisme, soit pour le temps, soit pour les lieux, moins on ajoute de foi à toutes les choses qui regardent le diable et son pouvoir." But his great principle is, that the doctrines of the demonologists are not more repugnant to reason, than adverse to Scripture when rationally interpreted. Revelation, he holds, contains nothing to sanction such doctrines; and he supports this opinion by a detailed examination of all the cases mentioned in holy writ where the devil is either represented as appearing to men, or exercising an immediate power over their bodies or minds,—explaining them on rational or natural principles with singular skill and ingenuity. For example, he rejects as absurd the idea of demoniacal possession, though generally received by the Protestant as well as the Catholic Church; and regards the cases of *dæmonia* mentioned in the New Testament as not properly " une expulsion des diables, mais une guérison miraculeuse de maladies incurables." Again, with regard to the metaphysical doctrine of the demonologists, " qu'un esprit en tant qu'esprit, et d'autant plus même qu'il est un esprit, peut sans corps agir sur toutes sortes de corps et sur les autres esprits," he does not meet it by a direct denial, but calls upon his adversaries to prove their own fundamental proposition. " Je demande des preuves de cette thèse," says he, in his *Abrégé* and *Défense;* " et parce que cette demande est imprévue et extraordinaire, et sur laquelle par conséquent on ne s'étoit préparé, on prend ma demande pour une négative.—I do not deny the truth of it, if it be true, but neither can I admit the truth of it till it be proved, nor can you assume it without proof, and then call upon others to believe it." Upon the same principle he demonstrates the utter absurdity of all supposed compacts with the devil, which he considers as not more impossible in themselves than incapable " subsister, en aucune manière, avec ce qui est contenue dans la doctrine de l'Ecriture, ni avec l'économie de l'alliance de Dieu, tant avant la Loi que sous la Loi, et moins encore sous l'Evangile."

But the most interesting part of this curious work, perhaps, is that where the author exposes, with equal skill and severity, the various frauds and impostures which have been practised upon ignorant credulity, and have thus given rise to all the delusions of witchcraft, and to a vast majority of those on the subject of apparitions. He examines in detail a great number of cases of both descriptions, and never fails to detect and drag to light the deception in which they originated. He exhibits a commerce of imposture and dupery, of fraud and credulity, often amusing, always instructive, sometimes truly horrible with reference to its consequences. In short, his exposure is complete and triumphant. " Les diables qui se faisoient voir et entendre," says he, " étoient dans la cervelle des hommes; si non, ils étoient faits de chair et d'os;" and he holds, " qu'il n'y auroit point du tout de sorcellerie, si l'on ne croyoit pas qu'il y en eust." But this being once believed, and the magistrate having set himself to punish an imaginary and impossible crime, the belief became stronger as the fires of persecution grew hotter, and each new holocaust only prepared fresh victims for the

Satan was chained in the bottom of hell, and consequently prevented from intermeddling with human affairs. The council had the good sense to be satisfied with this explanation; but the clergy of Holland, irritated at the indulgence shown to Bekker, overwhelmed it with reclamations, and forced it, by dint of clamour, to examine the affair more seriously. Bekker then demanded that the matter should be carried before the synod, and presented a new defence of his opinions; but the synod condemned the work, and deposed the author from his ministerial charge. This judgment was received with a sort of triumph by the clergy, and attacked by some of the author's friends in a clever tract, entitled, *Le Diable Triomphant, parlant sur le Mont Parnasse.* The synod, however, adhered to its sentence, and Bekker died of a pleurisy in 1698, without having been reinstated in his charge. On the occasion of his deposition, his enemies caused a medal to be struck, representing the devil dressed in clerical costume, and mounted upon an ass, with a sort of banner in his hand, emblematical of the triumph which the clergy had obtained in the synod. But this triumph was short-lived; for although the synod declared to a man in favour of the devil, the rational part of the world were ultimately convinced by the reasonings of the deposed minister; which soon began to gain ground, and contributed largely to emancipate the minds of men from the thraldom of a bloody and debasing superstition. Bekker, it seems, though a profound theologian and an able scholar, was a very ugly man, with bandy legs, and a nose and chin so prominent that they almost met; peculiarities which gave rise to the following epigram of Lamonnoye, prefixed to some of the French editions of *The World Bewitched:*—

Oui, par toi de Satan la puissance est brisée;
Mais tu n'as cependant pas encore assez fait;
Pour nous ôter du Diable entièrement l'idée,
Bekker, supprime ton portrait.

sacrifice. Dr Bekker concludes his remarkable work in these words:—"Si les souverains et les magistrats punissoient aussi exactement ceux qui accusent les autres de magie, qu'il y en a qui sont prestes à punir ceux qui sont accusés, lesquels ils jettent à la première délation dans les fers, et qu'ils donnassent la question seulement la moitié aussi forte aux délateurs, pour donner des preuves de leurs accusation, qu'ils la donnent à ceux-là pour confesser, je suis certain qu'ils n'auroient pas beaucoup besoin de bois pour les bruler. Car quoique dans le commencement ils eussent beaucoup à faire avant que cette nouvelle manière de plaider fust venue à leur connoissance, cela ne laisseroit pas de se passer bientost, lorsqu'ils verroient, qu'en accusant, ils se mettroient dans l'obligation de prouver ce qu'ils avanceroient, ou de subir la peine de la faute, en cas qu'ils ne peussent la prouver." Whoever takes the trouble to read the records of our own criminal procedure, and to observe the nature of the evidence upon which persons accused of witchcraft and sorcery were "fylit, convict, and brynt," will probably be convinced that these records would have been disgraced by few such atrocities had Dr Bekker's principle been adopted and acted upon. But a different form of practice was followed, of which it may with literal truth be said, *Siquidem accusâsse hic sufficit, quis insons habebitur?*[1]

Upon the whole, it is impossible not to regard the production of the Dutch divine as in many respects one of the most remarkable extant, considering the time when it appeared; nor are we aware of any similar instance of a writer who so far outstripped his age, and evinced so complete a superiority to its prejudices and superstitions. Bekker's work, indeed, had the misfortune to appear too soon; and of this he was early made sensible, by the torrent of abuse with which he was assailed, and the persecution he was called upon to undergo. What must have been the boldness and courage of that man who, in an age when the wildest fictions of demonology and witchcraft were implicitly, nay almost universally believed, commenced his attack on them by declaring, "C'est pour détruire cette vaine idole de la crédulité populaire que j'ai écrit mon livre: si le démon s'en fâche, qu'il emploie sa puissance pour m'en punir; s'il est Dieu, qu'il se défende lui-même, et qu'il s'en prenne à moi qui ait renversé ses autels!"

When Lucian ridiculed apparitions, and laughed at those who believed in them, he thought only of the lies, impostures, and absurdities which the ignorant and credulous had received as undoubted facts. All the passions exaggerate, and none more so than that of fear, the parent of superstition. Hence every thing seen through such a medium is beheld distorted, and out of all natural proportion. But, in cases of this description, it too frequently happens that the love of the marvellous comes in to finish the caricature which passion had commenced; and that imagination performs the double function of first imposing upon the seer himself, and afterwards contributing to enable him to impose still farther upon others. It is certain, indeed, that most if not all of the ghost stories which have been told are grossly exaggerated in almost every particular. Indeed, with the exception of Nicolai's truly philosophical narrative of the spectral illusions, which he beheld during a period of strong excitement produced by various misfortunes,[2] we scarcely know of a single case which does not bear on the face of it evident marks of embellishment and romance. Hence the difficulty of forming any theory of apparitions, to which, as matters stand, strong objections may not be taken, on the ground of its not embracing all, or even a majority, of the cases reported. We still want data upon which we can safely rely: and this want is to be ascribed mainly, if not solely, to the circumstance that every reporter was not a Nicolai; and that most of them have chosen rather to pander to the appetite for the marvellous than to tell their story simply and rationally. Lucian perceived this tendency of human nature, and unphilosophically ridiculed all apparitions as gross impositions on the credulity of the world; while the inquirers of the period to which we refer went to the opposite extreme, and, admitting every legend as authentic, racked their brains to account for what was in its own nature inexplicable upon any metaphysical theory. They never thought of cross-interrogating the witnesses before proceeding to consider the import of their testimony, or of endeavouring to test the credibility of the evidence before attempting to construct a theory out of it. They believed every thing without discrimination, and therefore could account for nothing. Thus Reginald Scot ridicules the paganism of the Church of Rome, yet comes to the conclusion that all her saints are as authentic devils as any in Pandemonium. Burton is scarcely more fortunate; and later inquirers, who finally gave up Satan and his invisible world altogether, landed in absurdities nearly as great as those they attempted to expose, though of course incomparably less mischievous.

But the progress of discovery and knowledge, independently of all theory, has cleared away many of the marvels which puzzled our ancestors. The devils, for example, which Benvenuto Cellini saw when he got into the conjurer's circle are now known to have been produced by a magic lantern; the Giant of the Broken, in the Hartz Mountains, has lost all his terrors since it was discovered that the spectre which had frightened men for ages is nothing more than the image of the individual who happens to be on the mountain-top at sun-rise reflected from the clouds beyond in gigantic proportions; and the Fata Morgana, as well as the Mirage, are now classed as pseudo-apparitions.

Of the more modern attempts to account for apparitions, the first which we shall notice is attributed to Meyer, and proceeds upon a particular theory respecting the origin of ideas, the conception of which appears to have

[1] One of the charges, it seems, against Dr Bekker, in the libel tried by the synod which ultimately deposed him, was his having attempted to banish all devils from the world. This absurd charge proceeded upon a complete misunderstanding of the whole gist and tenor of the work upon which it professes to be grounded. Dr Bekker does not deny the existence of the devil, as taught in Scripture, and is indeed most anxious to guard against such a construction being put upon his words, or such an inference deduced from his reasonings. The following passage, which is otherwise interesting, sets this in the clearest light:—"Ainsi la vérité de la Foy Chrétienne peut subsister, sans pourtant rien croire de la magie; ainsi moins l'on pense savoir ce que c'est que le diable, *à la reserve de ce que l'Ecriture nous en enseigne*, plus l'on peut connoître Dieu et Jesus Christ. Quand on ne connoit que Dieu, on en connoit assez; et toutes les connoissances qui sont hors de cet Etre Divin, ne sont que vanités et sottises." Scripture has declared that a knowledge of God is necessary to salvation; but it has nowhere said, so far as we remember, that, unless men know and believe in the devil, they will be damned. Dr Bekker, however, knew and believed all that the Scripture, rationally interpreted, warrants us to believe respecting the father of lies; and if his belief did not rise exactly to the pitch required by the demonologists of the Dutch synod, but, on the contrary, recoiled from their diabolical dogmas, it is precisely this inferiority of faith, conjoined with his manifest superiority of reason, which entitles him to the respect of all who can appreciate the honest boldness which enabled him to rise above the prejudices of his age, and to assail the abominations by which it was degraded and enslaved.

[2] Memoir on the Appearance of Spectres or Phantoms occasioned by Disease, with Psychological Remarks. Read by Nicolai to the Royal Society of Berlin on the 28th of February 1799. See a translation of this paper in *Nicolson's Journal*, vol. vi. p. 161. See also a good Memoir by Dr Alderson of Hull, in *Edinburgh Medical and Surgical Journal*, vol. vi.

been derived from the subtile images of Epicurus. These, the reader will remember, were held by the Epicureans to be spontaneously exhaled or given off by all bodies; and, when they entered the mind, or, we should rather say, were impressed on the attenuated atoms or corpuscles, of the material soul, were supposed to generate spectral illusions. Rejecting the notion of exhalation, however, M. Meyer adhered to the spirit of this philosophy; contending that all our ideas are material, and that they are transported from unknown sources to the storehouse of the memory, through the medium of the organs of sense. Hence it was conceived, that the nerves upon which sensations depend might not only be affected by external agents, but impressed by internal causes, and that the result of this impression would be hallucinations or illusions. Thus, rays of light impressing the optic nerves from without might cause the sensation of yellow, while corrupt humours, as those of jaundice for instance, by impressing the nerves from within, might produce a similar effect. Further, as ideas were held to be material, and might be treasured up by the memory, it was conceived that they might, through some unknown channel, find their way to the nerves, and impress them after the manner of internal causes influencing the mind. "I shall suppose," says M. Meyer, "that I have lost a parent whom I loved, and whom I have seen and spoken to an infinity of times. Having perceived him often, I have consequently preserved the material figure and perception of him in the brain; for it is very possible and reconcilable to appearances, that a material figure, like that of my deceased friend, may be preserved for a long time in my brain, even after his death. By some intimate yet unknown relation, therefore, which the figure may have to my body, it may touch the optic or acoustic nerves. In the very moment, then, that my nerves are affected in the same manner that they formerly were when I saw or listened to my living friend, I shall be necessarily induced to believe that I really see or hear him, as if he were present."[1] This has certainly the merit of being *teres atque rotundus;* but, in the first place, it proceeds upon the assumed materiality of ideas, which, besides being abandoned by all philosophers, is an assumption that is far from being self-evident, and can never be proved; secondly, M. Meyer is forced at every step to take for granted some new principle, in regard to the re-action of these material ideas on the nervous system, that equally requires, without admitting of, proof; lastly, he ascribes to his ideas the functions performed by the imagination, and thus infuses an ingredient of truth which gives a colour of plausibility to his theory.

Dr Ferriar's *Theory of Apparitions*, as he has been pleased to call his very entertaining collection of ghost stories, is a complete misnomer, inasmuch as the book really contains no theory at all. "It is a well-known law," says he at the outset, "that the impressions produced on some of the external senses, especially on the eye, are more durable than the application of the impressing cause." It certainly required no ghost to tell us this; yet it is all that Dr Ferriar has vouchsafed to give us of a theoretical kind; "and," as Dr Hibbert pertinently remarks, "the brevity with which it is given is in exact conformity with the abruptness of its dismissal; for, after being applied to explain one or two cases only of mental illusions, numerous other instances of the kind are related, but the theory is not honoured with any further notice." Still the book is valuable as a collection of cases establishing the existence of morbid impressions, without any sensible external agency, and also as showing the power which the imagination possesses under particular circumstances, of re-acting upon the organs of sense with an intensity sufficient to create a temporary belief in the reality of the objects, the impressions of which are thus renovated and vivified.[2]

The work of Dr Hibbert, modestly entitled *Sketches of the Philosophy of Apparitions,* is of a different description from that of Dr Ferriar. In it a theory is distinctly propounded, and followed up through a vast complexity of details, which the theory is employed to explain and reconcile; and if the author had carried his generalization a step further, and at the same time paid more attention to the logical arrangement of his topics, he would have left little to be supplied by any future writer on this curious branch of the philosophy of the human mind. As it is, however, the book is full of interesting matter, and, what is of still greater importance, it furnishes ample materials for extending and enlarging the view of the subject, which the author has, upon the whole, so satisfactorily developed. After a not very skilful sketch of the opinions, ancient and modern, which have been entertained respecting apparitions, Dr Hibbert proceeds, in the *first* place, to consider the morbid affections with which the production of phantasms is often connected; *2dly,* to show that the objects of spectral illusions are frequently suggested by the fantastic imagery of superstitious belief; *3dly,* to investigate the mental laws which give rise to spectral illusions; *4thly,* to notice the modifications which the intellectual faculty often undergoes during intense excitements of the mind; and, *lastly,* to state the comparative degrees of faintness, vividness, or intensity subsisting between sensations and ideas during their various excitements and depressions. And the general result at which he arrives, or, in other words, the law which connects and explains all the phenomena of apparitions, whether arising from morbid affections suggested by the fantastic imagery of superstition, or induced by certain states of the mind without any sensible extrinsic agency, is this, viz. "That apparitions are no-

[1] *Essay on Apparitions,* attributed to M. Meyer, professor in the university of Halle, 1748.

[2] An anecdote is told by this author, which serves to illustrate the incidental observation in the text:—"A gentleman was benighted, while travelling alone, in a remote part of the Highlands of Scotland, and was compelled to ask shelter for the evening at a small lonely hut. When he was to be conducted to his bed-room, the landlady observed, with mysterious reluctance, that he would find the window very secure. On examination, part of the wall appeared to have been broken down to enlarge the opening. After some inquiry, he was told that a pedlar, who had lodged in the same room a short time before, had committed suicide, and was found hanging behind the door in the morning. According to the superstition of the country, it was deemed improper to remove the body through the door of the house; and to convey it through the window was impossible, without removing part of the wall. Some hints were dropped that the room had been subsequently haunted by the poor man's spirit. My friend laid his arms, properly prepared against intrusion of any kind, by the bed-side, and retired to rest, not without some degree of apprehension. He was visited in a dream by a frightful apparition, and, awaking in agony, found himself sitting up in bed, with a pistol grasped in his right hand. On casting a fearful glance round the room, he discovered, by the moonlight, a corpse dressed in a shroud, reared erect against the wall, close to the window. With much difficulty he summoned up resolution to approach the dismal object, the features of which, and the minutest parts of its funeral apparel, he perceived distinctly. He passed one hand over it, felt nothing, and staggered back to the bed. After a long interval, and much reasoning with himself, he renewed his investigation, and at length discovered that *the object of his terror was produced by the moon-beams forming a long bright image through the broken window,* on which his fancy, *impressed by his dream,* had pictured, with mischievous accuracy, the lineaments of a body prepared for interment. Powerful associations of terror, in this instance, had excited the recollected images with uncommon force and effect

thing more than ideas, or the recollected images of the mind, which have been rendered as vivid as actual impressions;" a principle which, though somewhat incuriously expressed, makes, in our opinion, a very close approximation to the truth.

Dr Hibbert further conceives that the organs of sense are the actual medium through which past feelings are renovated; or, in other words, that when, from strong mental excitement, ideas have become as vivid as past impressions, or even more so, this intensity is induced by, or rather productive of, an absolute affection of those particular parts of the organic structure on which sensations depend; in the same way precisely as the salivary glands are known to be occasionally as much excited by the idea of some favourite food, as if the sapid body itself were actually present, stimulating the *papillæ* of the *fauces*. It would have been more simple and equally true if Dr Hibbert had said that the imagination, in some states, re-acts upon the organs of sense, and renovates past feelings or sensations, the natural antecedents of certain perceptions, with an intensity sufficient to create an illusion of reality; and this statement would have had the double advantage, of not only expressing, in a more generalized form, the important law of the human mind, which it is the object of all Dr Hibbert's investigations to evolve, but at the same time of excluding the particular views of physiology which are more or less mixed up with his metaphysical speculations. But the re-action in question may be either of a pleasurable kind or the reverse, according to the nature of the causes by which it is primarily produced; and as the mind can only exist in one state at an indivisible instant of time, it follows that when any agent, morbific or other, adds to the general vividness of our pleasurable feelings, those of an opposite or painful kind become proportionally less vivid, or rather are for the moment excluded; and, *vice versa*, the same law holds in regard to all our painful feelings, the increased intensity of which is necessarily accompanied with a corresponding abatement of those of an opposite kind. As the mind, however, passes from one state to another, or alternates between opposite states, with inconceivable rapidity, memory is sometimes apt to blend the recollected feelings of the one with those of the other, and thus to create a confusion in our conceptions of things which are in their own nature perfectly distinct. In some cases, where the nitrous oxide was administered, the patient, while under its influence, vibrated between perfect happiness and most consummate misery; but in the majority of instances the sensations produced were of a pleasurable description, to the exclusion of all those of an opposite kind; just as the sensations produced by an attack of the febrile miasma are almost invariably and exclusively those of the most acute pain. Hence the law above stated may be considered as a general one, when taken with the modifications proper to be applied to it. Lastly, Dr Hibbert has shown, that when mental feelings of any description attain a certain degree of vividness or intensity, muscular motions obey the impulse of the will, which is as much influenced by the re-acting and renovating power of imagination, as by any of our ordinary passions, appetites, or desires.

These principles, if we are not mistaken, go far to explain all the phenomena of dreams and apparitions; for the latter are merely waking dreams, and differ from the former in degree only, not in kind. In the case of Nicolai, which, as Dr Ferriar justly remarks, is one of the extreme instances of mental delusion which a man of strong judgment has ventured to report of himself, past impressions were renovated with the utmost accuracy and minuteness. The philosophical seer of Berlin beheld no "gorgons, hydras, and chimæras dire." The visions which he saw were neither terrible, ludicrous, nor repulsive; on the contrary, most of them were ordinary in their appearance, and some of them even agreeable. They were generally phantasms of his friends and acquaintance; or, in other words, exact copies of his past impressions and perceptions, so renovated and vivified as to create an illusion of reality, though for the most part oddly, if not grotesquely, put together. The story told so well by Dr Ferriar of the vision seen by the benighted gentleman who took up his quarters in the lonely Highland hut, is explicable on precisely the same principle; for his imagination, excited by his dream, pictured the corpse of the self-murdered pedlar behind the door by renovating and vivifying the mental images produced by the recital of the circumstances previously given to the traveller. In the cases of disease or superstition, again, the exciting causes are different, and the illusions generated consequently vary; but, in every instance where we can get at the circumstances, it will be found that these illusions or phantasms are merely vivid renovations of mental impressions previously received, and that, although the grouping may be fantastical, the ordinary laws of association are never transgressed.

Dr Brewster has remarked, as a physical fact, that "when the eye is not exposed to the impressions of external objects, or when it is insensible to these objects in consequence of being engrossed with its own operations, any object of mental contemplation, which has either been called up by the memory or created by the imagination, *will be seen as distinctly as if it had been formed from the vision of a real object.* In examining these mental impressions," he adds, "I have found that they follow the motions of the eye-ball exactly like the spectral impressions of luminous objects, and that they resemble them also in their apparent immobility when the eye-ball is displaced by an external force. If this result shall be found generally true by others, it will follow that the objects of mental contemplation *may be seen as distinctly as external objects*, and will occupy *the same local position in the axis of vision* as if they had been formed by the agency of light."[1] This goes to the very root of the theory of apparitions; all the phenomena of which seem to depend upon the relative intensities of the two classes of impressions, and upon the manner of their accidental combination. In perfect health, the mind not only possesses a control over its powers, but the impressions of external objects alone occupy its attention, and the play of imagination is consequently checked, except in sleep, when its operations are relatively more feeble and faint. But in the unhealthy state of the mind, when its attention is partly withdrawn from the contemplation of external objects, the impressions of its own creation, or rather reproduction, will either overpower or combine themselves with the impressions of external objects, and thus generate illusions which in the one case appear alone, while in the other they are seen projected among those external objects to which the eye-ball is directed, in the manner explained by Dr Brewster. We may add, that the same reasoning which applies to the impressions derived from the sense of sight, is equally applicable to those received

[1] See in the *Edinburgh Journal of Science*, conducted by Dr Brewster, a paper by the editor, entitled "Observations on the Vision of Impressions on the Retina, in reference to certain supposed Discoveries respecting Visions announced by Mr Charles Bell." Vol. ii. p. 1.

through the medium of any other sense,—as the ear, for instance, an organ which ministers abundantly to the production of spectral illusions.

Again, with regard to those illusions, the objects of which are, according to this theory, suggested by the imagery of superstition, it is obvious that a belief in such imagery is calculated, in an ignorant and credulous age, to make a strong impression on the mind, and to imbue it deeply with all the peculiarities of the prevailing creed. In point of fact, there is nothing which men know so thoroughly, or remember so minutely, as superstitious legends, when this unearthly lore forms the subject of unquestioned and unquestionable belief. But all such impressions are more or less productive of and accompanied with fear; and hence when, from accidental circumstances, this passion happens to be excited to any degree of intensity, it not only withdraws the attention of the mind from the contemplation of external objects, but at the same time stimulates the imagination; which, again, reacts through the senses, vivifying mental images alone, or perhaps intermingling them, in fantastical combinations, with the impressions derived from external objects, and thus creating those spectral illusions which dreamers and seers in all ages have mistaken for realities. If the force of imagination alone can in some instances, without any sensible extrinsic agency, generate unreal mockeries and phantasms, much more must it do so when excited by a belief in supernatural agency, reinforced by fear, the most powerful of all the passions. "What brighter colours the fears of superstition give to the dim objects perceived in twilight, the inhabitants of the village," says Dr Thomas Brown, "who have to pass the churchyard at any late hour, and the little students of ballad-lore, who have carried with them, from the nursery, many tales which they almost tremble to remember, know well. And in the second sight[1] of this northern part of the island, there can be no doubt, that the objects which the seers conceive themselves to behold, are truly more vivid as conceptions, than, but for the superstitious and melancholy character of the natives, which harmonize with the objects of this foresight, they would have been; and that it is in consequence of this brightening effect of the emotion, as concurring with the dim and shadowy objects which the vapoury atmosphere of our lakes and valleys presents, that *fancy, relatively to the individual, becomes a temporary reality*. The gifted eye, which has once believed itself favoured with such a view of the future, will, of course, ever after have a quicker foresight, and more frequent revelations; its own wilder emotion communicating still more vivid forms and colours to the objects which it dimly perceives." In the case of such visions, however, there is often more of delusion in the seer, than of illusion in the phantasms which his "gifted eye" is supposed to have beheld; and hence the difficulty, as we have already remarked, or perhaps it would be more correct to say the impossibility, of explaining upon any one theory all the phenomena, as these have been detailed. But although it is inconsistent with the object of this article to diverge into illustrations in detail, we may be permitted to observe that all the narratives of spectral illusions which can be relied upon as deserving of credit, are perfectly explicable upon the principles here briefly but we trust intelligibly unfolded.

Having said thus much in reference to the theory of apparitions, it will not be necessary to enter at any length into that part of Sir Walter Scott's work on demonology and witchcraft[2] which relates to the present subject. Sir Walter has indeed attempted to sound the very depths of the philosophy of spectral illusion, and to account for their phenomena on known or admitted principles; but, with all possible respect and deference for this gifted writer, it may be doubted whether his line has reached the bottom, or afforded any just measure of its profundity. He has narrated, with a skill and effect peculiar to himself, a number of very striking cases,[3] and has connected these by a variety of observations, some of them not less remarkable for the

---

[1] Most of the stories of second-sight told by the Highlanders seem arrant fabrications; and although we are by no means inclined to doubt the possibility of such illusions, any more than to question the fact, that they have sometimes accidentally coincided in point of time with events which seemed to give some confirmation to the belief in deuteroscopy, yet there is so much absurdity and imposture in nearly all the narratives of this kind which we have read, that we consider them utterly unworthy of serious consideration. The honest fellow who proposed to sell the secret for a pound of tobacco, knew more of the mysteries of second-sight than some grave philosophers. Dr John Macculloch has the following very pertinent remarks on the subject:—"To have circumnavigated the Western Isles without even mentioning the second-sight, would be unpardonable. No inhabitant of St Kilda pretends to have been forewarned of our arrival; ceasing to be believed, it has ceased to exist. It is indifferent whether the propagators of an imposture, or of a piece of supernatural philosophy, be punished or rewarded. In either case the public attention is directed towards the agent; whether by the burning of the witch, or by the flattering distinction which attended the Highland seer. When witches were no longer burned, witchcraft disappeared. Since the second-sight has been limited to a doting old man, or a hypochondriacal tailor, it has been a subject for ridicule; and in matters of this nature ridicule is death." (*Description of the Western Isles*, by John Macculloch, M. D. vol. ii. p. 32.) While the world believed in the second-sight and in witchcraft, there never failed to be seers and witches. The supposed possession of these faculties insured notoriety, flattered vanity, conferred power, and afforded the means of gratifying malice: And what will not men and women do to attain distinctions and advantages like these? The vain will covet them, the ambitious will grasp at them, the malicious, if otherwise helpless and spited at the world, will run all risks, both here and hereafter, to secure them. Hence the enormous impostures of witchcraft, and hence also delusions as hideous as the knavery was gross and revolting. This is the true key to the solution of a vast number of cases which, it has been supposed, we can neither believe, account for, nor refute. But the misfortune is, that most of those who have written on the subject have had more faith than philosophy, and more fancy than faith, in consequence of which they have jumbled truth and falsehood together in such wild confusion, that all the alchemy of logic is insufficient to resolve the compound into its constituent elements, and separate the one from the other.

[2] *Letters on Demonology and Witchcraft*, addressed to J. G. Lockhart, Esq. By Sir Walter Scott, Bart.

[3] The following is one of the *most* striking, and although the narrative be long, it will be found exceedingly interesting:—"A second, and equally remarkable instance, was communicated to the author by the medical man under whose observation it fell, but who was, of course, desirous to keep private the name of the hero of so singular a history. Of the friend by whom the facts were attested, I can only say, that if I found myself at liberty to name him, the rank which he holds in his profession, as well as his attainments in science and philosophy, form an undisputed claim to the most implicit credit.

"It was the fortune of this gentleman to be called in to attend the illness of a person now long deceased, who in his lifetime stood, as I understand, high in a particular department of the law, which often placed the property of others at his discretion and control, and whose conduct, therefore, being open to public observation, he had for many years borne the character of a man of unusual steadiness, good sense, and integrity. He was, at the time of my friend's visits, confined principally to his sick-room, sometimes to bed, yet occasionally attending to business, and exerting his mind, apparently with all its usual strength and energy, to the conduct of important affairs intrusted to him; nor did there, to a superficial observer, appear any thing in his conduct, while so engaged, that could argue vacillation of intellect or depression of mind. His outward symptoms of malady argued no acute or alarming disease. But slowness of pulse, absence of appetite, difficulty of digestion, and constant depression of spirits, seemed to draw their origin from

 acuteness they display, than for the very great felicity with which they are expressed. But even with Dr Hibbert's work as a guide, and all the collateral lights which have been thrown upon the subject by the researches of

some hidden cause, which the patient was determined to conceal. The deep gloom of the unfortunate gentleman—the embarrassment, which he could not conceal from his friendly physician—the briefness and obvious constraint with which he answered the interrogations of his medical adviser—induced my friend to take other methods for prosecuting his enquiries. He applied to the sufferer's family, to learn, if possible, the source of that secret grief which was gnawing the heart and sucking the life-blood of his unfortunate patient. The persons applied to, after conversing together previously, denied all knowledge of any cause for the burden which obviously affected their relative. So far as they knew—and they thought they could hardly be deceived—his worldly affairs were prosperous; no family loss had occurred which could be followed with such persevering distress; no entanglements of affection could be supposed to apply to his age, and no sensation of severe remorse could be consistent with his character. The medical gentleman had finally recourse to serious argument with the invalid himself, and urged to him the folly of devoting himself to a lingering and melancholy death, rather than tell the subject of affliction which was thus wasting him. He specially pressed upon him the injury which he was doing to his own character, by suffering it to be inferred that the secret cause of his dejection, and its consequences, was something too scandalous or flagitious to be made known, bequeathing in this manner to his family a suspected and dishonoured name, and leaving a memory with which might be associated the idea of guilt, which the criminal had died without confessing. The patient, more moved by this species of appeal than by any which had yet been urged, expressed his desire to speak out frankly to Dr ——. Every one else was removed, and the door of the sick-room made secure, when he began his confession in the following manner:—

"'You cannot, my dear friend, be more conscious than I, that I am in the course of dying under the oppression of the fatal disease which consumes my vital powers; but neither can you understand the nature of my complaint, and the manner in which it acts upon me; nor, if you did, I fear, could your zeal and skill avail to rid me of it.'—'It is possible,' said the physician, 'that my skill may not equal my wish of serving you; yet medical science has many resources, of which those unacquainted with its powers never can form an estimate. But until you plainly tell me your symptoms of complaint, it is impossible for either of us to say what may or may not be in my power, or within that of medicine.'—'I may answer you,' replied the patient, 'that my case is not a singular one, since we read of it in the famous novel of Le Sage. You remember, doubtless, the disease of which the Duke d'Olivarez is there stated to have died?'—'Of the idea,' answered the medical gentleman, 'that he was haunted by an apparition, to the actual existence of which he gave no credit, but died, nevertheless, because he was overcome and heart-broken by its imaginary presence.'—'I, my dearest Doctor,' said the sick man, 'am in that very case; and so painful and abhorrent is the presence of the persecuting vision, that my reason is totally inadequate to combat the effects of my morbid imagination, and I am sensible I am dying, a wasted victim to an imaginary disease.' The medical gentleman listened with anxiety to his patient's statement, and for the present judiciously avoiding any contradiction of the sick man's preconceived fancy, contented himself with more minute enquiry into the nature of the apparition with which he conceived himself haunted, and into the history of the mode by which so singular a disease had made itself master of his imagination, secured, as it seemed, by strong powers of the understanding, against an attack so irregular. The sick person replied by stating, that its advances were gradual, and at first not of a terrible or even disagreeable character. To illustrate this, he gave the following account of the progress of his disease.

"'My visions,' he said, 'commenced two or three years since, when I found myself from time to time embarrassed by the presence of a large cat, which came and disappeared I could not exactly tell how, till the truth was finally forced upon me, and I was compelled to regard it as no domestic household cat, but as a bubble of the elements, which had no existence save in my deranged visual organs or depraved imagination. Still I had not that positive objection to the animal entertained by a late gallant Highland chieftain, who has been seen to change to all the colours of his own plaid if a cat by accident happened to be in the room with him, even though he did not see it. On the contrary, I am rather a friend to cats, and endured with so much equanimity the presence of my imaginary attendant, that it had become almost indifferent to me; when within the course of a few months it gave place to, or was succeeded by, a spectre of a more important sort, or which at least had a more imposing appearance. This was no other than the apparition of a gentleman-usher, dressed as if to wait upon a lord-lieutenant of Ireland, a lord high commissioner of the kirk, or any other who bears on his brow the rank and stamp of delegated sovereignty.

"'This personage, arrayed in a court dress, with bag and sword, tamboured waistcoat, and *chapeau-bras*, glided beside me like the ghost of Beau Nash; and, whether in my own house or in another, ascended the stairs before me, as if to announce me in the drawing-room; and at some times appeared to mingle with the company, though it was sufficiently evident that they were not aware of his presence, and that I alone was sensible of the visionary honours which this imaginary being seemed desirous to render me. This freak of the fancy did not produce much impression on me, though it led me to entertain doubts on the nature of my disorder, and alarm for the effect it might produce upon my intellects. But that modification of my disease also had its appointed duration. After a few months the phantom of the gentleman-usher was seen no more, but was succeeded by one horrible to the sight and distressing to the imagination, being no other than the image of death itself—the apparition of a *skeleton*. Alone or in company,' said the unfortunate invalid, 'the presence of this last phantom never quits me. I in vain tell myself a hundred times over that it is no reality, but merely an image summoned up by the morbid acuteness of my own excited imagination and deranged organs of sight. But what avail such reflections, while the emblem at once and presage of mortality is before my eyes, and while I feel myself, though in fancy only, the companion of a phantom representing a ghastly inhabitant of the grave, even while I yet breathe on the earth? Science, philosophy, even religion, has no cure for such a disorder; and I feel too surely that I shall die the victim to so melancholy a disease, although I have no belief whatever in the reality of the phantom which it places before me.'

"The physician was distressed to perceive, from these details, how strongly this visionary apparition was fixed in the imagination of his patient. He ingeniously urged the sick man, who was then in bed, with questions concerning the circumstances of the phantom's appearance, trusting he might lead him, as a sensible man, into such contradictions and inconsistencies as might bring his common sense, which seemed to be unimpaired, so strongly into the field, as might combat successfully the fantastic disorder which produced such fatal effects. 'This skeleton, then,' said the Doctor, 'seems to you to be always present to your eyes?'—'It is my fate, unhappily,' answered the invalid, 'always to see it.'—'Then I understand,' continued the physician, 'it is now present to your imagination?'—'To my imagination it certainly is so,' replied the sick man.—'And in what part of the chamber do you now conceive the apparition to appear?' the physician enquired. 'Immediately at the foot of my bed; when the curtains are left a little open,' answered the invalid, 'the skeleton, to my thinking, is placed between them, and fills the vacant space.'—'You say you are sensible of the delusion,' said his friend; 'have you firmness to convince yourself of the truth of this? Can you take courage enough to rise and place yourself in the spot so seeming to be occupied, and convince yourself of the illusion?' The poor man sighed, and shook his head negatively. 'Well,' said the Doctor, 'we will try the experiment otherwise.' Accordingly, he rose from his chair by the bedside, and placing himself between the two half-drawn curtains at the foot of the bed, indicated as the place occupied by the apparition, asked if the spectre was still visible? 'Not entirely so,' replied the patient, 'because your person is betwixt him and me; but I observe his skull peering above your shoulder.'

"It is alleged the man of science started on the instant, despite philosophy, on receiving an answer ascertaining, with such minuteness, that the ideal spectre was close to his own person. He resorted to other means of investigation and cure, but with equally indifferent success. The patient sunk into deeper and deeper dejection, and died in the same distress of mind in which he had spent the latter months of his life; and his case remains a melancholy instance of the power of imagination to kill the body, even when its fantastic terrors cannot overcome the intellect, of the unfortunate persons who suffer under them. The patient, in the present case, sunk under his malady; and the circumstances of his singular disorder remaining concealed, he did not, by his death and last illness, lose any of the well-merited reputation for prudence and sagacity which had attended him during the whole course of his life."

Dr Ferriar, Sir David Brewster, &c., Sir Walter has failed to reach any general principle applicable to a given class of cases. The consequence is, that, although his observations are almost always valuable, and often involve the very law which connects and explains the phenomena of spectral illusion, he constantly stops short on the verge of the discovery, and is therefore under the necessity of seeking a new explanation of each successive case, which is, for the most part, considered separately and without reference to or comparison with others. On several occasions, indeed, he attempts to generalize, and makes very close approximations to the truth; but, like those tuneless persons who sometimes essay good-naturedly to sing, and stumble about the outskirts of an air, without ever being able to hit it exactly, Sir Walter frequently comes so very near the point he aims at, that we are surprised how he should miss it.

This is singularly exemplified in the following observations, which, with reference to the view we have now taken, are exceedingly important:—"Enthusiastic feelings of an impressive and solemn nature," says Sir Walter, "occur both in private and public life, which seem to add ocular testimony to an intercourse betwixt earth and the world beyond it. For example, the son who has been lately deprived of his father feels a sudden crisis approach, in which he is anxious to have recourse to his sagacious advice—or a bereaved husband earnestly desires again to behold the form of which the grave has deprived him for ever—or, to use a darker yet very common instance, the wretched man who has dipped his hand in his fellow-creature's blood, is haunted by the apprehension that the phantom of the slain stands by the bedside of his murderer. In all, or any of these cases, who shall doubt that *imagination*, favoured by circumstances, *has power to summon up to the organ of sight spectres which only exist in the mind of those by whom their apparition seems to be witnessed?* If we add, that such a vision may take place in the course of one of those lively dreams in which the patient, except in respect to the single subject of *one* strong impression, is or seems sensible of the real particulars of the scene around him, a state of slumber which often occurs—if he is so far conscious, for example, as to know that he is lying on his own bed, and surrounded by his own familiar furniture, at the time when the supposed apparition is manifested, it becomes almost in vain to argue with the visionary against the reality of his dream, since the spectre, though itself purely fanciful, *is inserted* amidst so many circumstances which he feels must be true beyond the reach of doubt or question. That which is undeniably certain becomes in a manner a warrant for the reality of the appearance to which doubt would have been otherwise attached. And if any event, such as the death of the person dreamt of, *chances to take place*, so as to correspond with the nature and the time of the apparition, *the coincidence*, though one which must be frequent, since our dreams usually refer to the accomplishment of that which haunts our minds when awake, and often presage the most probable events, seems perfect, and the chain of circumstances touching the evidence may not unreasonably be considered as complete."

Now, it must be obvious to every one, that the true theory of apparitions is involved in these observations, though not unfolded in such a manner as to render it available for the explanation of spectral illusions. The author distinctly indicates, in the first place, the power of imagination, when excited, "to summon up to the organ of sight spectres which only exist in the mind of those by whom their apparition seems to be witnessed," or, in other words, to reproduce past impressions through the medium of the senses; and, secondly, in certain kinds of *dreams*, he recognises the principle, which Sir D. Brewster has shown to hold good in our waking hours, that "the objects of mental contemplation may be seen as distinctly as external objects, and will occupy the same local position in the axis of vision, as if they had been formed by the agency of light;" while their being "inserted" amidst so many objects in regard to which there is no deception, will at the same time contribute to strengthen the illusion of reality, and to render the visionary inaccessible to any arguments tending to call it in question. But no use whatever is made of these important principles; which, so far from being pushed to their consequences, and thus disencumbered of the limitations which the author has assigned to them, are stated apparently for no other reason than that they may be straightway cast aside and forgotten.

Another example may be given of this unavailing approximation to the truth, on a most important branch of the subject. That disordered or excited state of the imagination arising from morbific causes, in which it re-acts upon the organs of sense, and generates spectral illusions, "is not," he thinks, "properly insanity, although it is somewhat allied to that most horrible of maladies, and may, in many constitutions, be the means of bringing it on, and although such hallucinations are proper to both." The difference he conceives to be, that "in cases of insanity, the mind of the patient is principally affected, while the senses or organic system offer in vain to the lunatic their decided testimony against the phantasy of a diseased imagination." There is some confusion here, both in conception and expression; but still the author is correct in his general idea, however vaguely indicated, that the difference he alludes to is one of degree rather than of kind. A few observations will, we think, make this abundantly evident, and at the same time show in how remarkable a manner the phenomena of insanity, viewed in reference to the subject before us, illustrate that reflective or renovating power of the imagination to which alone we ascribe the production of phantasms and spectres.

The history of this malady (says Pinel) claims alliance with all the errors and delusions of superstitious credulity —with those of witchcraft, demoniacal possession, oracles, divinations, and spectral illusions; and hence he considers it as eminently deserving of attention, on the part of the mental, as well as on that of the medical philosopher who may be called upon practically to minister consolation and relief to minds diseased. Insanity, considered generally, is merely the excess of that state or of those states of the mind during which hallucinations are produced; and this excess, when prolonged beyond a certain limit, terminates in fatuity, or the complete exhaustion and paralysis of the mental powers, just as bodily exertion, when urged beyond a certain pitch (varying, however, in each individual), terminates in the suspension of all physical energy, and ultimately in death. In both cases nature has provided a restorative power, which, up to a definitive point, can repair the injury produced by excited action, and enable the mind and body to recover their wonted tone and health; but if the excitation continue, or be pushed beyond this limit, the restorative efficacy is destroyed, and neither can ever regain their former condition. It is this excess alone which, in the case of mind, constitutes insanity. It is the unnatural continuance or prolongation of excited action which ultimately overwhelms the whole mental powers; not even excepting the imagination itself, the very instrument, if we may so express it, by which this melancholy ruin is accomplished. Hence it is commonly observed that persons endowed with the greatest susceptibility of mental excitement, with the warmest passions, the most active imaginations, and the most acute sensibilities, evince the strongest pre-

Apparitions. disposition to insanity; and as this is the temperament that usually accompanies genius, every one can easily appreciate the truth of the observation which a celebrated poet has consecrated in his numbers, that great wit is nearly allied to madness, and that "thin partitions do the bounds divide" which separate the one from the other. But this predisposing temperament, of which genius is a natural product, and insanity the excess or diseased state, is also that which renders men peculiarly susceptible of superstitious impressions, and upon which these, when once received into the mind, and treasured up in the memory, are likely, through the medium of the imagination, to re-act with the greatest force, and thus to give a sort of reflex impulse to the temperament which predisposes towards their reception. Need we wonder, then, to find the imagery of superstition so frequently blended and mixed up with the wild delusions of insanity, or the one acting upon and aggravating all the symptoms of the other? Need we wonder that in a great variety of instances superstition should become the exciting cause of insanity, or that the visions of insanity should, in their turn, form new objects of superstition?

In all cases of mental excitement, howsoever produced, the results may vary in proportion to the relative intensity of the excited action; but on a close examination it will be found that the difference observable amongst them is a difference of degree only, not of kind. "From recalling images by an act of the memory," says Dr Ferriar, "the transition is direct to beholding spectral objects which have been floating in the imagination;" and he adds that he has frequently, in the course of his professional practice, conversed with persons who imagined they saw demons, and heard them speak; a species of delusion which, he thinks, admits of many gradations and distinctions exclusive of actual insanity. Sir Walter Scott also mentions the case of a patient similarly affected, who, being troubled with a diurnal vision of an unsightly hag, consulted the late Dr Gregory on the subject of this visitation, but, as appears from the narrative, without deriving any material benefit from the skill of that eminent and learned physician. As the spectre was very regular in its appearance, and always visited the patient at a stated hour, the doctor, on one occasion, exerted all his powers of conversation, which were very great, to engage the mind of this individual, and if possible beguile him into a forgetfulness of time, that the awful hour might pass unobserved—but, as it turned out, without effect; for scarcely had the clock struck the hour, when the patient screamed out that he beheld the apparition. Ordinary impressions, indeed, are never sufficient to control such as are produced by an imagination excited as this man's must have been. Hence, finding his expedient vain, Dr Gregory had recourse to his usual remedy of blood-letting, in order to relieve the plethoric or apoplectic affection under which he concluded that the patient must be labouring; but whether this antiphlogistic treatment had the effect of dismissing the phantom hag who had previously repeated her visits so regularly, Sir Walter has not informed us. Delusions of this sort, as Dr Ferriar observes, certainly admit of gradations short of actual insanity; but the difference, as we have already remarked, is one of degree only, not of kind; for, in all such cases, a little additional intensity of excitement is only wanting to deprive the mind of that power over its impressions generally which it has already lost over one set, and thus to overwhelm it at once under a hideous mass of morbid hallucinations. The same observation is applicable to the partial illusions generated by hysteria, hypochondria, febrile affections, inflammations of the brain, *delirium tremens*, and other diseases which exert a disturbing influence over the nervous system, especially that part of it more immediately connected with sensation. The exciting causes may vary, and the particular illusions created may partake of this variation; yet it will be found that, the excitement once produced, the resulting phenomena observe invariably the same law, and that according as the degree of that excitement is greater or less, so will the morbid affection of the mind either amount to actual insanity, or fall short of it by some gradations. The true theory of apparitions, therefore, is essentially the same with that of insanity; nor, in determining the general principle which connects the one class of phenomena, can we fail, if we pursue the proper course of investigation, to ascertain that which regulates and consequently explains the other.[1]

These observations, as the reader must have already perceived, apply only to that part of Sir Walter Scott's work which relates to apparitions, and which, in fact, is greatly inferior in interest as well as importance to the masterly exposition he has given of the various systems of magic and demonology which have prevailed at different times and in different countries. Here he is evidently quite at home; and as his treasures of ghostly lore are unbounded, his judicious observations are continually illustrated by the most apposite and striking narratives, frequently derived from sources which are not generally accessible. His remarks on the denunciation against witches contained in the Old Testament, as well as on the particular case of the sorceress of Endor, consulted by Saul, are exceedingly interesting; and we think the distinction he has drawn between Jewish witchcraft, which was connected with the abominations of idolatry, and that of modern times, which was the joint product of ignorance, credulity, fear, persecution, and imposture, perfectly sound. That the witch of Endor was a mere fortune-teller, to whom the unfortunate king of Israel had recourse in his despair, is beyond all question or doubt; and the only difficulty is to explain how it was so ordained that the spirit of the prophet Samuel should arise amidst the incantations of an impostor, and thus lend a

[1] The activity which the soul frequently displays during sleep, or, in other words, the phenomena of dreams, engaged the attention of metaphysicians at an early period, and gave rise to numerous learned and ingenious speculations, an exquisite summary of which, accompanied with many truly refined and subtile observations of his own, the reader will find in the chapter where Mr Dugald Stewart treats of this subject in his *Elements of the Philosophy of the Human Mind.* "Dreams," says Mr Addison, "look like the relaxations and amusements of the soul when she is disencumbered of her machine; her sports and recreations when she has laid her charge asleep. The soul is clogged and retarded in her operations when she acts in conjunction with a companion that is so heavy and unwieldy in its motions; but in dreams she converses with numberless beings of her own creation, and is transported into ten thousand scenes of her own raising. She is herself the theatre, the actor, and the beholder." This is finely said, and not more beautiful than true. But the reader will not fail to observe, that as Mr Addison's description, if somewhat heightened in its colouring and distorted in its features, would apply to insanity as well as to dreams, so the state of the soul which produces the one would, if highly excited, exhibit all the characteristic phenomena of the other. Dreams, indeed, are but faint adumbrations of that vivid phantasmagoria which madness presents to the eye of the mind, and which is also accompanied with an increased intensity in all the feelings and emotions of the soul, whether connected with the predominant hallucination, or otherwise. Hence Pinel has remarked, that, even during the intervals of comparative calmness and reason, he has nowhere met, except in romance, with fonder husbands, more affectionate parents, more impassioned lovers, or purer and more exalted patriots, than in an asylum for lunatics.

sort of countenance to the belief in magical charms and divinations, which was already but too generally and deeply rooted in the minds of the Israelites. This, however, is not the place to enter into the discussion of matters which properly fall to be treated of under different heads, and which involve principles totally different from those which are applicable to the case of apparitions alone. (J. B—E.)

APPARITOR, among the *Romans*, a general term to comprehend all attendants of judges and magistrates appointed to receive and execute their orders. *Apparitor*, in England, is a messenger that serves the process of a spiritual court, or a beadle in a university who carries the mace.

APPEAL, in its usual modern sense, is the act by which a decision is brought for review from an inferior to a superior court. In Roman jurisprudence it was used in this and in other significations; it was sometimes equivalent to prosecution, or the calling up of an accused person before a tribunal, where the accuser appealed to the protection of the magistrate against injustice or oppression. The derivation from the word *appello*, naturally shows its earliest meaning to have been an urgent outcry or prayer against injustice. Hence it inferred a superior power capable of protecting against petty tyranny. In its meaning of seeking a higher tribunal for recourse against a lower, it does not seem to have been a characteristic of the Republic, where the magistrate was generally supreme within his sphere, and those who felt themselves outraged by injustice, threw themselves on popular protection by *provocatio*, instead of looking to redress from a higher official authority. The Empire, however, introduced grades of jurisdiction, and the ultimate remedy was an appeal to the emperor; thus Paul, when brought before Festus, appealed unto Cæsar. It must be understood that the appeal was actually dealt with by a supreme judge representing the emperor, not by the emperor in person. In the *corpus juris*, the appeal to the emperor is called indiscriminately *appellatio* and *provocatio*. A considerable portion of the 49th book of the Pandects is devoted to appeals, but little of the practical operation of the system is to be derived from the propositions there brought together.

The ecclesiastical hierarchy, and the gradations of the feudal system, naturally afforded scope in the middle ages for appeals from the lower to the higher authority. In matters ecclesiastical, including those matrimonial testamentary and other departments which the church ever tried to bring within the operation of the canon law, there were various grades of appeal, ending with the Pope. The European princes in general struggled against this assumption of authority by the court of Rome, and it was the source of many contests between the ecclesiastical and the regal power.

It became customary for ambitious sovereigns to encourage appeals from the courts of the crown vassals, to themselves as represented by the supreme judges, and Charlemagne usually enjoys the credit of having set the example of this system of centralization, by establishing *missi dominici*. The great vassals, however, sought recourse against the decisions of the royal courts in their own order embodied as the great council or parliament of the nation, and hence arose the appeal to the House of Lords as the court of last resort.

When the progress of civilization and the art of self-government renders judges no longer amenable to the charge of tyranny or fraud, an appellate system changes its character and objects. It in some measure certainly tends to preserve that judicial integrity which renders it unnecessary as the immediate refuge of the persecuted suitor. But its ostensible object is the preservation of uniformity in the law. The attainment of this object renders it unfortunately necessary in such a country as ours, that no tribunal shall give, in the first instance, in any important question, a decision which is not open to appeal. The process has the double advantage, that it has a tendency to bring every legal difficulty ultimately through one tribunal, where a uniformity of principle may be expected in the application of the law, and, at the same time, stimulates the exertions of the subordinate judge, who, knowing that his proceedings will be revised, is careful to bring them as close as he can to those uniform principles of law which he knows that the court of appeal will apply. To accomplish this function of an appellate system, it is right that the investigation of the question at issue should have been exhausted in the inferior court, and that the court of appeal should have nothing before it which has not been there considered; for if the inferior court decide on one representation of circumstances, and the court of appeal on another, the public will lose the advantage of having the principle which was applied in the inferior reversed or affirmed in the superior tribunal.

The House of Lords is a court of appeal from all the chief civil and criminal courts in the United Kingdom, except the High Court of Justiciary in Scotland. It is only, however, in questions coming from the Equity Courts and the Court of Session in Scotland, that the term appeal is employed. The references from the common law courts have the name writ of error, which more characteristically expresses the function of a court of last resort from tribunals not suspected of partiality or tyranny, as being less an appeal from injustice than an application to correct the law administered by the court below. The origin of the appellate jurisdiction of the House of Lords was undoubtedly of that partly feudal and partly popular character already alluded to, which made the suitor seek justice from the high court of Parliament, when it was refused in the baronial court or even by the king's judges. Hence the lords exercised the mixed function of jurymen and judges, and, as in judgments on impeachment, the house might be influenced by private or party considerations, debating and dividing on the question before them. A revolution was silently accomplished, however, by which the function of reviewing the decisions of the courts fell entirely to the lawyers raised to the peerage, or to other judges brought in to give their aid; and the unprofessional lords now only attend to give the sanction of a quorum to the proceedings. The letters and memoirs, so late as Queen Anne's reign, show that party or personal influence and persuasion were employed to procure votes on appeals, as they have in later times on railway or other local bills. The last instance probably in which a strong division of opinion was manifested among the unprofessional lords was the celebrated Douglas cause in 1769, when the house was addressed by the Dukes of Newcastle and Bedford, but were led by the authoritative opinion of Lord Mansfield on the effect of the evidence; an opinion which, being treated rather as that of a political partisan than of a judge, was sharply commented on in a work of great talent written by Mr James Stuart, who had a deep personal interest in the cause. The case of O'Connell and others, brought up on writ of error from the Queen's Bench in Ireland, in 1844, may be said to have finally established the precedent, that the judgments of the House of Lords are to be given solely by the law lords. On that occasion there was a difference of opinion among the law lords themselves. The judgment of the majority was strongly against the political feeling of the government and of the peers as a body, while the law lords who carried the decision had been appointed by previous governments, opposed in politics to the existing cabinet. But all these temptations to a party vote by the unprofessional members were resisted.

Appeal.

The large proportional amount of the judicial work in the House of Lords caused by appeals from Scotland has been often noticed. It proceeds from two causes. In England there is a virtual appeal by writ of error from any one of the common law courts to the other two, not exemplified in Scotland. But there have always appeared to the disappointed Scottish litigant chances in his favour from his appeal lying to English judges against the Scottish judges who have decided against him. It has been said that such expectations have not always been disappointed, and that the English law lord has sometimes been unable so entirely to divest himself of professional prejudices, as to administer the law of Scotland without being biased by that of England. If the changes thus sometimes made in Scots law by such high authority have been improvements, yet it may justly be said that they should have been imparted by statute, not by judicial decisions.

Of old, in Scotland, there was something anomalous in an appeal to Parliament, as the Court of Session was, in its original constitution a committee of Parliament, for the performance of its judicial functions. In the reign of Charles II., however, the courts grew so intolerably corrupt that a determined effort was made to have their judgments overturned by an appeal, which was strictly of the old character of a cry for protection against flagrant injustice. It was called a "protest for remeid of law," and was inserted as one of the national claims in the petition of right at the Revolution. There was no allusion to an appeal system in the Treaty of Union; but the House of Lords, when appealed to against the judgments of the Court of Session, acted without hesitation. Many attempts were made, but without effect, to carry appeals from the supreme criminal courts in Scotland to the House of Lords.

A new tribunal has been lately erected for appeals from the Colonial courts, called the Judicial Committee of the Privy Council. It consists of the Lord President, the Lord Chancellor, and the holders of some other judicial offices when they are members of the privy council. Three members must be present to constitute an effective court, exclusive of the Lord President, who is the only unprofessional member of the court. It was constituted in 1833, and re-adjusted in 1851 (3d and 4th Will. IV., cap. 41, and 14th and 15th Vict., cap. 83). Appeal is generally the expression used for an application to revise summary judgments, as where the decision of one or two justices of peace may be referred to the quarter-sessions; and here, in some measure, the term retains its old meaning as a cry or appeal against injustice, since it is the remedy against the haste or ignorance with which it is not inaptly supposed that summary justice by unprofessional magistrates is administered. In Scotland the term appeal applies to the reference from the judgment of the sheriff-substitute to that of the sheriff.

In France the adoption of the nomenclature of the civil law has made the term, in its French shape of *appel*, of more comprehensive use to express references from a lower to a higher tribunal, than in this country. The general subject is briefly treated in the third book of the code of civil procedure.

The United States, in adopting the structure of the English law, brought with it the practice of appeal and writ of error, but the federal constitution and the jealousy of central power have practically restricted the operation of the system. By the constitution, the Supreme Court of the United States, is vested with "appellate jurisdiction, both as to law and fact, with such exceptions, and under such regulations, as Congress should make." It appears to be held, however, that this does not confer appellate jurisdiction, but only authorizes Congress to create it, so that it is presumed not to exist unless it be specially provided for and limited. In the words of Mr Kent, "If Congress had not provided any rule to regulate the proceedings in appeal, the Court could not exercise an appellate jurisdiction; and if a rule be provided, the Court could not depart from it. In pursuance of this principle the Court decided in *Clarke* v. *Bazadone*, that a writ of error did not lie to that court from a court of the United States territory north-west of the Ohio, because the Act had not authorzied an appeal or writ of error from such a court."—(*Commentaries*, i., 324.)

Appellant ‖ Appellation.

A peculiar and pernicious process which existed until a late period in English criminal law, received the name of appeal. It was a right of prosecution possessed as a personal privilege by an injured party, of which the Crown could not deprive him, directly or indirectly, since he could use it alike when the prisoner was tried and acquitted, and when he was convicted and pardoned. It was chiefly known in practice as the privilege of the nearest relation of a murdered person, and was generally employed when the public passions were roused against the accused, on account, not so much of the evidence against him as the atrocity of the crime. Thus, after Colonel Oglethorpe's inquiry and report on the London prisons, when, in 1729, Banbridge and the other jailors were acquitted on indictments for deficiency of evidence, they were hotly pursued by appeals of murder. In the case of Slaughterford, in 1708, the public indignation was roused by the atrocity with which the accused was charged with murdering the woman he had seduced. The evidence was very imperfect, and he was acquitted on indictment; but an appeal was brought, and on conviction he was hanged, as his execution was a privilege belonging to the prosecutor of which the crown could not deprive him by a pardon. In 1818 a parallel case occurred, when the appeal was ingeniously met by an offer of battle, since, if the appellee were an able-bodied man, he had the choice of the two ordeals, combat or a jury. This neutralising of one obsolete and barbarous process by another, called the attention of the legislature to the subject, and appeal in criminal cases, along with trial by battle, was abolished by 59th Geo. III., cap. 46. A curious inquiry into this subject will be found in "An argument for construing largely the right of an appellee of murder to insist on trial by battle," by E. A. Kendall. See Parliament. (J. H. B.)

APPELLANT, in *Law*, one who appeals.

APPELLATION, the name by which any thing is known or distinguished when spoken of. Nothing can be more foreign to the original meaning of many words and proper names than their present or vulgar appellations; frequently owing to the history of those things being forgotten, or an ignorance of the language in which they were expressed. Who, for example, would dream that the legal proclamation called "O yes," was a proclamation commanding the talkers to become hearers, being the French word *Oyez*, listen, retained in our courts ever since the law pleadings were held in French? Or would any person suppose that the headland on the French coast near Calais, called by our seamen Blackness, has been so entitled from its French name of *Blanc Nez*, or the *White Head-land?*

King Henry the Eighth having taken the town of Boulogne in France, the gates of which he brought to Hardes in Kent, where they are still remaining, the flatterers of that reign highly magnified this action, which, Porto Bello like, became a popular subject for signs; and the port or harbour of Boulogne, called *Boulogne Mouth*, was accordingly set up at a noted inn in Holborn. The name of the inn long outliving the sign and fame of the conquest, an ignorant painter, employed by a no less ignorant landlord to paint a new one, represented it by a bull and a large gaping human mouth; answering to the vulgar pronunciation of *bull and mouth*. The same piece of history gave being to the *bull and gate*, originally meant for Boulogne gate,

and represented by an embattled gate or entrance into a fortified town.

The *barber's pole* has been the subject of many conjectures; some conceiving it to have originated from the word *poll* or head, with several other conceits as far-fetched and as unmeaning; but the true intention of that party-coloured staff was to show that the master of the shop practised surgery, and could breathe a vein as well as mow a beard. The white band which encompasses the staff was meant to represent the fillet thus elegantly twined about it.

Nor were the *chequers*, at this time a common sign of a public-house, less expressive,—being the representation of a kind of draught-board called *tables*, and showing that there that game might be played. From their colour, which was red, and the similarity to a lattice, it was corruptly called the *red lettuce*, which word is frequently used by ancient writers to signify an ale-house.

The *Spectator* has explained the sign of the *bell-savage inn* plausibly enough, in supposing it to have been originally the figure of a beautiful female found in the woods, called in French *la belle sauvage*. But another reason has since been assigned for that appellation, namely, that the inn was once the property of Lady Arabella Savage, and familarly called *Bell Savage's Inn*, probably represented, as at present, by a bell and a savage or wild man, which was a rebus for her name; rebuses being much in fashion in the sixteenth century.

The *three gilt balls* so commonly hung out as signs at pawnbrokers' shops, by the vulgar humorously enough said to indicate that it is two to one that the things pledged are never redeemed, were in reality the arms of a set of merchants from Lombardy, who were the first that publicly lent money on pledges. They dwelt together in a street, from them named Lombard Street, in London, and also gave their name to another at Paris. The appellation of Lombard was formerly all over Europe considered as synonymous with that of usurer.

At the institution of yeomen of the guards, they used to wait at table on all great solemnities, and were ranged near the buffets. This procured them the name of *buffetiers*, not very unlike in sound to the jocular appellation of *beef-eaters*, now given them; though probably it was rather the voluntary misnomer of some wit, than an accidental corruption arising from ignorance of the French language.

The opprobrious title of *bum bayliffe*, so constantly bestowed on the sheriff's officers, is, according to Judge Blackstone, only the corruption of *bound bayliffe*, every sheriff's officer being obliged to enter into bonds and to give security for his good behaviour, previous to his appointment.

A *cordwainer* seems to have no relation to the occupation it is meant to express, which is that of a shoemaker. But *cordonier*, originally spelt *cordaunier*, is the French word for that trade; the best leather used for shoes coming originally from Cordova in Spain.

APPELLATIVE Names, in *Grammar*, in contradistinction to proper names, are such as stand for universal ideas, or a whole rank of beings, whether general or special. Thus, *fish, bird, man, city, river*, are common or appellative names; and so are *trout, eel, lobster;* for they all agree to many individuals, and some to many species.

APPENDINI, Francesco Maria, the author of a very valuable work in two volumes, 4to, entitled *Notizie Istorico Critiche sulle Antichità Storia e Letteratura di Ragusa;* but his earliest publication was an Illyrian Grammar. Appendini was born at Turin in 1768; and as a member of a religious fraternity, early sent to Ragusa. There he entered fully into the civil and literary history of his adopted country, which he discussed and illustrated with great success. When the French seized Ragusa, his merits were not overlooked by Napoleon, who placed him at the head of the Ragusan Academy; and when that little state fell into the possession of the Austrians, that government also appreciating his great merits, set him over the Normal Institution at Zara, an establishment for educating teachers for the various schools of the Illyrian provinces. He died in 1837, greatly esteemed and deeply regretted.—See Tipoldo, *Biografie.*

APPENZELL, a canton of Switzerland, the thirteenth in the confederation. It is a mountainous district in the north-east of Switzerland, entirely surrounded by the canton of St Gall. Of the chains of mountains which traverse it, some, especially in the south, attain a considerable elevation, that of Mount Sentis, the highest, being 8232 feet. Its principal river is the Sitter, besides which it is watered by several rivulets. It was at one time almost covered with pine and fir forests, abounding in game and wild animals; but in consequence of the extension of the population, these have much diminished. Peat and coal are abundant. From the general elevation of this canton the climate is cold and variable, but not unhealthy. It has an area of 152 square miles, with a population in 1850 of 54,869. The violent struggles which followed the Reformation occasioned its division into two parts in 1597—Inner Rhodes occupied by Roman Catholics, and Outer Rhodes by Protestants. Outer Rhodes comprehends about two-thirds of the canton, being its northern and western parts, and has a population of 43,599, almost all Protestants. Population of Inner Rhodes 11,270, almost all Roman Catholics. These two divisions have distinct democratic forms of government; each has a great council, the members of which are chosen by the people, and whose acts are all subject to approval by the general body of the people. Outer Rhodes sends two members to the national council, and Inner Rhodes one; the former contributing 772, and the latter 200 men to the federal army. The houses are distinguished by neatness and cleanliness, and are surrounded with gardens. Education, and the training of the young here, as throughout Switzerland, is much attended to. The inhabitants of Inner Rhodes are principally engaged in the rearing of cattle; those of Outer Rhodes in manufactures, especially cotton and linen goods, and embroidery. The capital of Inner Rhodes is Appenzell; of Outer Rhodes, Trogen.

Appenzell, the capital of Inner Rhodes in the above canton, is situated in a beautiful valley of the Sitter, seven miles south of St Gall. It has an old Gothic church, two convents, and a council-house. Pop. 3200, principally engaged in the linen trade.

APPETITE, in a general sense, the desire of enjoying some object supposed to be conducive to our happiness. This term is applied particularly to hunger, thirst, and the appetite of sex. Considered as principles of action, the appetites are distinguished by the following circumstances: —1. They take their rise from the body, and are common to us with the brutes. 2. They are not constant, but occasional. 3. They are accompanied with an uneasy sensation, which is strong or weak in proportion to the strength or weakness of the appetite.—See Stewart's *Philosophy of the Active Powers*, book i. chap. i.

APPIA Via, a way reaching from Rome through Capua to Brundusium, between 330 and 350 miles long. Appius Claudius, surnamed *Cæcus*, in the year of the city 441, carried it from the Porta Capena to Capua. (Livy, Frontinus.) It was afterwards carried on to Brundusium, but by whom, or when, is uncertain. It was laid with very hard stone, brought from a great distance, large, and squared (Diodorus); and it was so wide that several waggons could go abreast. What remains of it shows, that below the squared stones there were two other beds of prepared materials. The first, or lowest, is of rubble stones laid in mortar, the next is a bed

of gravel, both being about 3 feet in thickness. The breadth of this road is only 14 feet. Statius calls it *the queen of roads.* Its course is described by Horace, Strabo, and Antonine.

APPIAN, an eminent writer of the Roman history in Greek, under the reigns of Trajan and Adrian. He was of a good family in Alexandria in Egypt; whence he went to Rome, and there distinguished himself so well as an advocate, that he was chosen one of the procurators of the empire, and appointed to the government of a province. He did not complete the Roman history in a continued series, but wrote distinct histories of all nations that had been conquered by the Romans, in which he placed every thing relating to those nations in the proper order of time. Of all this voluminous work there remains only what treats of the Punic, Syrian, Mithridatic, and Spanish wars, with those against Hannibal, the civil wars, and the wars in Illyricum, and some fragments of the Celtic and Gallic wars. An excellent edition of Appian was published by Schweighæuser at Leipsic, in 1785, in 3 vols. 8vo. The extracts from the lost books are collected in this edition; the best edition of the text is that of Bekker, 1853.

APPIANI, the name of two eminent painters, who lived in our own times. Andrea was the best fresco painter of his age, and imitated the style of Coreggio. He was the pensioned artist to the kingdom of Italy. His best pictures are in the vice-regal palace at Milan, and in one of the churches of that city; where he was born in 1754, and died in 1814, of grief, it is said, for the loss of his patron and his pension. Francesco is said, by Lanzi, to be fully entitled as a fresco painter to notice in a history of the art. He was a pupil of Magatta, and had an agreeable style, as appears by his works at Perugia, where he principally lived. The same authority mentions that many of his easel pictures went to Britain. He was born in 1702, and died in 1792, aged 90; an instance of "vigour unexampled except in the case of Tiziano."

APPIUS CLAUDIUS, a Sabine by birth, one of the principal inhabitants of Regillum. His shining merit having drawn the envy of his fellow-citizens upon him, he retired to Rome with all his clan. Appius was admitted among the patricians, and was made consul with Publius Servilius Priscus in B.C. 495; but he was hated by the plebeians, being an austere opposer of their demands. The Claudian family continued long one of the most illustrious of the patrician families in Rome, and several in succession of the name of Appius supported the same stern character that distinguished their first founder.

APPLAUSE, an approbation of something, signified by clapping the hands, still practised in theatres. Applause, in antiquity, differed from acclamation, as the latter was articulate and performed with the voice, the former with the hands. Among the Romans applause was an artificial kind of noise made by the audience or spectators to express their satisfaction. There were three species of applause, denominated from the different noises made in them, viz., *Bombus*, *Imbrices*, and *Testæ;* the first a confused din, made either by the hands or the mouth; the second and third, by beating on a sort of sounding vessels placed in the theatres for this purpose. Persons were instructed to give applause with skill; and there were even masters who professed to teach the art. The proficients in this way let themselves out for hire to the vain-glorious among the poets, actors, &c., and were properly disposed to support a loud applause. These they called *Laudicœni* and Σοφοκλεις. At the end of the play a loud peal of applause was expected, and even asked of the audience, either by the chorus or the persons who spoke last. The formula was *Spectatores plaudite*, or *Valete et plaudite.* The plausores or applauders were divided into chori, and disposed in theatres opposite to each other, like the choristers in cathedrals, so that there was a kind of concert of applauses. The practice of keeping hired applauders (*claqueurs*) is still maintained in the French theatres.

APPLE. For the description of this fruit-tree, see HORTICULTURE.

Apples form a considerable article of commerce, and are imported to Britain chiefly from France and America. The quantity of raw apples imported from foreign countries in 1852 was 372,229 bushels, and from British possessions 2124.

APPLEBY, a small market and borough town of England, in the county of Westmoreland, of which it is the capital, 13 miles from Penrith. It is situated on a hill, which is crowned by a very ancient castle, and is almost surrounded by the river Eden, which is here crossed by a fine old stone bridge. It consists chiefly of one broad irregularly built street. Its principal buildings are the castle, two churches, market-house, town and shire halls, gaol, hospital for thirteen widows, and the grammar-school, which has six exhibitions at Queen's College, Oxford. It is governed by a mayor, twelve aldermen, and sixteen burgesses, and previous to the Reform Act, by which it was disfranchised, it sent two members to Parliament. The town possesses little trade, and its population is decreasing. In 1851 it was 883.

APPLICATION, in *Geometry*, is used either for division; for applying one quantity to another, whose areas, but not figure, shall be the same; or for transferring a given line into a circle or other figure, so that its ends shall be in the perimeter of the figure.

APPRAISER (from *ad*, to, and *pretium*, value), one who rates or sets a value upon goods, &c. It is practised by brokers of household furniture, to which set of men the word is chiefly applied; yet upholsterers and other brokers are employed, or even any person supposed to be skilled in the commodities to be appraised or valued. See AUCTIONEER.

APPREHENSION, in *Logic*, denotes the simple attention of the mind to an object presented either to our sense or our imagination, without passing a judgment or making an inference.

APPRENTICE (from *apprendre*, to learn), one who is bound by covenant to serve a tradesman or artificer a certain time, upon condition of the master's instructing him in his art or mystery.

By the common law, every person is left at liberty to follow whatever trade or employment may be agreeable to him. But as it was supposed that great injury would result to the public if unqualified persons were to exercise the various crafts and mysteries connected with the mechanical trades, it was specially provided, by the 5th Eliz., that no person should exercise any art or craft unless he had previously qualified himself for it by a regular apprenticeship, under a penalty of L.400 for every month. Considerable doubts were always entertained as to the trades to which this statute applied; and as the courts of law do not seem generally to have favoured the principle of the statute, their decisions tended rather to confine than to extend the restriction. It was at length agreed that the law was only applicable to such trades as existed at the time of passing the act, and to such also as implied some mystery or craft. The operation of the statute was also held to be limited to market-towns, it being supposed necessary, for the convenience of the inhabitants of country villages, that the same person should exercise different trades, even though he had not been regularly bred by a seven years' apprenticeship to each. These various limitations of the statute gave rise to many very absurd distinctions, which plainly showed how very unsuitable this antiquated law was to the present advanced state of the mechanical trades. It was found, for example, that a coachmaker could neither himself make nor employ journeymen to make his coach-wheels, but that it behoved him to buy them of a master wheelwright, this last trade having been

exercised in England before the 5th Eliz. But a wheelwright, though he has never served an apprenticeship to a coachmaker, might either himself make, or employ journeymen to make, coaches, the trade of a coachmaker not having been prohibited by the statute, as not being exercised in England at the time it was passed. All the great manufactures which, in modern times, have arisen throughout England—in Manchester, Birmingham, Sheffield, Wolverhampton—were on this account exempted from the restrictive operation of this law; and the perfection to which they have arrived seems a practical proof of its inutility for the encouragement of trade.

The effects of those restrictions imposed by the 5th Eliz. were at length felt to be so injurious, that, in the year 1813, petitions were presented to parliament from various manufacturing towns for a repeal of certain parts of this exceptionable statute; and the 54th Geo. III. was accordingly passed, by which all the penalties and prohibitions imposed by 5th Eliz. on those who should exercise any trade or mystery, unless qualified by six or seven years' apprenticeship, were repealed. That part of the statute was also repealed which enacted that no person should become an apprentice except in strict conformity to the provisions of the 5th Eliz., and which rendered all indentures contrary to this act null and void. In opposition to this, it was provided that all indentures or covenants which would otherwise be valid, should now be valid, anything in the 5th Eliz. to the contrary notwithstanding.

APPRENTICESHIP, the servitude of an apprentice, or the duration of his indenture.

Seven years seem anciently to have been, all over Europe, the usual term established for the duration of apprenticeships in the greater part of incorporated trades. All such incorporations were anciently called *universities*, which indeed is the proper Latin name for any incorporation whatever. The university of smiths, the university of tailors, &c., are expressions which we commonly meet with in the old charters of ancient towns. When those particular incorporations which are now peculiarly called *universities* were first established, the term of years which it was necessary to study in order to obtain the degree of master of arts, appears evidently to have been copied from the term of apprenticeship in common trades, of which the incorporations were much more ancient. As to have wrought seven years under a master properly qualified was necessary in order to entitle any person to become a master, and to have himself apprentices in a common trade; so to have studied seven years under a master properly qualified was necessary to entitle him to become a master, teacher, or doctor (words anciently synonymous), in the liberal arts, and to have scholars or apprentices (words likewise originally synonymous) to study under him.

Apprenticeships were altogether unknown to the ancients. The reciprocal duties of master and apprentice make a considerable article in every modern code. The Roman law is perfectly silent with regard to them. There is no Greek or Latin word which expresses the idea we now annex to the word apprentice—a servant bound to work at a particular trade for the benefit of a master during a term of years, upon condition that the master shall teach him that trade.

Dr Smith considers the institution of apprenticeships as a device by which trading corporations endeavour to confine to as few hands as possible the mystery of their craft, and by which, keeping the market always understocked with their particular sort of labour, they expect to regulate according to their discretion the price of such manufactures as they bring to market. He accordingly condemns all those laws which limit the number of apprentices to be taken by each master in particular trades, or which prescribe to apprentices a certain term of service before they are permitted to work as journeymen. The tendency of such laws, he observes, is to restrain the competition to a much smaller number than might otherwise be disposed to enter into the trade; the limitations of the number of apprentices restraining it *directly*, and a long apprenticeship restraining it *indirectly*, but as effectually, by increasing the expense of education. Long apprenticeships, or indeed any apprenticeship, for however short a term, Dr Smith considers quite unnecessary, as the nicest mechanical arts, such as the making of clocks and watches, contain, according to his theory, no such mystery as to require a long course of instruction. A few weeks, he calculates, or even a few days, would be sufficient to enable a mechanic to set to work in any of those trades; and if he were paid the full price for his work, he paying of course for such materials as he might spoil through awkwardness and inexperience, he imagines that he would learn his business more effectually, and be more apt to acquire habits of attention and industry, than when he works under a master who has a right to share in the produce of his labour.

It may generally be remarked, however, that, in his reasonings on these subjects, Dr Smith seems uniformly disposed to overrate the practical effect of those expedients by which corporations have been always endeavouring to secure special advantages for particular trades; and that his theory respecting apprenticeships is only a part of that more general theory by which he endeavours to show that the policy of Europe has always been to encourage the industry of the towns at the expense of that of the country; and that the effect of this policy has been to enable the merchants and manufacturers of the town, in bartering their produce for that of the country, to levy, for several centuries, an unjust and oppressive tax on the agricultural classes of the community. We know, however, that, according to the nature of human society, as it is so admirably explained in Dr Smith's work, monopoly can never succeed on so great a scale; and, on the same principle, we may rationally question, if the contract between the apprentice and his master were merely the device of corporations, whether it ever could have come into such universal use throughout Europe. The engagement by which the apprentice is bound to his master is his own voluntary act. He agrees to bind himself to work to his master at an inferior rate, on condition of receiving from his master the necessary instruction in his business. This instruction, Dr Smith asserts, may be given him in the course of a few days or a few weeks. It is well known, however, to every practical tradesman, or to any one acquainted with the nature of mechanical employments, that the instruction of three days or weeks would scarcely teach an apprentice the name of his tools, and that almost all the mechanical trades require throughout their various operations such nicety and exactness, that the necessary habits are not formed by the training of years, in place of weeks or days. It is for the troublesome superintendence of the apprentice during this period that the master exacts compensation, without which he would employ none but finished workmen. But he puts up with the awkwardness of his apprentice because he expects to be benefited by his labour after he shall be better instructed in his business; on the same principle that the farmer lays out his capital on the improvement of his land, in expectation of a future increase of produce. The contract of apprenticeship is thus a voluntary agreement between two parties for their mutual benefit, the result neither of law nor of the usages of petty corporations, but of circumstances. The law, indeed, takes cognizance of the contract, and enforces its fulfilment; and it may also have encumbered it with absurd regulations; but the contract itself stands independent both of law and usage, having its origin in the plainest principles of reciprocal expediency. There seems no reason, therefore, to class it with those artificial expedients which originate in the exclusive spirit of trading corporations.

Dr Smith appears also to have greatly overrated the effects of those laws, the object of which is to limit the number of apprentices who shall be reared to particular trades. No law of any corporation will ever be found in practice to impose any limitation on the number of apprentices who may be trained to a business. It will depend on the state of the business, whether it is advancing, stationary, or declining, what number of apprentices will be bred to it; and if, while a flourishing trade called for a continual supply of new hands, any corporation were to enact a law limiting the masters to such a number of apprentices as would barely keep up their present stock, a scarcity of hands would soon be felt, wages would rise, and the masters would soon be induced, by regard to their own interest, to rescind the law which imposed so great an inconvenience on themselves. But if the law is thus modified and accommodated to the state of the trade, it is a mere form. It imposed in reality no restraint, since it is always in the power of the masters to alter it whenever they feel that it interferes with their arrangements.

But though the law were even rigidly persisted in, it is evident that it would not permanently diminish the number of apprentices who would be bred to a business, since the consequence would be, that the workmen would turn masters, and each taking the full allowance of apprentices which the law permits, would soon train up an ample supply of hands. All those petty contrivances of corporations, therefore, though they may originate in the lowest mercantile jealousy, and though they may be exceedingly absurd, cannot materially disturb the general progress of things; and though they may harass individuals, their effect on the industry of a great country hardly deserves notice; their bad effects being corrected by those general causes on which society depends for completing its arrangements, in spite of the obstacles arising from the mistaken policy of legislators.—See Smith's *Wealth of Nations*, with Notes, and an additional volume of Dissertations, by David Buchanan. (D. B—N.)

The provision of the General Merchant Seaman's Act, 7th and 8th Vict. cap. 112, binding all vessels (except yachts) of 80 tons and upwards to carry a certain number of apprentices in proportion to their tonnage, was repealed by the Navigation Act, 12th and 13th Vict. cap. 29. The age of apprentices when bound is not material, provided they have completed their twelfth year; but no apprenticeship to the sea-service is binding after the apprentice shall have attained the age of twenty-one; when, or at the expiration of his apprenticeship, whichever shall first happen, his indenture and register-ticket are to be delivered up to him, under penalty of L.20. All the indentures of apprenticeship and assignments of sea apprentices are to be registered in the "General Register Office of Merchant-Seamen" in London, if the master shall be or reside there; or if at any other port, by the collector or comptroller of such ports. Any master or owner neglecting to deliver a counterpart, and cause the indenture or assignment to be registered within ten days, shall be liable to forfeit L.10 (G. M. S. Act, cap. 112, § 42). If, after a ship shall have proceeded on a voyage, the master shall permit any apprentice to quit, except for the purpose of entering the royal navy, such master shall be liable to forfeit L.20 (*Ibid.*); nor can he enter into that service without the consent of his master.—See Symon's *Law of Merchant Seamen;* the acts above mentioned; and the *Mercantile Marine Act.*

APPROACHES, in *Fortification*, are the *covered ways* by which the besieger tried to draw near a fortification, without exposing his men to the fire of the place. The covered way is formed by excavations advancing obliquely to the fortress, and the earth thrown out of the cut is collected between it and the works of the besieged, as an additional cover to the men; or where the ground is rocky, they are protected by baskets of earth, or bags filled with some soft material. See FORTIFICATION.

APPROXIMATION, in *Arithmetic* and *Algebra*, the coming nearer and nearer to a root, or other quantity sought, which cannot be found exactly by any known process.

APPULSE, in *Astronomy*, the approach of any planet to a conjunction with the sun or a star. It is a step towards a transit, occultation, conjunction, eclipse, &c.

APRIES, the Pharaoh Hophra of the Bible, was the 4th king of the 26th Egyptian dynasty, and succeeded his father Psammis about 595 B.C. According to Herodotus (iv. 159), he conquered the Tyrians in a naval engagement at Sidon, and re-established the Egyptian dominion over Syria. He carried his arms into Libya, but was defeated in an attempt upon Cyrene. His subjects revolted and proclaimed Amasis king, and in a battle which followed Apries was taken prisoner and strangled, B.C. 570.

APRIL (*Aprilis*), the fourth month of the year, according to the common computation; but the second according to that of the astronomers. It contains 30 days. The word is derived from *aperio*, I open, because the earth in this month begins to open her bosom for the production of vegetables.

A PRIORI and A POSTERIORI, philosophical terms, derived from a distinction of Aristotle between the order of nature and the order of human knowledge, that which is prior (πρότερον) in the one, being posterior (ὕστερον) in the other. With the followers of Aristotle, accordingly, a demonstration *a priori* is a proof from the cause to the effect, *a posteriori*, a conclusion from the effect to the cause.

The term *a priori* came afterwards improperly to be applied to any abstract reasoning from a given notion to the conditions which such notion involves, *e.g.*, to what have been called the *ontological* and *cosmological* proofs of the existence of God; the proof from experience (*e.g.*, the argument from design) being called *a posteriori.*

In modern philosophy, however, since the time of Kant (though the distinction may be traced in Hume), these counter terms are used to distinguish those elements of human knowledge which are native, necessary, and antecedent to experience, from those which are merely the data of experience. Thus, the truths of mathematics, founded on the intuitions of time and space are *a priori;* the facts of history, founded on experience, are *a posteriori.*

APRON, in *Naval Architecture*, is a piece of curved timber fixed behind the lower part of the stem, immediately above the foremost end of the keel.

APRON is also a name given to a platform or flooring of plank, raised at the entrance of a dock, against which the dock-gates are shut.

APRON, in *Gunnery*, a piece of lead which caps or covers the vent or touch-hole of a gun.

APSIS, in *Ecclesiastical Writers*, denotes an inner part in the ancient churches, wherein the clergy sat, and where the altar was placed. It is supposed to have been thus called because covered with an arch or vault of its own, by the Greeks called ἁψὶς, by the Latins *absis*. Apsis, in this sense, amounts to the same with what is otherwise called *choir*, *concha*, *camera*, and *presbyterium;* and stands opposed to the *nave* or body of the church.

APSIS is more particularly used for the bishop's seat in ancient churches. This was peculiarly called *apsis gradata*, because raised on steps above the ordinary stalls. It was also denominated *exedra*, and in latter times *tribune*.

APSIS was also used for a reliquary or case, wherein the relics of saints were kept. It took the name *apsis* from its being round or arched at the top, or perhaps from the place where it was kept. The *apsis* was commonly placed on the altar; it was usually of wood, sometimes also of gold and silver, with sculptures, &c.

APSIS, in *Astronomy*, a term used indifferently for either of the two points of a planet's orbit, where it is at the greatest or least distance from the sun or earth; and hence the line connecting those points is called the line of the *apsides*. The word is Greek, and derived from ἅπτω, *I connect.* The apsis, at the greatest distance from the sun, is

called the *aphelion*, and at the greatest distance from the earth the *apogee;* while that at the least distance from the sun is termed the *perihelion*, and at the least distance from the earth the *perigee*.

APT, an arrondissement in the department of Vaucluse in France, extending over 453 square miles, or 290,288 acres. It is divided into five cantons, and 50 communes. Pop. in 1851, 55,916.

Apt (*Apta Julia*), capital of the arrondissement of that name, situated in a rich valley on the left bank of the river Calavon, and surrounded by old walls. It is the seat of a bishop, and has a court of primary jurisdiction, a society of agriculture, and a college. Population in 1851, 5699, engaged in the manufacture of woollen and cotton stuffs, confections, brandy, earthenware; also in silk-spinning, blanching wax, &c.; besides which they export grain, wines, truffles, almonds, fruits, and cattle. Apt, one of the most ancient cities of Gaul, was restored by Julius Cæsar, who built across the river a fine bridge of one arch, which still exists. The Gothic cathedral is of high antiquity, and the town presents various objects of antiquarian interest. Long. 5. 23. 47. E. Lat. 43. 52. 29. N.

APTERYX (from α, priv., and πτέρυξ), a singular genus of absolutely wingless birds found in New Zealand. See Ornithology.

APTHANE, a title anciently given to the higher degrees of nobility in Scotland. See Thane.

APULEIUS, Lucius, a Platonic philosopher, well known by his performance entitled *Metamorphoses, or the Golden Ass.* He was born at Madaura, a Roman colony in Africa, about the year 128, and died probably about the end of the reign of the second Antonine. He studied first at Carthage, then at Athens, and afterwards at Rome, where he learned the Latin tongue without the help of a master. He was a man of a curious and inquisitive disposition, especially in religious matters. This prompted him to take several journeys, and to enter into various religious societies. He spent almost his whole fortune in travelling; so that on his return to Rome, when he was about to dedicate himself to the service of Osiris, he had not money enough to defray the expense attending the ceremonies of the reception, and was obliged to pawn his clothes to raise the necessary sum. He supported himself afterwards by pleading at the courts; and being a great master of eloquence, and of a subtile genius, he was entrusted with many important causes. But he benefited himself more by marrying a rich widow named *Pudentilla.* This marriage, however, drew upon him a troublesome lawsuit. His wife's relations, pretending that he had made use of sorcery to gain her heart and money, accused him of being a magician before Claudius Maximus, proconsul of Africa. Apuleius found no great difficulty in making a successful defence. His *Apology*, which is still extant, contains some very curious details. Apuleius was indefatigable in his studies, and composed many works, some in verse, and others in prose; but most of them have been lost. He took great pleasure in declaiming, and was heard generally with applause. The citizens of Carthage erected a statue to him, and several other cities did him the same honour.

The editions of his works have been very numerous; the first and rarest was printed at Rome in 1469, and an excellent one was published at Leyden in 1786–1823, in 3 vols. 4to. This edition was begun by Oudendorp, and published after his death by Ruhnkenius and Bosscha. A very elaborate edition of his whole works was published at Leipzig in 1842, by G. F. Hildebrand. His principal pieces, besides the celebrated fiction of the *Golden Ass*, are his *Apology*, entitled *Oratio de Magia;* fragments of speeches, entitled *Florida;* three books of philosophy, entitled *De Habitudine Doctrinarum et Nativitate Platonis;* and a curious treatise, *De Deo Socratis.*

APULIA, a subdivision of ancient Italy. It had Lucania on the south, Samnium on the west, the river Tifernus on the north, and the Adriatic on the east. It formed a part of the Japygia of the early Greeks. It was successively under the Romans, the Goths, the Lombards, and the Saracens. The Normans of Sicily conquered it, and it now, as *Puglia*, forms the Neapolitan provinces of Capitanata, Bari, and Otranto.

APURE, a large river of Columbia in South America, 520 miles long, and forming one of the principal affluents of the Orinoco.

APURIMAC, a considerable river of South America, which rises in the Andes near the northern extremity of the Lake of Titicaca, about 16° south latitude, and after receiving several large tributaries, pours itself into the Marañon, about 5° south latitude; before which it has changed its name to Rio Ucayali. Its whole course is about 500 miles.

APUSCIDAMUS, a lake of Africa mentioned by Pliny (xxxi. 2), on whose surface even the heaviest bodies were said to float. Similar stories were related of several other lakes and fountains.

APYCNI (*Soni*), ἄπυκνοι (φθογγοί), among the ancient Greek writers on music, meant sounds not crowded together by small intervals. In particular, those three of the fixed or unalterable sounds of the ancient system which were called *Proslambanomenos*, *Nete synemmenôn*, and *Nete hyperbolæôn.* See Euclid's *Harmonic Introduction;* edit. Meibomius, pp. 6, 7.

APYROUS (α, priv., and πῦρ), a word applied to denote that property of some bodies, by which they resist the most violent fire without any sensible alteration. Apyrous bodies ought to be distinguished from those which are refractory. Refractory substances are those which cannot by violent heat be fused, whatever other alteration they may sustain. But a body, properly speaking, apyrous, can neither be fused by heat, nor undergo any other change. Diamonds were long thought to be possessed of this property; but experiments have shown that diamonds may be entirely dissipated or evaporated by heat, and are therefore not entitled to be ranked among apyrous substances. Perhaps there is no body in nature essentially and rigorously apyrous. But it is sufficient that there be bodies apyrous relatively to the degree of fire which art can produce, to entitle them to that name.

AQUA, the commercial name in Scotland for malt spirit.

Aqua, a term frequently met with in the writings of physicians, chemists, &c., for certain medicines or menstruums, in a liquid form, distinguished from each other by peculiar epithets, as—

Aqua Fortis, a name given by artists to nitric acid of a certain strength, on account of its dissolving power.

Aqua Marina, a name by which the jewellers call the beryl, on account of its sea-green colour.

Aqua Regia, a compound of nitric and muriatic acid, in different proportions, according to the purpose for which it is intended. It is usually made by dissolving in nitric acid either sal ammoniac or common salt, both of which are combinations of muriatic acid with alkali.

Aqua Secunda, aqua fortis diluted with much pure water. It is employed in several arts to clear the surface of metals and certain stones.

Aqua Tofana, called also *Aqua della Toffanina* or *Aqua della Tofa*, from its inventress Tofana,—*Aqua del petesino*,[1]—*Aquetta di Napoli*, or simply *Aquetta*, a poi-

[1] Lanzoni *Opera*, vol. i. p. 69. Lausannæ, 1738, 3 vols.

Aqua Tofana.

sonous liquor which was used to a very great extent at Naples and Rome during the latter half of the 17th century. Gmelin[1] says that more people were destroyed by it than by the plague, which had prevailed a short time before it came into use; and Garelli, chief physician to the emperor, wrote to Hoffmann that Tofania confessed she had used it to poison more than 600 persons. This he learnt from the emperor himself, to whom the whole criminal process instituted against her was transmitted.[2]

It is to be regretted that Garelli, who had such an authentic source of information, has not given us some details of the infamous Tofana or Tofania, as the little that we know of her rests upon the authority of travellers, and is evidently exaggerated, and sometimes irreconcilable with established facts. She was a Sicilian by birth, and resided first at Palermo, and then at Naples. When she began to exercise her horrible profession, is nowhere stated; but it will presently appear that it must have been at a very early age, and before 1659. She was extremely liberal of her preparation, chiefly, it is said, to ladies tired of their husbands; and the better to conceal the nature of her gift, it was put up in small flat phials, inscribed *Manna of St Nicholas of Bari*, ornamented on one side with an image of the saint, that it might pass for a liquid said to drop from his tomb at Bari, which was in great request on account of the medicinal virtues ascribed to it. Nor is it ascertained how long she carried on her murderous practices with impunity and undiscovered. Labat[3] says, that when he was at Civita Vecchia in 1709, the viceroy of Naples, then Count Daun, made the discovery. It was long before she was secured, as she was extremely cautious, and often changed her abode or retired into convents. At last she was betrayed, and, although in a convent, was seized and carried to the Castel del Uovo, where she was examined. Cardinal Pignatelli, then archbishop of Naples, indignant at the violation of a religious sanctuary, threatened to excommunicate the whole city if she was not delivered up to him; and the people were ready to rise. But the sagacious viceroy caused a report to be spread that she and her accomplices had determined upon the same day to poison all the springs in the city, the fruits brought to market, and the public granaries. The manœuvre succeeded. The credulous people were now clamorous for her punishment, and saw with satisfaction the persons whom she accused of having purchased her *Aquetta* taken from the churches and monasteries. Some of inferior birth were executed publicly, those of higher rank secretly in prison; and the whole city resounded with the praises of the viceroy, whose energy had saved it from general destruction. A kind of compromise was entered into with the cardinal; in consequence of which, after being strangled, her body was thrown at night into the court of the convent, by way of testifying some respect for the rights of the church. But the reverend traveller must have either been misinformed as to the actual execution of this Medea, or she must have been resuscitated; for Garelli expressly says that she was alive in prison at Naples when he wrote to Hoffmann, not long before 1718; and Keysler, who visited Naples in 1730,[4] likewise asserts that she was then living in prison, and that few strangers left the city without going to see her. He describes her as a little and very old woman.

The Roman ladies very quickly availed themselves of Tofania's discovery; for it was remarked in 1659, that many husbands died when they became disagreeable to their wives; and several of the clergy also gave information that, for some time past, various persons had confessed themselves guilty of poisoning. This led to the detection of a society of young married women (who had for their president an old woman of the name of Hieronyma Spara, a pretended fortune-teller), as the perpetrators of these murders. On being put to the torture they all confessed except Spara, who seemed to rely upon the protection of powerful individuals whom she had formerly served. But she was left to her fate, and was hanged along with her assistant, one Gratiosa. Others were afterwards hanged, or whipt and banished. Spara, who was a Sicilian, had acquired her knowledge from Tofania at Palermo.[5]

Pope Alexander VII., immediately on the discovery and punishment of those who dealt in poison in his capital, published an edict forbidding the distillation of aqua fortis, or the purchase of any of its ingredients, without the permission of the government; which Gmelin considers as an artifice to mislead the people as to the real composition of the poison, or as originating in the absurd nomenclature of the chemists of former times, who called arsenic concrete aqua fortis. But the prudence of the Pope was rendered fruitless; for we are informed by Gayot di Pitaval (*Causes Celèbres*, vol. i. p. 317, Amsterd. 1764), on what authority he does not state, that Tofania's fatal secret was disclosed by the indiscretion of the judges at Naples, to whom she had made confession of her crime. The whole city soon knew that she employed in its composition a very common herb, and that its preparation was otherwise easy; and in this way the art of poisoning became very common in Naples, where, Keysler says, it was still secretly practised when he visited Italy; and Archenholz,[6] who was there in 1780, states, that Aqua Tofana was then in use, although its composition was only known to a few; but Joseph Frank, who was long professor in Pavia, and has written a work on toxicology (*Handbuch der Toxicologie*, p. 168, Wien, 1803), regards this as an unfounded calumny, and asserts that it no longer exists or is heard of.

Aqua Tofana is described as being as limpid as rock water, and without taste, and hence it could be administered without exciting suspicion. The Abbé Gagliani adds,[7] that there was not a lady in Naples who had not some of it lying openly on her toilet among her perfumes, in a phial known only to herself.

It was generally believed that the effect of this poison was certain death, and that it could be so tempered or managed as to prove fatal in any determinate time, from a few days to a year or upwards. Four or six drops were reckoned a sufficient dose, and they were said to produce no violent symptoms, no vomiting, or but very seldom;

no pains, convulsions, inflammation, or fever;[1] but only a feeling of indisposition, without any very definite symptoms, except sometimes inextinguishable thirst: the victim, however, sunk into a languid state, and his weakness increased daily. Disgust at all kinds of food, and weariness of life, succeeded: the nobler organs were then attacked, the lungs were wasted by suppuration, and death closed the miserable scene. This termination was the more certain, that the true cause of these symptoms was not at first suspected, and the remedies commonly prescribed rather aggravated the evil. Indeed, even when known, no treatment was of any avail, although a Dr Branchaletti, according to Keysler, wrote a book on its remedies, until it was discovered by accident that lemon-juice, when very early administered in large doses, sometimes proved effectual (Bertholinus), after which Keysler tells us that the poison fell into some disrepute.

Various accounts of the composition of this detestable liquor have been given. Abbé Gagliani, and more lately Archenholz, state it to be a preparation of cantharides and opium; but this is perfectly inconsistent both with its appearance and effects. By no preparation can the smell and taste of opium, if the quantity be sufficient to produce any effect, be concealed; and the acrimony of cantharides is equally connected with its activity. The one of these drugs is highly stimulant, the other a sedative, and neither of them capable of remaining latent in the system, or injuring the constitution. Erndtel,[2] but without any probability, has conjectured that the chief ingredient was lead: Halle (*Die deutchen Giftpflanzen*, Berlin, 1703) believes that it was prepared from the frothy saliva gathered round the mouth of a person tortured to death. Garelli, on the contrary, positively asserts it to have been nothing but a solution of crystallized arsenic in a large quantity of water, with the addition, for some unknown reason, of a very innocent herb, the *Antirrhinum cymbalaria*. The same account is given by Bertholinus, Lobel (*Der freymüthige Heilkunstler*, Berlin, 1786), Plenk (*Toxicologia*, p. 335), Haller,[3] Molitor (*Commerce Lit. Noric.* 1737, p. 132), and Möhsen,[4] and is received by the most judicious systematic writers, as Gmelin and Hahnemann. (*Ueber die Arsenikvergiftung*, p. 35. Leipzig, 1786, 8vo.) Wildberg,[5] however, considers its composition to be unknown.

From Italy this poison seems to have found its way to Paris. In 1672 Godin de Sainte Croix, an adventurer, who lived in a scandalous intimacy with the Marchioness Brinvilliers, was suddenly killed by suffocation, as it is said, in consequence of the falling off of a mask of glass, which he wore to protect him from the fumes of certain chemical operations about which he was employed. As he had no known relations, his effects were examined by a public officer, and among them was found a casket, containing many packets of poisonous articles, sealed up in a mysterious manner, together with a kind of last will, directing the whole to be delivered to the marchioness, and, in case of her having predeceased him, to be burnt unopened. This led to the discovery of his having been instructed in the art of preparing poison by an Italian, called Exili, with whom he had become acquainted when confined in the Bastile; and of his having furnished the marchioness with the means of poisoning her father and her two brothers, besides others on whom she tried the effect of her preparations. One of these afterwards was called from her by the name *Eau de Brinvilliers*. She is also said to have employed a powder called *Poudre de Succession*.[6] La Chaussée, who had been valet to Sainte Croix, was convicted of being accessory to these murders, and was broken alive on the wheel. The marchioness herself, who had escaped to Liege, was also seized; and her execution, which took place on the 17th of July 1676, is described with revolting levity by Madame de Sevigné in a letter to her daughter of that date.

The practice of poisoning, however, did not seem to terminate with the death of this infamous woman; and a particular court called *Chambre des Poisons*, or *Chambre Ardente*, was established in 1679, to endeavour to put an end to it. In consequence of the investigations which took place in it, many persons, some of the highest rank, especially the Duc de Luxembourg, were implicated. More than 40 persons were at one time confined in the Bastile; but it was ascertained that almost all of them had been guilty of no crime, but were merely the dupes of a few impostors, who pretended to raise spirits, foretell future events, and to possess many secrets of a similar nature. Two women, La Vigoreux and La Voisin, with the brother of the former, and a priest called Le Sage,[7] pretended fortune-tellers, were convicted of being dealers in poison, and burnt alive on the 22d of February 1680; some others were hanged, and others acquitted. This closed the proceedings of this inquisitorial court, which has been accused of being a political engine, contrived to serve the purposes of Louvois and the Marchioness de Montespan. Voltaire, however, admits that the crime of poisoning infected Paris from 1670 to 1680.

Concerning the effects of the *Eau de Brinvilliers*, Pitaval tells us (p. 271) that the marchioness's father experienced violent effects from the poison,—extraordinary vomiting, insupportable pain at the stomach, and great heat in the bowels. He died soon after his return from his country-seat to Paris. The brothers and five other persons were all taken ill, and affected with vomiting, after partaking of a tart at dinner. On their return from the country to Paris, the brothers had the appearance of persons who had been long ill; and after suffering, the one for two, and the other for three months, from nausea and vomiting, they died extremely emaciated, and as it were dried up, without fever, though experiencing a burning sensation in the stomach. On opening the bodies, the stomach and duodenum were black and tender, and the liver gangrenous and burnt. Madame Sevigné relates that the marchioness often poisoned her husband, that she might marry Sainte Croix; but that the gallant, having no desire for a wife of her disposition, as often gave the poor husband an antidote. She is also said to have attempted to poison her sister, but did not succeed; and

[1] Bertholinus alone enumerates very violent fever as its first effect. See J. J. Wepferi *Historia Cicutæ Aquaticæ*, p. 372. Lugd. Bat. 1733, 8vo.

Stentzell *De Venenis terminatis et extemporaneis, quæ Galli* les Poudres de Succession *vocant.* This powder was probably an arsenical composition; but it was supposed by Erndtel and Haller to be acetate of lead, and by Brendel (*Institutiones Medicinæ Legalis*, Halæ, 1768) to consist of lead and bismuth.

[7] Voltaire, *Siècle de Louis XIV.* chap. xxvi.

that she was in the habit of trying the effects of her poisons on the poor, and even on the patients in the Hotel Dieu, under pretence of charitably supplying them with biscuits. But Voltaire positively denies this horrible imputation, and says that she never attempted the life of her husband, who overlooked a connection of which he was the cause.

The information concerning the nature of the *Eau de Brinvilliers*, derived from the examination of Sainte Croix's famous casket, is not satisfactory. It contained poisons enough to have killed a whole community; besides opium, lunar caustic, antimony, and vitriol, more than 75 lbs. of corrosive sublimate, and two bottles of a liquid like water, with a sediment in one. The clear liquid was probably his real poison; as none of the other substances could have been given so as to produce death, without instantly being detected by their abominable taste; but what this liquid was, we can now only conjecture; for its examination, as reported by Pitaval, shows that the physicians at that time had not the slightest notion of the mode of detecting arsenic even in substance, much less in solution; and accordingly, although both the liquor and powder killed the animals to which they were given, it is candidly admitted that the poison of Sainte Croix surpassed the art and capacity of the physicians, and that it baffled all their experiments to discover its composition. We have, however, no doubt that arsenic was the only active ingredient of all these pretended secret poisons, as it is the only substance capable of explaining all the credible circumstances related of them. From the mode of administering them in small but repeated and perhaps increased doses, there was some foundation for the belief that they could be given so as to kill in any determinate time, while their failing in any instance to produce death was easily accounted for by supposing antidotes to have been administered. But although the progress of knowledge has proved that there is no such thing as such antidotes, it has on the other hand, by rendering the detection of poison easy and certain, put a stop for ever to the trade of *poisoner*, and, what is perhaps of equal importance, to the general alarm and cruel punishment of individuals, which have often resulted from natural deaths being ascribed to poison. It is not because we know less, but because we know a great deal more than our forefathers, that the art of secret poisoning seems to be lost. (A. D.)

AQUAMBOE, a country in the interior of the Gold Coast of Africa, extending 20 miles along the banks of the Rio Volta, which separates it from Aquapim, and reaching 100 miles inland. The natives are haughty, turbulent, and warlike; and their territory, though fertile, is indifferently cultivated. Like all the countries in the interior from the Gold Coast, it is now entirely subject to the preponderant power of the king of Dahomey.

AQUAPENDENTE. See FABRICIUS.

AQUAPIM, a kingdom of considerable extent in the interior of the Gold Coast of Africa, immediately behind Acra, and having on the other side Aquamboe. This country is said to vie in beauty and fertility with any in the world. It is finely diversified with wooded hills and highly-cultivated valleys, the former having usually towns and villages situated on their summits. The people are obedient to their chiefs, mild and gentle, and are chiefly employed in agriculture, which they practise with considerable diligence.

AQUARIANS, Christians in the primitive church who consecrated water in the eucharist instead of wine. This they did under pretence of abstinence and temperance, or because they thought it universally unlawful to eat flesh or drink wine. Epiphanius calls them *Encratites*, from their abstinence; St Austin, *Aquarians*, from their use of water; and Theodoret, who says they sprung from Tatian, *Hydroporastatæ*, because they offered water instead of wine. Besides these, there was another sort of Aquarians, who did not reject the use of wine as unlawful; for they administered the eucharist in wine at evening service; but in their morning assemblies they commonly used water, lest the smell of wine should discover them to the heathens.

AQUARII, in *Antiquity*, slaves who supplied the women's baths with water, called sometimes *Aquarioli*, and held in great contempt (*Juv.* vi. 331, *Fest.* p. 19). The inspectors of the conduits or water-pipes were likewise called *Aquarii*.

AQUARIUS, the WATER-BEARER, in *Astronomy*, the 11th sign of the zodiac. It is marked thus, ♒. The poets feign that Aquarius was Ganymede, whom Jupiter ravished under the shape of an eagle, and carried away into heaven to serve as a cup-bearer in the room of Hebe and Vulcan; whence the name. Others hold that the sign was thus called because when it appears in the horizon the weather usually proves rainy.

AQUATINTA ENGRAVING, so called from its near resemblance to water-colour drawings, is of modern invention, and was much practised several years ago; and though for some time past it has been less in fashion, it is a branch of the art which is still pursued to some extent.

It is performed in a variety of ways; but the most approved is by covering or immersing the copper-plate in a solution of resinous matter, rendered so in rectified spirits of wine, and by working or drawing the object which is wished to be represented, upon the plate, with a prepared pigment, commonly called the bursting ground. These solutions and grounds are made of a variety of substances, described in recipes at the end of this article.

The work is generally commenced by etching, or tracing the outline upon the plate with an etching needle or other sharp instrument, which being done, and the etching ground removed, the plate must be made particularly clean and free from grease, with whitening and water. The plate is then to be placed in a flat tin or earthen vessel, in an inclined position, and the resinous solution or ground (No. 1, &c.) poured quickly upon it from the top to the bottom, so that the superfluous ground may run off, and be preserved for after-use in a vessel so placed as to receive it. Should the subject to be engraved be a landscape, it will be advisable to allow the ground upon the plate to dry in the inclined position, because the granulation of the shade or tint has a tendency to be closer and finer in proportion as it is nearer the top of the plate; and in this way the sky is represented by the finest grain at the top, and the foreground by the coarsest at the bottom of the plate. Should the subject require an equality of tint or grain, it will be procured by reversing the inclined position of the plate backwards and forwards as quickly as possible after the ground has been poured on it. The spirit of wine will very speedily evaporate, leaving the plate dry, with the ground upon it ready for work; but in order to render it more secure, it may be held over a clear fire, with the back of the plate next the coals until the resin of the ground is a little heated, and so fixed to the plate more completely. Care must, however, be taken, in this operation, not to melt the resinous granulations so much as to cause them to unite into solid masses.

The design is now to be drawn upon the plate with the bursting ground (No. 10, &c.), exactly in the same manner as any water-colour drawing is set about: every part where a tint is required is to be covered over with the bursting ground, and the lights alone left untouched with it. When this composition is quite dry, take a broad camel-

hair pencil, such as is used for painting skies, and go over the whole surface of the plate with the varnish (No. 13). The plate is now to be surrounded with a border of wax (14), so as to retain the aqua fortis. When the varnish is dry, as much clean water must be poured upon the copper as can be contained within the border wax, and in about 15 minutes the bursting ground will burst open the varnish, and leave the aquatinta ground ready for being bit in with the diluted acid. The bursting away of the bursting ground may be aided with the help of a clean camel-hair pencil or goose-quill feather; but if the composition be properly made this will not be necessary. The plate may now be said to be ready for the first tint being bit in with the aqua fortis, which must be allowed to remain upon it until the shade is seen to be of a proper colour, when the acid must be poured off, and the plate cleaned with water, to prepare it for the second tint; which is to be accomplished in the same manner as described for the first; and thus the greatest softness of shade, and the utmost sharpness of touch in the foreground or sky, may be attained. A pair of bellows may be used to dry the plate more quickly between the bitings with the aqua fortis, and so prevent the copper from becoming corroded by the water. From the description above given, it will be obvious that in some cases the bursting ground will not be required, and that the lights alone will need to be stopped out with the varnish;—such as in fleecy white clouds, the high lights upon metallic substances, &c.; all which practice will soon suggest to the artist.

Before we proceed to describe some other modes of performing this operation, we may remark, that when very fine grounds are required, it is customary only to bite in the lightest shades with the first granulation, and then to clean the plate and lay on a second, or even a third and fourth ground, at various stages of the work. But it must be held in mind, that in proportion as the grounds are multiplied, the granulations are subdivided, and their rich grain lost; while at the same time the work is rendered less serviceable, by its casting off a smaller number of impressions.

Should the bursting ground not flow on the plate freely out of the camel-hair pencil, in consequence of the plate being greasy, it may be washed with very weak aqua fortis before commencing. If the weather should be very cold, it is difficult to obtain a good ground; on which account it will be advisable to heat the apartment with a stove to a moderate summer heat.

Dust Grounds are prepared by covering the plate with powders of various mixtures, and fixing them by holding it over a clear fire; and the operation of biting in the subject with the aqua fortis, and the painting of the objects upon the plate, may be performed in the manner above described, and either with or without the bursting grounds. The powders may be applied to the surface of the copper in a variety of ways. As good a mode as any is to cover over the top of a small box with one or two layers of muslin, and dust the powder through these layers of muslin equally upon it. For this purpose the plate will require to be a little greasy, that the powder may adhere the more readily; and when the whole surface is covered, give the plate a sharp stroke upon the back, that the superfluous particles may be disengaged.

Madame Prestel's ground, celebrated for its fineness, is produced in the following manner: The plate is placed with its face upwards in a box, about six inches deep, covered with a lid: at one end introduce through a circular hole the small end of a hair-dresser's powder machine, filled with finely pulverized resin, and work it till the plate is completely covered with the powder, which fix over a clear fire, as already described.

Spirit Grounds.

No. 1. *Resin Ground.*—One quart of double rectified spirits of wine, and ten ounces of common resin: when dissolved, a variety of granulations will be obtained by adding spirits of wine to this solution.

No. 2. *Burgundy pitch ground.*—One quart of spirits of wine and ten ounces of Burgundy pitch: the coarseness or fineness of this, as well as the former ground, is influenced by the greater or less quantity of spirits in which the pitch is dissolved.

No. 3. *Mastic ground.*—Four ounces of gum mastic to one pint of spirits of wine: this, if made a month before being used, will be found to be a good ground.

No. 4. *Animi ground.*—Eight ounces of gum animi to one quart of spirits of wine.

No. 5. *Frankincense ground.*—Twelve ounces of gum frankincense to one quart of spirits of wine.

No. 6. *Turpentine varnish ground.*—One fourth of a pint of turpentine varnish to three fourths spirits of wine makes a curious granulated ground.

All these compositions may be mixed one with another, or even two or three may be combined; and the results, interesting in consequence of the variety of granulations which will be produced, and, as mentioned before, the coarseness and fineness, will vary in proportion to the quantity of spirits which are used.

Dust Grounds.

No. 7. Equal parts of asphaltum and fine transparent resin, finely powdered separately, and afterwards completely mixed together.

No. 8. Gum sandarach finely powdered.

No. 9. Transparent resin finely powdered. These powders may be so pulverized as to produce fineness or coarseness of granulation.

Bursting Grounds.

No. 10. Half a pound of treacle, half an ounce of isinglass, and eight ounces of gum arabic, in no more water than will just dissolve them. This should be set by for a week, shaking it up twice a day: when used, a little must be poured into a cup, and as much lamp black, burnt cork, or *terra de sienna*, ground as finely as possible, added to it as will give it both body and colour. Should it be too stiff to work, add a little water.

No. 11. Half a pound of treacle, four ounces of white sugarcandy, and one ounce of gum arabic, dissolved in a little water, at least a week before using.

No. 12. Half a pound of West Indian white sugar, an ounce and a half of isinglass, and one ounce of gum dragon, dissolved in as much malt liquor of any kind as will make them liquid; set them on the fire until all are well melted, and, when cool, the composition may be used immediately. These two last recipes may be coloured with the same substances as No. 10.

No. 13. The varnish used for covering over these bursting grounds is common turpentine varnish, thinned down with turpentine to the proper consistency required.

No. 14. Border-wax is composed of equal parts of shoemaker's resin and bees-wax.

The preceding is the method for prints of one single tint. But if different colours are to be expressed, there will be required as many different plates, each plate having only the part etched upon it which is designed to be charged with its proper colour; unless (as may happen in particular subjects) some of the colours are so distant from each other as to allow the printer room to fill them in with his rubber without blending them; in which case

Aqueduct. two or more different colours may be printed from the same plate at once. Where different plates are necessary, a separate one, having a pin in each corner, must be provided as a sole or button to the aquatinta plates; and these again must be exactly fitted, having each a small hole in their corners for passing over the pins of the sole; the said pins serving the double purpose of retaining the plates successively in their due position, and of directing the printer in placing the paper exactly on each plate so as not to shift; by which means each tint or colour will be exactly received on its proper place. A landscape or similar subject, however, may be printed off at once in the different proper colours, by painting these upon the plate. In this case the colours must be pretty thick in their consistence; and the plate must be carefully wiped in the usual way after the laying on of each tint, as well as receive a general wipe upon its being charged with all the tints. For more particular information upon this art, see the third edition of Green's *Complete Aquatinta*. (W. H. L.)

AQUEDUCT, a conduit or channel for the conveyance of water. It is derived from *aqua*, water, and *ductus*, a conduit. It is applied more particularly to those structures of masonry which have been erected for the conveyance of water across valleys, to which, however, we would rather give the name of aqueduct bridges, extending the term aqueduct to the whole conduit or channel by which the water is conveyed from one place to another. The conveyance of water for the supply of large cities has in all ages formed a very important object of public economy; and aqueducts of various kinds have been in use for this purpose from the earliest times, the remains of which have been examined by travellers in different parts of the East. Pococke describes a work of this kind erected by Solomon, for conveying water from the pools and fountains near Bethlehem to Jerusalem. "The aqueduct," he says, "is built on a foundation of stone; the water runs in round earthen pipes about 10 inches diameter, which are cased with two stones, hewn out so as to fit them, and they are covered over with rough stones well cemented together; and the whole is so sunk into the ground on the side of the hills, that in many places nothing is to be seen of it." But it was in the luxurious capital of Rome that the system of aqueducts was brought to the greatest perfection, and carried to an extent which has never been equalled even in modern times, and has justly excited admiration both from the number and magnificence of the works themselves, and the prodigious quantities of water which by these means were continually poured into the city. These aqueducts extended, some of them 30, 40, and even 60 miles from the city, in one continued covered channel of stone, carried by arcades over the widest and deepest valleys, and by tunnels running in many parts for miles through mountains and through the solid rock. "If we consider attentively," says Pliny, "the quantities of water brought into the city for the use of the public, for baths, for fish-ponds, for private houses, for artificial lakes, for gardens in the neighbourhood of the city, and for villas; if we look also at the works which have been constructed for forming a regular channel for the waters—arches raised up, mountains pierced with tunnels, and valleys filled up to a level; it must be acknowledged that there is nothing in the whole world more wonderful."

Aqueducts of Ancient Rome.

For about 400 years after the building of the city the Romans were contented with the waters of the Tiber, or what was drawn from wells or from fountains in the city and its neighbourhood. But the great increase of the population rendering a more ample supply desirable, the censor Appius Claudius was the first to introduce an aqueduct to convey the waters of distant springs into the city. About thirty-nine years after this, M. Curius Dentatus brought in an additional supply from the neighbourhood of Tibur. These examples were afterwards followed by various other public men, as the wants of the city rendered new supplies necessary. Among these were Papirius, Crassus, Marcius, Agrippa, and Augustus; and most of the succeeding emperors, even Tiberius, Claudius, Caligula, Nero, and Caracalla, esteemed it an honour to connect their names with such great and useful works. Aqueduct.

Frontinus, who was appointed curator of the aqueducts by the emperor Nerva, has left the most ample account of them. According to him, there were nine great aqueducts by which the city was supplied. Five more were added by Nerva, and the number was afterwards augmented by succeeding emperors to twenty. Of these, the most remarkable were the Aqua Appia; the Old and New Anio; the Aqua Martia, which also conveyed the Aqua Julia and the Aqua Tepula; the Aqua Virginia; and the Aqua Claudia. The *Aqua Appia* was so named from the censor Appius Claudius, by whom it was constructed in the 442d year of Rome. It commenced in a field near the Via Prænestina, between the 6th and 8th mile-stones, made a circuit of 780 paces to the left, and then proceeding by a deep subterranean channel of more than 11 miles, entered the city at the Appian Way by the Porta Capena, and delivered the main body of its waters into the Campus Martius. The *Old* and *New Anio* were so called from their bringing into Rome the waters of that river. The former began above the Tiber, at the 30th mile-stone, and consisted mostly of a winding channel, carried through an extent of about 43 miles. The latter, constructed under Nero, took a higher level, running 7543 paces above ground, and then through a subterranean passage of 54,267 paces in length. The *Aqua Martia*, which owed its formation to Quintus Martius, rose from a spring distant 33 miles from Rome, made a circuit of three miles, and afterwards forming a vault of 16 feet diameter, it ran 38 miles along a series of arcades at an elevation of 70 feet. It had openings perforated at certain distances for discharging the collected air, and at different places deep cisterns, in which the water settled and deposited its sediment. On this account it was remarkable for its clear green colour, and is celebrated by Pliny for its coolness and salubrity. The *Aqua Julia* and the *Aqua Tepula* were brought to Rome by the same aqueduct as the *Aqua Martia*, but on higher levels. The whole aqueduct above the arcades was divided into three stories or channels. In the uppermost flowed the Aqua Julia, in the second the Aqua Tepula, and in the lowest the Aqua Martia. From the ruins of this combined fabric, which still subsist, it appears to have been a very superb structure. The *Aqua Virginia* was constructed by Agrippa, who laboured to improve and beautify Rome, and who, according to Pliny, formed in one year 70 pools, 105 fountains, and 130 reservoirs. It commenced at a very copious spring, in the middle of a marsh, at the distance of eight miles from the city, and ran about 12 miles, passing through a tunnel of 800 paces in length. The *Aqua Claudia*, begun by Nero and completed by Claudius, took its rise 38 miles from Rome. It formed a subterranean stream $36\frac{1}{4}$ miles in length, ran $10\frac{3}{4}$ miles along the surface of the ground, was vaulted for the space of three miles, and supported on arcades through the extent of seven miles, being carried along as high a level as to supply all the hills of Rome. It was built of hewn stone, and still continues to furnish the modern city with water of the best quality, which has hence procured it the name of *Aqua Felice*.

In all these aqueducts the channel for the waters was carried with a regular declivity from the one end to the

Aqueduct. other of the aqueduct, and such as was sufficient to carry the water easily along. In some cases the declivity, had the line been carried straight forward, would have been too great; it was therefore made to take a circuitous route, winding along the sides of the hills, and prolonging the length of the channel so as to reduce the degree of descent, and cause the water to run gently along. The whole of the channel was regularly built of stone or brick, and arched above to cover in the channel, excepting in those places where it was cut out of the solid rock. Along all the valleys and water-courses which lay in the way it was elevated by a series of arches, all raised to the level of the conduit, resting on massy pillars, and all built in the most solid and substantial manner, with brick, and often with hewn stone. The sketches of Roman aqueducts in Plate XLIV., taken from Fabrettus, will give a better idea than any description, of the manner in which the work was executed. Sometimes there was only a single arch, as in the two middle figures; sometimes, again, where the conduit was to be elevated higher, as in the right-hand figure, a double row of arches was raised, one above the other, for greater strength and security. The figure on the left hand shows two conduits or aqueducts carried in different levels along the same building. The upper one is the New Anio, the lower is the Aqua Claudia. When we consider the labour and difficulties attending the construction of such arches and arched channels of masonry, the spirit and enterprise which could have undertaken such works as are above enumerated, undaunted by the expense, or any of the other obstacles which lay in the way, appear astonishing. In this country, where bridges, canals, and other water-works have been carried to a great extent and perfection, we consider an aqueduct of six or eight arches a work of no small extent and importance. What would we think, then, of the aqueduct of the New Anio, extending 6½ miles in one continued series of arches, many of them upwards of 100 feet high! If we allow a similar number of arches in the length, we shall have in all more than 600; and yet this is nothing compared with the aqueduct of the Aqua Martia, extending 38 miles, and containing in all nearly 7000 arches. Even an aqueduct bridge of five or six miles in length appears incredible; and yet how can we otherwise translate Frontinus, where he states the lengths of all the aqueducts, and how much was above or under ground, and how much was built in arches? Of the New Anio, for instance, he says its conduit was 63 miles 700 paces in length. Of this 49 miles 200 paces consisted of a subterranean stream, and 9 miles 400 paces were above ground, of which last the higher part consisted of "substructionibus aut opere arcuato," in several places of great length; and nearer the city, at the 7th mile-stone, consisted of "substructione" 609 paces, and "opere arcuato" 6 miles 491 paces; and he adds, "These arches are the highest of any, being raised in some parts 109 feet." The term *substructio* probably means a conduit built by opening up the surface of the ground and then covering over the building with earth, as we do in such works at this day. But the term *opere arcuato* can only refer to a continued series of arches, and certainly conveys a vast idea of the extent and magnitude of such works.

The total quantity of water delivered into Rome by these aqueducts was altogether astonishing, and quite beyond what we have any conception of now, for either comfort or luxury. Strabo said truly, that whole rivers flowed through the streets of Rome. According to Frontinus, the nine earlier aqueducts delivered daily 14·018 quinaria, which corresponds to nearly 28 millions of cubic feet; and when all the aqueducts were in operation, the quantity must have amounted to 50,000,000 cubic feet; which, reckoning the population of the city at that time at a million, would give 50 feet daily, or 7 hogsheads to each individual. This is more than ten times the supply of London, which is now reckoned to be quite profuse.

Aqueducts of Modern Rome.

Of the modern aqueducts in Rome the principal are the Aqua Felice, the Aqua Virginia, and the Aqua Paulina. The first was constructed by Sixtus V. It commences at Palæstrina, about twenty-two miles from the city, and discharges itself at the Fontana di Termini. The Aqua Paulina was repaired by Pope Paul V. in the year 1612. It divides itself into two principal channels, one of which supplies Mont Janiculum, and the other the Vatican and its neighbourhood. It is conveyed from the district of Bracciano, about twenty miles distant; and three of its five streams are not inferior to small rivers. According to the calculation of Prouy, these three aqueducts, with some additional sources, deliver in twenty-four hours 5,305,000 cubic feet. This, among a population of 130,000, gives about 40 cubic feet for each individual, which is nearly equal in proportion to the supply of ancient Rome in the period of its utmost splendour.

Aqueducts of the Roman Empire.

But the system of aqueducts was not confined to the capital of Rome. It was gradually extended throughout the provinces of that vast empire; and every city and considerable town had its conduits and aqueducts for supplying it with water, many of which still remain to attest the magnificence with which these works were carried on. In Plates XLIV. and XLV. we have given a view of some of these. The first is the remains of one of the principal aqueduct bridges in the aqueduct of Antioch. It is a work of great magnitude and height, but a very rude structure. The lower part consists almost entirely of solid wall, and the upper part of a series of arches with very massy pillars. It appears, however, to be a Roman work; and there are remains of another aqueduct on a lower level, and of an older date. The water to Antioch was brought from a distance of four or five miles, from a place called Battelma, which Pococke thinks was the very spot where Daphne stood. Several springs, one of which was so large as to turn several mills, were conveyed in channels of hewn stone, and united in one main stream, which was thence conveyed along the surface of the ground in a similar channel. Across all the rivulets and valleys it was raised on arches or aqueduct bridges, some of which are very lofty, and the principal is the one exhibited in the plate, extending upwards of 700 feet in length, and upwards of 200 feet high in the deepest part. From the remains of the aqueduct in the island of Mytilene, represented from Pococke in the same plate, this appears to have been also a magnificent work. It was built of gray marble rusticated. It is much superior in point of skill to the aqueduct of Antioch, the arches being carried in two ranges throughout the building. It extended about 500 feet in length, and was about 70 or 80 feet high at the deepest part.

Aqueduct of Pyrgos.

The aqueduct or aqueduct bridge of Pyrgos, near Constantinople, forms a portion of the extensive hydraulic works with which that capital was supplied with water after it became the seat of empire. They are described by Andreossy in his voyage to the Black Sea, and account of the Thracian Bosphorus. It is a grand work, very remarkable both in design and execution, and affords a fair specimen of the style of such structures among the Romans in the middle ages. It consists of two branches, one of which only is seen in elevation in the plate; the other stood nearly at right angles to this, and is seen partly on the plan; it was hence called the Bended or Crooked Aqueduct, to distinguish it from another termed the Long Aqueduct, which was situated near the sources of the

waters. The branch seen in elevation extends 670 feet in length, and is 106 feet in height at the deepest part. It is composed of three rows of arches, those in each row increasing in width from the bottom to the top—an arrangement very properly introduced with the view of saving materials without diminishing the strength of the work. The two upper rows consisted of arches of semicircles, the lower of Gothic arches; and this circumstance serves to fix the date of the structure, as these last were not introduced until the 10th century. The breadth of the building at the base was 21 feet, and it diminished with a regular batter on each side to the top, where it was only 11 feet. The base also was protected by strong buttresses or counterforts, erected against each of the pillars. The other branch of the aqueduct was 300 feet long, and consisted of 12 semicircular arches.

This aqueduct serves to convey to Constantinople the waters of the valley of Belgrade, one of the principal sources from which the city is supplied. These are situated on the heights of Mount Hæmus, the extremity of the Balkan Mountains, which overhangs the Black Sea. The water rises about 15 miles from the city, and between three and four miles west of the village of Belgrade, in three sources, which run in three deep and very confined valleys. These unite a little below the village, and then are collected into a large reservoir. After flowing a mile or two from this reservoir, the waters are augmented by two other streams, and conveyed by a channel of stone to the Crooked Aqueduct. From this they are conveyed to another, which is the Long Aqueduct; and then, with various accessions, into a third, termed the Aqueduct of Justinian. From this they enter a vaulted conduit, which skirts the hills on the left side of the valley, and crosses a broad valley two miles below the Aqueduct of Justinian, by means of an aqueduct with a double row of arcades of a very beautiful construction. The conduit then proceeds onward in a circuitous route, till it reaches the reservoir of Egri Kapan, situated just without and on the walls of the city. From this they are conducted to the various quarters of the city, and also to the reservoir of St Sophia, which supplies the seraglio of the grand signior. The Long Aqueduct is more imposing by its extent than the Crooked one, but is far inferior in the regularity of design and disposition of the materials. It is evidently a work of the Turks. It consists of two rows of arcades, the lower being 48 in number, and the upper 50. The whole length was about 2200 feet, and the height 80 feet. The Aqueduct of Justinian is a very excellent work, and without doubt one of the finest monuments which remain to us of the middle ages. It consists of two rows of large arcades in the pointed style, with four arches in each. Those of the lower story have 52 feet of span, the upper ones 40 feet. The piers are supported by strong buttresses, and at different heights they have little arches passing through them, which relieve the deadness of the solid pillar. The length of this aqueduct is 720 feet, and the height 109 feet. This aqueduct, though it bears the name of Justinian, was probably erected in the time of Constantine.

Besides the waters of Belgrade, Constantinople was supplied from several other principal sources, one of which took its rise on the heights of the same mountains, three or four miles east of Belgrade. This was conveyed in a similar manner by an arched channel, elevated when it was necessary on aqueduct bridges, till it reached the northern parts of the city. It was in the course of this aqueduct that was constructed the contrivance of the *souterasi* or hydraulic obelisks described by Andreossy, and which has excited some attention, as being an improvement on the method of conducting water by aqueduct bridges. "The souterasi," says Andreossy, "are masses of masonry, having generally the form of a truncated pyramid or an Egyptian obelisk. To form a conduit with souterasi, we choose sources of water, the level of which is several feet higher than the reservoir by which it is to be distributed over the city. We bring the water from its sources in subterranean canals, slightly declining until we come to the borders of a valley or broken ground. We there raise on each side a souterasi, to which we adapt vertically leaden pipes of determinate diameters, placed parallel to the two opposite sides of the building. These pipes are disjoined at the upper part of the obelisk, which forms a sort of basin, with which the pipes are connected. The one permits the water to rise to the level from whence it had descended; by the other, the water descends from this level to the foot of the souterasi, where it enters another canal under ground, which conducts it to a second and to a third souterasi, where it rises and again descends, as at the last station. Here a reservoir receives it and distributes it in different directions by orifices of which the discharge is known." Again he says, "it requires but little attention to perceive that this system of conducting tubes is nothing but a series of syphons open at their upper part, and communicating with each other. The expense of a conduit by souterasi is estimated at only one fifth of that of an aqueduct with arcades." We really cannot perceive any advantage in these pyramids, further than as they serve the purpose of discharging the air which collects in the pipes. For if the water is to be conveyed in pipes across the valley, what other purpose can these columns possibly serve? They are in themselves an evident obstruction, and the water would flow more freely without any interruption of the kind. In regard to the leaden pipes, again, they would have required, with so little head pressure as is stated, to be used of very extraordinary dimensions to pass the same quantity of water as was discharged along the arched conduits. There is something, therefore, which would require explanation in this account of Andreossy regarding these pyramids, or else he has misunderstood the nature of them when he says that they supply advantageously the place of the aqueducts or arches. A train of pipes properly laid, and of proper dimensions, might do this; but what advantage the pyramids possess further than to answer the purpose of air-cocks, is not very apparent.

The other principal source from which Constantinople is supplied, is from the high grounds six or eight miles west of the town, from which it is conducted by conduits and arches, in the same manner as the others. The supply drawn from all these sources amounts, according to Andreossy, to 400,000 cubic feet per day; about two thirds of a foot to each person of a population of 600,000. The charge of the water-works at Constantinople belongs to a body of 300 Turks and 100 Albanese Greeks, who form almost an hereditary profession.

Aqueducts of Metz, Nismes, and Segovia.

Of the aqueducts which still remain as relics of Roman grandeur, the most remarkable are, the aqueduct of Metz; the aqueduct of Nismes, or the Pont du Gard; and the aqueduct of Segovia in Spain. "The aqueducts of Rome," says Montfaucon, "were without doubt wonderful on account of their great length—arcades continued over the space of 40 or 50 miles; their great number, with which the Campagna of Rome was filled on every side: all this surprises us. But it must be confessed that if, without considering the total extent, we only look at any of the parts which remain round Rome, there is nothing that approached the aqueducts of Metz, of Nismes, or of Segovia." The aqueduct of Metz is represented in Plate XLV. Nearly the half of it, it will be observed, has been carried away; but there still remain a great num-

Aqueduct.

ber of arches, and enough to give an idea of the extent of the whole. It extended across the Moselle, a very considerable river, and very broad in this place; and served to convey the delicious waters of the Gorse to the city of Metz. These waters, according to Meuripe, in his history of the bishops of Metz, printed in 1634, were so abundant that they furnished water for floating the vessels every time that a naval fight was to be exhibited. They were collected into a reservoir, and from thence conducted by subterraneous canals constructed of hewn stone, and so spacious that a man could easily walk in them upright. They then passed the Moselle by means of the aqueduct, which was situated about six miles from Metz, and from thence were conducted under ground in stone channels, similar to the others, to the city, to the baths, to the place of the sea-fight, and all over the city. Judging from the drawing, this aqueduct seems to have been nearly 1000 feet in length, the arches 50 feet high at the deepest part, and 50 in number. They formed only one series, the height not requiring a double row. They were so well built and cemented together, that, excepting the middle part, which the descent of ice down the river has in the lapse of ages carried away, they have resisted, and will continue to resist, the effects of time and of the most violent seasons.

The Pont du Gard was executed by the Romans in the reign of Augustus, and was then merely an aqueduct for bringing the waters of the fountain of Hure to Nismes. It was composed of three rows of arches filling up the valley between two mountains, between which ran the river Gardon. The first row comprehended six arches, each 60 feet span, excepting one, which was the largest, and was 75 feet span; the second row contained 12 arches of the same span as the first; and the third had 36 little arches, on the top of which was the channel for conducting the water. This bridge exhibits a decided improvement and superiority over all the other Roman aqueducts, in the lightness and striking boldness of its design. The arches are wider, and the piers in proportion lighter, than any other structure of the kind previously constructed; and had the same principle been extended so as to have formed only a single row from top to bottom, it would have equalled in the skill and disposition of its materials (circumstances in which the Roman works were almost universally wanting) any of the more judicious and elegant structures of modern times. About the year 1740, this bridge, being of no more use as an aqueduct, was converted into a road-way, by widening it, or rather building in a manner another bridge to the side of it, having all the arches of the same span and dimensions. The execution of the work was attended with considerable difficulties, but these were all successfully overcome by the French engineer Pitot.

The aqueduct of Segovia, according to Culmenares, who travelled in Spain, and has written the history of Segovia, may be compared with the most wonderful works which antiquity has transmitted to us. There still remain of it 159 arches, all built with large stones, and without any cement. There are two rows of arches, one above the other, and the whole height of the edifice is 102 feet. It runs quite across the town, and passes over the greater part of the houses which lie in the hollow.

French Aqueducts.

In modern times various aqueducts have been formed after the manner of the Romans, particularly in France. The most remarkable are those which were constructed in the reign of Louis XIV., at vast expense, for conducting water from Marly to Versailles. Of these the famous aqueduct bridge of Maintenon, which was erected for conveying the waters of the river Eure to Versailles, is without doubt, in point of magnitude and height, the most magnificent structure of the kind in the world. In Plate XLV. we have given a view of a portion of this work, on the same scale as the other aqueducts here represented. Had the whole been delineated on the same scale, it would have extended to four times the breadth of the plate. It extends about 4400 feet in length, being nearly seven eighths of a mile, and upwards of 200 feet in height, and contains 242 arcades, each divided into three rows, forming in all 726 arches about 50 feet span. Of the subterranean aqueducts in France the finest is that of Arcueil, which serves to conduct water to that village. It is 44,300 feet in length, or upwards of eight miles, extending from the valley of Arcueil to the castle at the gate of St Jaques, all built of hewn stone. It is about six feet in height, and has on each side a foot-path 18 inches wide; it has a declivity of one foot in 1300. Another aqueduct of this kind is that of Rocquancourt, part of the system which brings water to Versailles; it is 11,760 feet in length, or upwards of two miles, and a declivity in its whole course of only three feet. In some parts of its course it was necessary to make excavations 80 or 90 feet deep, which rendered the execution very difficult.

The great waterworks that supply the city of Marseilles with the water of the Durance, by a canal about 60 miles in length, are among the boldest undertakings of the kind in modern times. This canal, begun in 1830, and not yet completed (1852), has already cost above L.2,000,000 sterling. It is conveyed through three chains of limestone mountains by forty-five tunnels, forming an aggregate length of 8½ miles, and across numerous valleys by aqueducts; the largest of which, the Aqueduct of Roquefavour, over the ravine of the River Arc, about 5 miles from Aix, surpasses in size and altitude the ancient Pont du Gard. The immense volume of water, which passes at the rate of 198,000 gallons per minute, is carried across as in the old Roman aqueducts by a channel of masonwork. The height of this aqueduct is 262 feet, and its length 1287. The number of cubic yards of masonry contained in it is 57,000; the total cost has been L.151,394.

Aqueduct of the Ganges.

One other aqueduct of recent construction is worthy of notice. In those parts of British India where the fall of rain is scanty and uncertain, recourse is had to artificial irrigation, and the waters of many of the rivers of the country have been rendered available for this purpose by means of public works constructed by the government. Of these the most important is the Ganges Canal, which traverses the north-western provinces of Bengal, and distributes over their vast area nearly the whole volume of the waters of the Ganges. See Ganges. The canal begins at the point where the river issues from the mountains and enters the plains of Bengal. About twenty miles from its source, the line of the canal crosses the valley of the Solani River, and the works for effecting the transit are designed on a scale worthy of the undertaking. The valley is between two and three miles in width. An earthen embankment is carried across, raised on an average between 16 and 17 feet above the surrounding country, and having a width of 350 feet at its base, and 290 feet in the upper part. This embankment forms the bed of the canal, which is protected by banks 12 feet in depth and 30 feet wide at the top. To preserve these banks from the effects of the action of the water, lines of masonry formed into steps extend on each side throughout their entire length. The Solani River is crossed by an aqueduct 920 feet long, having side walls 8 feet thick and 12 deep, the depth of the water being 10 feet. The water of the canal passes through two separate channels. That of the River Solani flows under fifteen arches, having a span of 50 feet each, constructed in the most substantial manner and springing from piers resting on blocks of masonry sunk into the bed of the river. The cost of the aqueduct was upwards

Aqueduct.

of L.160,000. In grandeur of design, solidity of construction, and, above all, in extensive utility, it may challenge competition with any similar work in the world.

Modern improvements; introduction of iron pipes.

Within the last century, the invention and improvement of the manufacture of cast iron has completely changed the mode of conducting water into cities, by the introduction of cast-iron pipes instead of the stone conduits of former times. These pipes can now be formed of almost any dimensions, and united together into a continued series, so closely as to prevent the escape of the water, even under a violent pressure arising from the altitude of the fountainhead. They enable us, therefore, to take advantage of and give effect to that grand principle in hydrostatics, that the fluid element tends continually to a level, even though it be confined in the smallest or most complicated system of pipes; so that however low it be carried in any valley, or to whatever distance, still it will rise on the opposite side to the original altitude of the fountainhead—a principle which is most important indeed in such works, seeing that by it we are not restricted, as the Romans were, almost to a perfect level in the line of the conduit. We have seen that, for the purpose of attaining this level or very gentle declivity all along the conduit, they were under the necessity of raising it by arcades continued in one unbroken series, frequently 30 or 40 miles in extent; and, in addition to this, often prolonging the length of the track by a circuitous route, turning and winding for miles out of its course, for the very purpose of increasing its length.

But the use of pipes enables us to dispense with these long arcades all raised nearly to the same level with the fountainhead; because the conduit may be varied in its level to any extent, and still will rise at last to its original altitude. The pipes, therefore, are merely laid all along the surface of the ground, with a cover of 2 or 3 feet of soil to place them beyond the reach of frost. To prevent, however, the frequent or abrupt alternations of rise and fall, any sudden inequalities in the ground are equalized by cuttings and embankments, but not to anything like the extent that would be required to raise the whole to a level. This, therefore, forms a capital improvement in the method of conducting water, and the greatest indeed which has ever been made in this important branch of practical mechanics. That it was not introduced by the Romans, is not to be ascribed, as many have done, to their ignorance of the hydrostatic principle, that the fluid would rise to a level in the opposite branches of the same train of pipes. Professor Leslie has shown that they were well acquainted with this principle, and has moreover obtained from Italy a portion of a leaden pipe, supposed to have been used in the baths of Caracalla, which sets this matter at rest. But, from the low state of the arts at that period, they were unable to give effect to the principle. They had not the means of fabricating pipes of such a magnitude as would have been required for the enormous quantities of water consumed in Rome, and at the same time of strength sufficient to withstand the pressure from the fountainhead. Lead was the only material that could be used by them for the purpose; and besides the enormous thickness that so weak a material would have required, and the impracticability of their forming them, and uniting them together endwise, they were too well acquainted with the tendency of lead to render the water unwholesome by its poisonous impregnation. The use of cast iron was quite unknown. There remained, therefore, no resource but in the aqueducts, which, though attended no doubt with vast expense, and requiring great enterprise, as well as both skill and patience, were yet attainable by these means, and formed when completed a simple and very perfect mode of effecting the object. Hence arose all those works above described which have since excited such astonishment. Now, however, when the manufacture of cast iron has been brought to such perfection, and methods contrived for uniting perfectly together all the pipes into one connected train, this improved system has been universally adopted.

Croton Aqueduct.

The Croton aqueduct, by which the city of New York is supplied with water, may be regarded as the most magnificent work of the kind executed in modern times. It was commenced in 1837, and completed in 1842, at an expense of 8,575,000 dollars, the distribution pipes costing 1,800,000 dollars additional. Its length from the Croton lake to the receiving reservoir is $38\frac{1}{4}$ miles. The Croton lake, which is formed by the Croton Creek, a small stream of wholesome water falling into the Hudson, covers 400 acres, and contains a body of water of about 500,000,000 gallons. To the valley of the Harlem river, a distance of 33 miles, the aqueduct is built of stone, brick, and cement, arched over and under, 6 feet 3 inches wide at the bottom, 7 feet 8 inches at the top, and 8 feet 5 inches high; and capable of discharging 60,000,000 gallons per day. It is carried over the Harlem valley in iron pipes laid upon a magnificent bridge 1460 feet long, constructed of arches 114 feet above high-water mark at Yorkville. These pipes pass into the receiving reservoir, which is 1826 feet long and 836 feet wide, covering an area of 37 acres, and capable of containing 150,000,000 gallons. Hence, to the distributing reservoir, a distance of $2\frac{1}{4}$ miles, the water is conveyed by a double line of iron pipes 3 feet in diameter. This second reservoir is 420 feet square and 44 feet above the streets, with a capacity of 20,000,000 gallons,—whence the water is conveyed through the city by about 170 miles of pipe principally from 6 to 12 inches in diameter.

Edinburgh water-works.

The works undertaken by the Edinburgh Water Company in 1819 were probably the most complete and perfect of the time. They were designed by Mr Jardine, the then engineer of the company, and carried out under his superintendence in a style quite worthy of the city, and offering, both in the general design and in all the details, a model of propriety and skill in this species of hydraulic architecture. The Crawley springs were conducted by an aqueduct into a covered cistern at a point about 7 miles distant from Edinburgh, and a supply from the stream called the Glencorse Burn, conveyed by an open-work tunnel from about a mile and a half westward. This tunnel is in some places upwards of 30 feet deep, and the valley through which it passes, consisting entirely of gravel, acts as a filter through which the water descends and percolates, all solid matter being intercepted in its passage to the tunnel from whence it is delivered into the cistern, and conveyed to Edinburgh by a chain of pipes varying from 20 to 15 inches of interior diameter, without being exposed to the light of day. From the numerous undulations of the surface, the fall of the pipe is not uniform. Abrupt inequalities, however, were removed by cutting and embanking. Towards the northern termination of the line the pipe is carried through a tunnel of 2160 feet in length and about 70 or 80 feet under the surface of Heriot's Green. In crossing the Grassmarket it forks off by one branch to a reservoir in the Castlehill, and by another about 120 feet under the reservoir, through a tunnel 740 feet in length, cut through the rock of which the ridge leading to the Castle is composed. Branches were laid through all the principal streets.

The pipes are in lengths of $9\frac{1}{2}$ feet each, and were tested before being laid by a pressure equal to a vertical column of 800 feet of water. The joints are what are termed spigot and faucet. Cocks for the discharge of air accumulating in the pipes are placed at the summits of all the considerable elevations; and in the hollows are placed sluice cocks for the purpose of running off sand or other solid matter which may collect in the pipe. It is capable of delivering 253·56 cubic feet of water per minute into the reservoir at the Castlehill.

The formation of the Compensation Reservoir, was un-

Aqueduct. doubtedly the greatest work of hydraulic engineering of its day. It was designed and completed by Mr Jardine, and with the then limited experience of contractors and workmen in the construction of similar works, its successful completion does great honour to the genius and perseverance of the engineer. It has been twice enlarged, and now forms an artificial lake extending over an area of 46 imperial acres.

In 1843 the Company obtained the authority of Parliament to bring in the Black Springs and those of Listonshiells and Bavelaw. These springs are situated on the northern margin of the Pentlands; the Black Springs fully 9 miles, those of Bavelaw upwards of 10, and the Listonshiells between 12 and 13 miles distant from Edinburgh, in a direction early south-west by west. The Black Springs vary from ten cubic feet per minute to as high as 240. The Listonshiells and Bavelaw from 135 to 170. The quality of these waters is nearly uniform, and of great purity and excellence.

In the autumn of 1847, the springs of Bavelaw and Listonshiells, about 40 in number, were made available by being conveyed in clay pipes into a stone cistern at a place called Westrigg, about 12 miles distant from Edinburgh. They are thence conveyed for nearly five miles through an aqueduct to a point at the south-west end of Torphin Hill, and thence to Edinburgh by an iron pipe of 16 inches interior diameter. Compensation to the millowners on Bavelaw Burn and Water of Leith was provided by the construction of two reservoirs at Threepmuir and Harlaw, capable of containing about 68,000,000 of cubic feet. These reservoirs form one continuous chain, with not more than 30 feet of difference of level between them when full, and together occupy an area of fully 200 acres.

In the same year the Company constructed a new reservoir in the Glencorse valley, at a place called Loganlea; about a mile to the westward of the Compensation reservoir already referred to; two more on the northern side of the Pentland ridge at Clubbiedean and Torduff; another on the site of two old ones which had been long disused, in a flat and hollow part of the hill to the south of Bonally.

Glencorse reservoir increased its capacity from 46,242,045 to 55,160,409 cubic feet. The Loganlea reservoir contains 18,801,858; the Clubbiedean, 9,836,000; the Torduff, 17,821,459, and the Bonally, 8,000,000 cubic feet. The total storage in these reservoirs is 109,619,786 cubic feet, and their capacity is estimated to be equal to a supply of 350 cubic feet per minute for a period of four months without rain.

The delivery of water over a great part of the years 1851 and 1852 has been upwards of 520 cubic feet per minute, and estimating the population dependent on them for a supply, including the town of Leith, to which a supply was extended in 1826, and Portobello, which was supplied in 1851, at 190,000, even the present limited supply is equal to nearly 25 gallons per head per day of that population. When the whole works are completed and in full operation, this supply will not only be considerably augmented, but will be made secure.

Filters on a large scale, and on the most modern principle, have been provided at Glencorse for the purification of the water that may be taken out of the burn.

The works, under the Act of 1847, were designed by Messrs Rendel and Beardmore of London, and carried out under the superintendence of Mr Leslie of Edinburgh, the Company's engineer. The capital expended in these works amounts to L.410,000, while it is understood that a sum of L.20,000 or L.30,000 more will be required for their completion.

In all places such as the above, where there is a deficiency of level to carry the water naturally to the highest parts of the town, there is no resource but in the employment of machinery. Steam power is most commonly applied to this purpose, and the water is generally either forced into a reservoir of sufficient height to supply the houses therefrom by natural gravitation, as in the city of York; or, it may be forced over upright pipes called stand-pipes, as is the practice in some of the water-works which supply London; or it may be propelled to the houses through a train of street-pipes, as is partially the practice in Glasgow. Aqueduct.

Aqueduct bridges or canals.

But though the system of pipes has thus superseded the use of stone channels all raised to a level in the conveyance of water, there are still cases, such as those of canals, where the water must be kept on a perfect level, and where, therefore, aqueduct bridges are still necessary in conveying it over the valleys; and of these we have long had examples in France, on the Languedoc canal. The first aqueduct bridges for canals in this country were those made by the Duke of Bridgewater, under the direction of the celebrated Brindley, and which, being quite new here, excited no small degree of astonishment. The first and largest was the aqueduct at Barton Bridge for conveying the canal across the Irwell, 39 feet above the surface of the water. It consisted of three arches, the middle one 63 feet span, and admitting under it the largest barges navigating the Irwell with sails set. It was commenced in September 1760; and in July of the following year the spectacle was first presented in this country, of vessels floating and sailing across the course of the river, while others in the river itself were passing under them. Since that period canal aqueducts have become more common; and many excellent examples are to be found both in England and Scotland. Of these are the aqueducts over the river Lune, on the Lancaster canal, designed by Rennie. a very excellent and splendid work of five arches, each 72 feet span, and rising 65 feet above the level of the river; and the Kelvin aqueduct, near Glasgow, which conveys the Forth and Clyde canal over the valley of Kelvin, consisting of four arches, each 70 feet span, and rising 70 feet above the level of the river. In Plate XLV., we have given views of three other principal aqueducts, viz., the aqueducts of Pont-y-Cysyllte, of Chirk, and of Slateford near Edinburgh. Of these the Pont-y-Cysyllte by Mr Telford is justly celebrated for its magnitude, for the simplicity of the design, and the skilful disposition of the parts, combining lightness with strength in a degree seldom attempted. This aqueduct serves to convey the waters of the Ellesmere canal across the Dee and the vale of Llangollen, which it traverses. The channel for the water is made of cast iron, supported on cast-iron ribs or arches, and these resting on pillars of stone. The iron being much lighter than stone arches, this is one reason why the pillars have been reduced apparently to such slender dimensions. They are quite strong enough, however, as experience has proved. The whole length of the aqueduct is about 1000 feet, and consists of 19 arches, each 45 feet span. The breadth of the pillars at the top is 8 feet, and the height of the four middle ones is 115 feet to the springing. The pillars have a slight taper, the breadth of the middle ones at the base being 15 feet. The height from the surface of the water in the Dee to that in the canal was to be 126 feet eight inches. The channel for the water consists of cast-iron plates, cast with flanches, and these screwed together with bolts; they are represented in the drawing, between the arched ribs and the railing. The lines there show the joinings of the different plates. In order to preserve as much water-way as possible, the channel is made the full width of the canal and towing-path, and the latter projected over one side, and supported inside by posts resting on the bottom of the canal. The aqueduct of Chirk was designed by the same able engineer, and serves also to convey across a valley the waters of the same canal. This aqueduct was the first in which any iron was employed. Hitherto the channel for the waters had been constructed of stone, or partly of stone and partly of clay puddle, which it was generally found very difficult to

keep water-tight for a length of time. It was determined, therefore, by Mr Telford, to try the effect of cast iron, and to lay it at first only on the bottom. The plates were accordingly laid directly over the sprandril walls, which they served to bind together, and united by flanches and screws. The sides of the channel were built with stone facings and brick hearting laid in water-lime mortar. This plan has succeeded completely, and the quantity of masonry in the aqueduct was thereby greatly reduced. The aqueduct itself is 600 feet long, and 65 feet high above the river, consisting of ten arches, each 42 feet span. The piers are ten feet thick.

The aqueduct of Slateford conveys the waters of the Edinburgh and Glasgow Union Canal across the valley of the Water of Leith at Slateford. It is an elegant structure, similar in plan to that of Chirk, only that the water-channel is composed entirely of cast iron, which is moreover built in with masonry. It is about 500 feet in length, and consists of eight arches, each 45 feet span; and the height of the canal is about 70 feet above the level of the river. On this canal another aqueduct of the very same construction occurs in crossing the valley of the Almond, and having several more arches. There are, in different parts of the country, various other aqueducts, which might be described, did our limits permit. It is the less necessary, as, excepting the formation of the water-way, these structures differ in no respect from bridges, particularly those undertaken not so much with the view of crossing rivers as of raising the level of the road entirely out of the valley,—an object now become of great importance, from the improvements within the last half-century in our modes of conveyance. Formerly people were content to traverse slowly all the inequalities of the country through which the road might pass, descending into the valleys, and mounting the steepest acclivities. Now, however, a road is thought imperfect, and quite behind the standard of improvement, unless every rise greater than 1 in 15 or 1 in 20 feet be cut down. In crossing the valleys, therefore, it is not enough now that we build a bridge in all respect sufficient for crossing the stream itself; we must raise it nearly to a level with the ground on each side of the valley; and this gives rise to new and very extensive works of this kind. Of these we may just instance the splendid bridge of one arch of 140 feet span, built over the Den Burn at Aberdeen, to form a new access into that town; also the beautiful bridge of Cartland Craigs, built by Mr Telford, over the little stream of the Mouse, on the new road from Glasgow to Carlisle, consisting of three arches 50 feet span, and elevated 130 feet above the bed of the stream. More recently the introduction of railways has opened a new and still wider field for the skill and talents of the engineer in the erection of such works. This species of road, it is well known, must be kept still more nearly on a level than any of the roads of the ordinary construction. (See RAILWAY.) In this respect the railway is somewhat similar to the old Roman aqueducts, and, where the country is low, must in like manner be elevated on a series of arcades. These bridges have received the name of *Viaducts;* there is an extensive one on the Liverpool and Manchester railway, termed the Sankey Viaduct, of nine arches; and numerous others have since been constructed throughout the country. But for the principles and mode of construction of these works, as well as of the aqueduct bridges, so far as the arch is concerned, we refer to the articles ARCH and BRIDGE; and for further information on the subject of aqueducts, see Julius Frontinus, *De Aquæductibus Urbis Romæ;* Raphaelis Fabretti *De Aquis et Aquæductibus Veteris Romæ Dissertatio;* Famiani Nardini *Roma Vetus*, lib. viii. cap. iv.; Plinii *Hist. Nat.* lib. xxxvi. cap. xv.; Montfaucon, *Antiquité Expliquée*, tome iv. tab. 128; Governor Pownall's *Notes and Description of Antiquities in the Provincia Romana of Gaul;* Belidor's *Architecture Hydraulique*, containing a drawing of the aqueduct of Maintenon; also *Mém. Acad. Par.;* Andreossy, *Voyage à l'Embouchure de la Mer Noire, ou Essai sur le Bosphore; Philosophical Transactions Abridged*, vol. i.; and Link's *Travels in Portugal.* (G. B.)

AQUILA. See ASTRONOMY.

AQUILA (Ἀκύλας), a native of Pontus, who flourished about A.D. 130, celebrated for his translation of the Hebrew Scriptures into Greek. His history is involved in much obscurity; but, according to the account of Epiphanius (*De Pond. et Mens*, c. 15), he was a kinsman of the Emperor Hadrian, who employed him in rebuilding Jerusalem (Ælia Capitolina). He was converted to Christianity, but on being reproved for practising the pagan astrology, he apostatized to Judaism. His version was very literal, and was used in place of the Septuagint in the synagogues. (*Novell.* 146.) Though the Christians generally disliked it, Jerome and Origen sometimes speak in its praise. The second edition was named κατ' ἀκρίβειαν, for its literal accuracy. The few fragments that remain are published in the *Hexapla* of Origen, and in Dathe's *Opuscula*, Lips. 1746.

AQUILA, a fortified city of the kingdom of Naples, and chief of the province Abruzzo Ulteriore Seconda. It is situated on the Aterno, in the vale of Aquila and Pescara, and is well built. Exclusive of the cathedral, it has no fewer than 24 churches, besides numerous monastic houses, while the population does not exceed 12,000 persons. It was founded in 1240, and soon became a very flourishing city; but war, pestilence, and especially the earthquakes of 1688, 1703, and 1706, have conspired to reduce it to its present state. The manufactures are linen and wax, with a considerable trade in saffron grown in the vicinity. It has a royal college, schools, hospitals, and a handsome theatre.

AQUILA, the principal standard of a Roman legion. The standard of Romulus is said to have consisted of a handful of hay, straw, or fern, affixed to a pole or spear; whence the company of soldiers who served under it was called *Manipulus.* This primitive standard was soon superseded by the figures of animals, which, as Pliny tells us (*H. N.* x. 4), were the eagle, wolf, minotaur, horse, and boar: but in B.C. 104 the eagle was permanently adopted. It was made of silver or bronze, and was represented with expanded wings.

AQUILEIA, an ancient Italian city, stormed and destroyed by Attila A.D. 452. It was recovered by Narses from the Huns, but it never regained its pristine grandeur. Before that period this Roman colony was 12 miles in circumference, and was a place of great wealth and magnificence. It was among the oldest bishop's sees in Italy, and in the sixth century its bishops had long contests with Rome. The Venetians, in 1420, conquered the adjacent country; and now Aquileia, with Udine and Friuli, forms a part of the Austrian circle of Goritza.

AQUINAS, or D'AQUINO, THOMAS, commonly called St Thomas, the greatest philosopher and theologian of the middle ages, was of noble descent, and nearly allied to several of the royal houses of Europe. He was born, according to the most probable opinion, in the year 1227, at Rocca Sicca, the castle of his father Landulf, Count of Aquino. Having received his elementary education at the monastery of Monte Cassino, he studied for six years at the university of Naples. The rising order of St Dominic numbered at that time many men of eminent energy and talents, zealous for the extension of their brotherhood, and particularly eager to draw into their ranks whatever of youthful genius and enthusiasm came within the range of their influence. The young Aquinas was soon led to choose a profession so congenial to his nature; and in direct opposition to the wishes of his family, embraced at the age of 17 the habit of St Dominic. His mother attempted in vain to rescue her son from the hands of the Dominicans, who first removed him to Rome and then attempted to convey him to Paris. His two brothers, officers in the

Tuscan army, were directed to intercept the passage of the travellers, who had proceeded no farther than Acquapendente, when the young friar was suddenly seized while reposing by a wayside fountain, and carried back to Rocca Sicca. Here he was kept for two years in close confinement, while his relatives exhausted in vain every argument and temptation which could have moved a less resolute spirit from its steadfastness. He employed his solitude profitably in meditation and study, having procured through his sisters a Bible, the Logic of Aristotle, and the Sentences of Lombard. Having at length succeeded in making his escape, he at once joined the Dominicans at Naples, and was soon after sent to study under Albert the Great, at Cologne. Here his taciturn and meditative deportment excited the contempt of his more loquacious fellow-students, who bestowed on him the title of *the Dumb Ox of Sicily*. His great teacher discerning better the profound genius of his silent pupil, told them that "When the dumb ox began to bellow, he would fill the world with the sound of his voice."

In 1245, Aquinas followed his master to Paris, returning with him at the end of three years to Cologne. In 1253 he again went to Paris, to fulfil the customary term of three years for obtaining his degree as doctor of theology. His lectures during that time were attended by crowds of enthusiastic scholars. The reception of his degree was obstructed by the contest of his order with the University of Paris, headed by William of St Amour. Both parties were summoned to plead their cause at Rome. Aquinas appeared as the champion of the mendicant orders, and the result of his powerful pleading was the condemnation of his adversary. In October 1257, he received his degree on the same day with his saintly friend Bonaventura.

For three years longer he continued at Paris, assiduous in teaching, preaching, and writing, His relative Louis IX. invited him frequently to the court, and sought his counsel on state affairs. The story of his one day startling the company at the royal table by exclaiming, out of an absorbing fit of meditation, "*Conclusum est contra Manichæos!*" is perhaps more generally familiar than his pointed reply to Pope Innocent IV. Aquinas found the Holy Father seated by a table covered with piles of indulgence-money. "You see," said the Pontiff, "the church is no longer in the days when she could say, 'Silver and gold have I none.'" "True, Holy Father," said Aquinas, "and she is therefore as little able to say to the sick of the palsy '*Rise up and walk.*'"

In 1261 Aquinas was summoned to Rome by Urban IV., and for several years lectured there and in the principal cities of Italy. In 1263 he attended the Dominican chapter held in London. Two years after he declined the offer made to him by Clement IV. of the archbishopric of Naples, as well as the more congenial office of Abbot of Monte Cassino. In 1269 he again visited Paris; and in 1272 was recalled to Naples. In January 1274 he was summoned by Pope Gregory X. to attend the council convoked at Lyons to settle the differences between the Greek and Latin churches. Though suffering from illness, he at once set out on the journey. Finding his strength failing on the way, he was carried to the Cistercian monastery of Fossa Nuova, in the diocese of Terracina, quoting, as he entered the cloister, the words of the psalm "Hæc requies mea in sæcula sæculorum!" After lingering for some weeks, he expired on the 7th of March 1274. About a century after, his body, for the possession of which many cities had eagerly contested, was removed to Toulouse, and buried with much pomp in the Dominican Church.

The highest honours which the church could bestow were awarded to the memory of Aquinas. *The Angelic and Universal Doctor, the Angel of the Schools, and the Eagle of Theologians,* were among the admiring titles conferred on the greatest of the schoolmen. He was canonized in 1323 by Pope John XXII.; and in 1567 Pius V. ranked the festival of St Thomas with those of the four great Latin doctors, Ambrose, Augustine, Jerome, and Gregory. Still higher is the honour implied in the fact that the repeated testimony of the church has stamped the authority of Aquinas with a kind of minor infallibility.

Any just estimate of his character and works would involve a view of the whole scholastic system, which attained in him its highest and most comprehensive development. The most philosophical of all the schoolmen, as his master Albert was the most learned, he consummated the harmony of the Aristotelic philosophy with the doctrines of the church; and to him mainly was due their all but exclusive empire till the era of the Reformation. With reference solely to his ethical system, Sir James Mackintosh (*Prelim. Diss.*, p. 328) speaks of Aquinas as "the moral master of Christendom for three centuries." Those, indeed, who are accustomed to regard the scholastic philosophy indiscriminately as a system of mere laborious trifling, may find some scope for ridicule in the endless divisions and subtle questions of the Angelic Doctor on the nature and properties of angels and other impractical themes; but if the unvarying dialectical force and the occasional profound suggestiveness arouse no sympathy with the mediæval admiration of "friar Thomas and his goodly lore," it is to be feared that the fault is not wholly with the writer. The mental fecundity which in so brief and interrupted a lifetime produced a mass of writings so voluminous, is in itself wonderful, but more remarkable is the power of continuous thinking which left its impress upon them all. The striking harmony of thought between Aquinas and Augustine, suggested the fanciful conception that the soul of the African bishop had reappeared after seven centuries in the body of the Italian monk. In him was again seen the union of the highest philosophical power with the most simple and fervent piety, the vigour and acuteness of a master-intellect, with the unearthly humility and devotion of the saint.

The best edition of the works of Aquinas (Rome, 1570–71) is in 17 vols. (18 tom.) folio. These consist of commentaries on Aristotle; commentaries on the Scriptures; the *Summa Theologiæ*, his greatest work, and the most complete and extensive body of theological and moral science ever attempted; his *Summa adversus Gentiles;* and miscellaneous pieces (*Opuscula*). They include also several Latin hymns.

The followers of Aquinas were called *Thomists*. Their fruitless contentions with the *Scotists* or disciples of the great Franciscan Duns Scotus, long divided the schools.

AQUINO, the ancient *Aquinum*, a town and bishop's see of Naples, in Terra di Lavoro. It was one of the chief cities of the Volsci, but has now only 1100 inhabitants. It contains numerous Roman remains, including an amphitheatre and a triumphal arch. Here Juvenal was born; and, according to some, Thomas Aquinas.

AQUINO, *Carlo d'*, an Italian writer, born at Naples in 1654. He was long professor of rhetoric at Rome. His principal works are poems and dictionaries. He translated Dante into Latin verse, but his version has little merit. He died at Rome in 1737.

AQUITANIA, one of Cæsar's great divisions of Gaul. It was not subdued until the reign of Augustus, who extended its limits to the Loire and Cevennes range. In the reign of Honorius it was conquered by the Visigoths, from whom it was wrested by Clovis. Thenceforth it was considered as part of France, until it fell by marriage into the hands of Henry II. of England. It was an apanage of the English monarchs, until Charles VII. finally united it to the French crown, by the capture of Bordeaux in 1452.

ARABESQUE, *Grotesque*, and *Moresque*, are terms applied to paintings and ornaments which consist wholly of foliage, plants, stalks, &c.—the Moors, Arabs, and other Mahometans being forbidden by their religion from making any images or figures of men or animals

ARABIA.

Arabia.

This extensive country, which is situated at the south-western extremity of Asia, has been famed in all ages for freedom and independence; for the peculiar character and manners of its rude tribes; and for the wild and cheerless aspect of its interior deserts, contrasted with the fertility of other tracts, the products of which have always formed the staple articles of the Arabian trade. It has been distinguished in history as the scene of great events, and especially of that wonderful revolution in religion, under the influence of which the Arabs, inflamed with the spirit of proselytism and of conquest, spread their victorious arms over the fairest portions of the earth, and brought about not merely the downfall of empires, but a revolution of opinion and manners which gradually extended over the greater portion of Africa, and over the eastern world from Constantinople to the frontiers of China.

Arabia is a peninsula, stretching north-west and south-east. It has the form of an irregular lozenge, and is inclosed on three sides by the ocean. It is bounded on the south-west and west by the Red Sea and the Isthmus of Suez; on the north-east by the Persian Gulf and the lower course of the Euphrates; on the north-west by Syria, the Euphrates, and the intervening desert; and on the south-east by the Indian Ocean. Its length from this ocean to the frontiers of Syria is about 1400 miles, and its breadth from the Isthmus of Suez to Bassora about 900. The peninsula enlarges in breadth as it approaches the Indian Ocean, and it is greatest in the parallel of Djiddah, viz., about 2250 miles. The division of this country by the ancients was, according to the natural qualities of the soil, into Arabia Petræa, Arabia Deserta, and Arabia Felix. No very distinct boundary was assigned to these divisions. Under Arabia Petræa was included that barren and rocky tract in the north-west of Arabia which is situated between the northern shores of the Red Sea and the Mediterranean, and which may have extended southwards nearly to Mecca. Arabia Deserta was separated from Mesopotamia on the north by the Euphrates; on the west it was bounded by Syria, Judæa, and Arabia Petræa; on the east and south it was separated from Chaldea and Arabia Felix by deserts and mountains. Arabia Felix was bounded on the north by Arabia Petræa and Arabia Deserta, on the south by the Indian Ocean, and on the east and west by the Persian Gulf and the Red Sea. The modern division of the country is entirely different.

Divisions.

The eastern geographers do not agree as to the great divisions of the peninsula and the limits of these divisions. Some speak of two divisions only, namely, Hedjaz and Yemen, but it is self-evident that they do not mean thus to divide the whole of Arabia, but only the western portion of it, or the coast along the Red Sea. Abulfeda mentions five provinces, Tehama, Nedjed, Hedjaz, Yemen, and Arudh or Ared, but this division too is incomplete. The opinion of the Baron von Hammer, who collected and compared a vast amount of geographical evidence from oriental sources, warrants the following as the true great divisions of Arabia. 1. In the north-west *El Hadjr*, literally the "Stony," or Arabia Petræa, with natural boundaries to the east. 2. South of it, *El Hedjaz* along the Red Sea, as far down as about N. Lat. 19°, with natural boundaries, viz., in the east, the table-land of El Nedjed, and in the south, the Tehama of Assyr, that remarkable gap in the great western mountain chain. 3. *El Yemen*, the southern portion of the coast along the Red Sea, extending eastward over a portion of the table-land of southern Nedjed and the low tract El Jof. 4. *El Nedjed*, the upland or high plateau, being the central portion of the peninsula; the tracts bordering on Hedjaz and Yemen are called El Nedjed El Hedjaz, and El Nedjed El Yemen. It is bordered in the south by the great desert *El Ahkaf*. 5. *Hadhramaut*, along the Indian Sea, between Yemen, El Ahkaf and Es Shehr. 6. *Es Shehr*, also called Mahra, because it is inhabited by the tribe Mahra, a dreary tract east of Hadhramaut, which is said to have been changed from a fertile country into a wilderness by the curse of Nebbi Hud, the ante-Mahometan prophet of this part of Arabia. It contains, nevertheless, some well-cultivated and well-inhabited districts. The language of the inhabitants differs very much from the modern Arabic. 7. *El Oman*, the north-eastern projection of South Arabia, at the entrance of the Persian Gulf, and bordering in the south-west on El Ahkaf. 8. *El Hedjer*, or El Bahrein, the coast along the Persian Gulf as far north as the head of the gulf, and bordering in the west on the high plateaux of the interior. It is as frequently, but erroneously, called *Lahsa* or *El Ahsa*, this being the name of a comparatively small district. 9. *El Yemamah*, seems to be the south-eastern portion of El Nedjed. It borders on Hedjer, Oman, and the desert El Ahkaf.

Besides these great divisions, there are others which deserve a short explanation, as they frequently occur in works on Arabia. First among them is *Tehama*. The name designates the narrow belts of sandy lowland between the mountains and the sea; and the whole coast of the Red Sea being of that description, and called accordingly, a belief has sprung up as if the name referred only to that tract. But as there is a Tehama of Hedjaz, so there is one of Yemen, which, however, comprehends some hilly districts; in short, every province bordering on the sea, has its great Tehama; and every district on the coast, or even sea town, has its smaller local Tehama. *El Jof* is the name of a large district to the east of Arabia Petræa, of another one to the east of Yemen towards Hadhramaut, and of several other inland plains; for it is a name in physical geography, meaning a level inland tract lower than the high plateaux, but still higher than the low lands. El Ahkaf signifies a desert characterized by low winding sand-hills, and besides the great El Ahkaf, there are several, and perhaps many, smaller deserts which are distinguished by that name. The great desert between Syria and the head of the Persian Gulf is called Badieh el Arab.

The desert tracts occupy a vast proportion of the soil of Arabia. They consist either of bare rocks, or of hard, loose sand, and are almost destitute of fresh water. Whole years frequently pass away without rain, and the burning sands, reflecting the solar rays, occasion such intense heat as is not felt even in countries that lie directly under the equator. There are no rivers, the mountain torrents being speedily imbibed by the sandy soil; and the scanty supplies afforded by deep wells and springs, scattered at distant intervals, are the sole dependence of the fainting traveller for refreshment, and frequently for life. The aspect of desolation is sometimes relieved by verdant spots, which appear like islands in the trackless ocean; and some rare and hardy plants, such as the tamarind and the acacia, which strike their roots into the clefts of the rocks, find here a congenial soil, and flourish amid the surrounding waste.

Climate. Hot winds.

In the Arabian plains the thermometer is generally above 100° during the night, at 108° in the morning, and in the coolest and shadiest parts in the course of the day it rises to 110°, and sometimes higher. All travellers who have

Arabia. visited the coasts of the Red Sea appear to have been oppressed by the extraordinary heat, and to have considered the temperature of other tropical countries as moderate in comparison. The sultriness of the nights is another peculiar evil of the Arabian climate, and a predisposing cause of disease. For this peculiarity the country is partly indebted to its position, hemmed in between the continents of Asia and Africa, and effectually protected by the latter from the influence of the south-west monsoon, which blows during the summer on the coasts of India, and ushers in the periodical rains: Arabia never experiences the refreshing influence of this wind. It seems to blow exactly along its south-eastern shore, on which prevail baffling winds, or a dead calm.[1] During the whole summer the heat in the lower plains on the coast is so steady and equable that the atmosphere remains in a state of repose. No change of temperature takes place to set the winds in motion; and dead calms occur, and sometimes continue for sixty days without interruption. When the temperature begins to vary with the change of the seasons, and the winds resume their activity, the country is visited by the *simoom* or the hot blast from the deserts, under whose withering influence all nature seems to languish and expire, and which has the quality of extracting from whatever it touches every trace of moisture, and to produce, when it is inhaled by men or animals, a painful feeling, as of suffocation. But though its effects are pernicious to health, they have been greatly exaggerated by credulous or ill-informed travellers; and among others Niebuhr, to whom we are indebted for much valuable information respecting Arabia, ascribes to it the power of suffocating any living creature that is exposed to its influence. Others imagine that it has poisonous qualities. It appears, however, from the accounts of various travellers, and among others of Mr Buckingham, that its effects are produced solely by heat. When it is suddenly inhaled, it may, in the same manner as a hot blast from an oven, cause faintness or sickness, and even swooning; but this feeling is occasioned wholly by the heat and parching qualities which it contracts in its passage across the burning sands. The desert consists in many parts of loose sand, interspersed with sharp and naked rocks; and the effect of these violent winds is to raise up in clouds this fine sand, and to set it afloat in the atmosphere in such quantities that it is impossible to see to the distance of a few yards. On such occasions, during the violence of these sand storms, it is the instinctive practice of camels and other animals to lie down, and bury their nostrils under the sand, to avoid the influence of the wind. In this situation the traveller generally lies down on the lee side of the camel, and in a short time the sand is blown up to the level of the animal, which has accordingly to rise and to lie down on a new foundation, in order to avoid being entirely covered. But in many cases, from weariness, faintness, or sleepiness, occasioned by the great heat, and often from a feeling of despair, both the man and the animal remain on the ground, and in twenty minutes they are buried under a load of sand, and perish miserably in those inhospitable deserts. The approach of the simoom wind is indicated by an unusual redness in the sky, which during the prevalence of the wind seems to be all on fire.

But though a large proportion of Arabia consists of arid and burning deserts, the country immediately behind the dry and sandy plains, which stretches backwards from the seashore, rises into rocky and precipitous hills, with intervening valleys of remarkable fertility. Those mountainous tracts, which send forth ridges into the interior in various directions, enjoy a temperate climate; ice and snow are known at Tayef and Sana, and the Baron von Wrede relates, that on the high plateaux of Hadhramaut the frost is sometimes so intense that the people use axes for breaking up the ice on their reservoirs. All these interior and highland districts are occasionally refreshed by copious rains, though they do not lie within the range of the monsoons, which in the peninsula of Hindustan usher in the rainy season. Those rains occur at different times of the year, according to the position of the mountains. On the western declivity of the mountains of Yemen, along the shore of the Red Sea, they commence in June and terminate in September, which is the season of the monsoons in India. This tract is also refreshed by a spring rain, while on the eastern declivity of the same mountains the season of the rains is between the middle of November and the middle of February. In Hadhramaut and Oman, along the shores of the Indian Ocean and the Persian Gulf, the rainy season lasts from the middle of February to the middle of April; in the highlands of Hadhramaut, transient but frequent thunderstorms, with torrents of rain, mark the months from April to September. The prevailing wind in summer is from the west. The simoom, by which name the Arabs distinguish every hot wind, comes from the east; the south is reckoned favourable to vegetation; while the influence of the north wind, whether it be hot or cold, is always thought to be pernicious to the health both of man and beast. It is occasionally so sultry that it heats metals in the shade as if they were exposed to the sun. On the Persian Gulf the south-east wind is common, and is accompanied with moisture, which, when the heat is intense, occasions violent sweatings, and is even more injurious to health than the hot and dry blast from the northern desert. No traveller has given any accurate measurement of the height of the Arabian mountains; but the decided change of climate which takes place in these upland regions marks a considerable elevation above the adjacent plains.

Soil. Among the Arabian highlands great diversities of soil prevail; and the craggy precipitous form of the hills is unfavourable to fertility. They afford neither sufficient space nor soil for vegetable productions, and the earth is continually washed away by the torrents. In many parts the rocks are basaltic in their form, and so steep that the road ascends by regular steps cut in the rock. These mountainous tracts are in general well cultivated and productive, especially the southern and mountainous provinces of Yemen and Hadhramaut. This was the celebrated region of Arabia Felix, which, contrasted with the adjacent deserts, might deserve that appellation, being a fertile country, yielding the far-famed productions of balm and frankincense, and many sweet-scented trees and shrubs, of which the delicious fragrance, according to the descriptions of poets, was wafted by the winds over the surrounding seas. The mountains of Hedjaz and Yemen, which run along the eastern shore of the Red Sea, are precipitous and often rocky; but water abounds in wells, springs, and rivulets. This entire tract of country is well peopled as far as the mountains which overlook the Indian Ocean, and contains numerous villages of the Arab tribes. In all parts where water is near, and can be artificially spread over the ground, trees and inclosed fields are found; and among the rugged and basaltic mountains extensive and well-watered valleys, which to the south and the east are covered with the herds and flocks of the Bedouin Arabs, and to the north and west, towards the Red Sea, with industrious cultivators, who have relinquished their

[1] It is mentioned by Fraser, in the account which he gives of a *Voyage from Bombay to Mascat*, in the Persian Gulf, that the moment they doubled Cape Rassel Gate, a corruption of Ras-el-Hadd (*ras* means *cape*), and entered the Persian Gulf under the lee of the Arabian land, they were forsaken by the south-west monsoon, and encountered baffling winds or calms until they arrived at Mascat, which is about 120 miles up the Gulf.

vagrant habits, and live in houses. In these valleys, which are frequently separated by intervals of barren rock, and the passes or entrances into which, through the mountains, are so narrow that they scarcely allow two camels to walk abreast, the villages are embellished with gardens, palm-groves, and date-trees, the fruit of which forms in many districts the staple article of the agriculturist; and with extensive plantations of coffee, which, when in flower, exhale an exquisite perfume. In many parts of Yemen whole mountains of basaltic columns are seen, which are rendered subservient to many useful purposes. Being easily separated, and formed into steps, they facilitate the ascent of the heights where it is difficult; and they supply materials for walls to support the plantations of coffee-trees on the steep declivities of the mountains.

The country between the mountains of the Hedjaz and the Red Sea is part of that narrow belt of sand which encircles Arabia. It is called Tehama, the appellation given to all the low plains on the coast, which are generally barren, having fewer fertile spots and more scanty pasturage than the mountains, where rain is more common. Of the regions which are washed by the Indian Ocean and the Persian Gulf we have no full or accurate information. We know, however, that they are skirted by sandy plains similar to those on the western shore. The country which overlooks the Persian Gulf at Mascat has an extremely desolate appearance, consisting merely of sands, and naked rocks blackened by the scorching rays of the sun. It rises into mountains, which may be seen from the sea, and probably attain an elevation of from 1500 to 2000 feet.

Of the provinces of Hadhramaut, Shehr or Mahra, and Oman, more will be said afterwards.

The large province of El Hassa or Bahrein extends along the curve of the Persian Gulf, being in its narrowest part not above 60 miles broad. The coast is a level Tehama, but ridges of hills intersect the interior; and towards Nedjed in the north, and Yemamah in the south, rise the high ranges of Djebel Ared and Djebel Athal, forming the eastern edge of the great table-land of central Arabia. Bahrein is distinguished by its abundance of fresh water, which, although often prevented by the fierce rays of the sun from collecting on the surface, and forming permanent streams, is yet easily to be obtained, even in sandy plains, by digging to the depth of a few feet. Wells are consequently numerous, and enable the natives to cultivate clover, with which they rear a breed of excellent horses. There are many lakes. It appears that here, still more than in any other part of Arabia, the water of the rivers and torrents, flowing down from the higher parts towards the sea, is not entirely absorbed by the sand, but continues its course underneath it, on a substratum of marly clay, the undulations of which it follows according to the pressure it receives from the higher level, giving rise to large bodies of subterranean water. Thence, also, the phenomenon observed along the coast of this tract, of powerful springs of fresh water bursting forth from the bottom of the sea, and easily accessible when the tide is low. At high tides they are sometimes covered with twelve feet of sea water, but so great is their volume and power, that the water remains quite sweet at several feet from the bottom; and, as Captain Skeine relates, divers provided with skin bags will plunge into the salt sea to fetch a supply of fresh water. The fact of powerful salt springs rushing up from the bed of fresh-water rivers, as, for instance, near Kreuznach on the Nahe, in Rhenish Prussia, stands in striking and convincing contradistinction with these fresh-water springs in the Sea of Bahrein. Nor is this phenomenon only of local importance, as is the case with the fresh-water springs at the Giant's Causeway, in Ireland; it bears on, and helps to solve, one of the most important questions relating to the physical geography of Arabia. We allude to the positive statement of Edrisi and other Arabic geographers, that a large river, El Aftan, originating in the interior, traverses the coast, and flows into the Gulf of Bahrein. Yet, when Captain Sadleir crossed and recrossed the supposed line of the Aftan, on his expedition to the camp of Ibrahim Pasha, in 1819, he found no traces of any considerable river; and as the existence of the El Aftan had already been previously denied as being too improbable, it was now set down as a fable altogether. But even suppose he did cross that line, which is by no means certain, although he penetrated as far as Es Sabeh, a village to the south of El Hofhuf, the existence of so much subterranean water, which is of easy access, according to the Captain's own statement—the numerous wells, pools, and even lakes—and last, but not least, the submarine springs of fresh water along the coast, principally about the locality where the Aftan might be supposed to reach the sea,—all these circumstances make it extremely probable that the lower part of the Aftan having been overwhelmed and buried by the sand, the water nevertheless continued to press on upon the clayey substratum, and spreading about in various directions, at last reaches the sea at a level considerably below its surface; when, bursting through the light and sandy bottom, it produces those singular phenomena on the coast of Bahrein. Wellsted entertained such views when he visited the country. There are many other facts bearing upon the existence of a large river in Central Arabia, of which more will be said in the description of Assyr.

The coast of El Bahrein is indicated by a large gulf bearing the same name, extending 80 miles inland, at the mouth of which lies the large island of Bahrein, which is known for the productive pearl fisheries carried on in the gulf. It is a pleasant, well-cultivated island, though once a den of pirates; its capital, Awal or Bahrein, has 5000 inhabitants. On the opposite coast lies the seaport El Katif, with 6000 inhabitants; and in the interior, at a very short distance from each other, are Mubarruz and Hofhuf, said to be peopled, the former by 30,000, and the latter by 40,000 souls, which may have been correct at the time when the Wahabys were powerful in these parts. Quite in the north, not far from the embouchures of the Shat-el-Arab, the united Tigris and Euphrates, lies the small seaport El Kueit or Grane.

Mountains of Arabia.

It has already been observed that, with the exception of Arabia Petræa, the whole northern part of the peninsula is a comparatively low plain, intersected by ridges of hills of little elevation. It extends south as far as north latitude 28°. There the Djebel Shammar rises abruptly, a lofty range traversing the interior in a direction from west to east, and visible at a great distance. The Arabs say that its central portion, or Djebel Shammar, properly speaking is as high as Mount Lebanon, or about 9000 feet. The great hadj and caravan roads from Damascus and Baghdad to the holy cities and the inland of Nedjed traverse this vast and arid district, but our knowledge of it is still very imperfect. Dr Wallin, professor in the university of Helsingfors, in Finnland, explored the tract a few years ago, starting from the Gulf of Akaba, and thence proceeding to the foot of Djebel Shammar, whence he returned by the road to the Tigris. He was the first known European who ever proceeded so far in that direction, but his account in the Journal of the Royal Geographical Society of London, is of more importance to the linguist and antiquarian than the geographer. Along the Derb Bereidha, or hadj road from Baghdad, there are numerous deep and very carefully constructed wells, among which that of Wakiyeh, which was built by order of Melek Shah, Sultan of the Seldjuks in Persia, is said to be 800 feet deep by 10 wide. Several wells have been constructed by Sobeidah, the wife of the great Khalif Harun-al-Rashid.

The entire extent of Arabia south of Djebel Shammar is an elevated table-land, resembling a barren rocky crust raised by subterranean power. Ridges of varying elevation rise above it in a direction from west to east, and it is rent asunder in all parts by deep gaps forming narrow *wadis* or valleys flanked by bare, precipitous rocks. These are the only localities containing a settled population, being watered by temporary or permanent streams which render the soil fit for cultivation. Nearly all the towns are situated in such wadis, as far instance Derraiyeh, the once flourishing capital of the Wahabys. Large tracts, however, are considerably lower than the general level of the table-land, and being

Arabia.

covered with moveable sand, which has filled up the gaps by which the rocky substratum is cut up, form the most dangerous among all the deserts of Arabia. The great wilderness, and the smaller ones, called El Ahkaf, belong to this description. It appears that a broad but high plain or valley, beginning in the west at the foot of the mountains of Assyr and sloping down towards the Persian Gulf, bisects that immense table-land into a northern and a southern portion. This tract was never visited by Europeans, but eastern geographers inform us that it constitutes the best part of the great province of Yemamah: it is well watered and produces an abundance of corn and fruit. The eastern less frequented caravan road from Mecca to Baghdad crosses it in a direction from south-west to east and north, touching or passing near the village El Hauta, which, according to Burckhardt, is the birthplace of the famous Abd-el-Wahhab, the founder of the sect of the Wahabys. The principal mountain chain which overlooks the table-land is Djebel Imariyeh or El Ared. From the Alpine highlands near Tayef, it stretches north-east as far as Derraiyeh, falling off in the north like a stupendous wall of white rock, whence we may infer that it is of limestone formation. From that town it continues in a more northern direction almost parallel to, but still distant from, the Persian Gulf, and forming the natural boundaries between Nedjed and Hedjer or El Bahrein. From its central portion near Derraiyeh another chain runs north by west under the name of Djebel Tueik which seems to join the latitudinal chain of Es Shammar in its very centre, which, on account of its serrated appearance is commonly called El Djebel. Between the chains of Ared and Tueik lies the district of Sodaïr; west of Mount Tueik are the districts of Kasim and Woshem; and to the south-east of Derraiyeh is the smaller one of Khardj. The environs of Derraiyeh are full of once thriving towns, situated in narrow rocky wadis or glens, but since the last successful invasion of the Egyptians they are in ruins. To the south of Western Yemamah, and parallel with Djebel Imariyeh, but at a distance of 200 miles from it, a chain of high mountains has been observed in a north-east direction, which seems to be the Djebel Menakib of the Arab writers. There is reason to believe that there are many more inland chains, but we know nothing positive about them.

In proportion as the arid and elevated interior of Arabia approaches the sea, it begins to lose the peculiar features of a high table-land. Almost everywhere its descent towards the lower level presents several terraces, the serrated edges of which form as many chains of mountains. On approaching the peninsula from the seaside, it first seems as if there were but one such edge, but on surmounting the first, the traveller soon meets another, and in many localities a third and a fourth one; and although the ascent is not always steep, the increasing difference of temperature indicates a higher level. The lower edge of the table-land towards Hedjaz is commonly called Djebel-el-Hedjaz, of which the section between north latitude 25° and 23° bears the name of Djebel Raduah, and is about 6000 feet high. East of it lies the holy city of Medinah, on the third terrace, and consequently at a considerable elevation, and perhaps as high as from 4000 to 5000 feet above the sea. Between Mecca and Tayef, the chain bears the name of Djebel Kora, of which M. Gazuan is not only the highest portion, but probably the highest peak in Arabia, if it be true that its summit is covered with snow even in summer, which would give it an altitude of about 14,000 feet. But this is very questionable. It has already been observed that in north latitude 19°, a remarkable gap, the Temanah, or perhaps Tehama of Assyr, affords an easy communication between the coast and the interior, being, at the same time, the natural boundary between Hedjaz and Yemen. The extensive chain from that great defile down to the Straits of Babelmandeb is called Djebel-el-Yemen, and the southern portion simply El Djebel, on account of its many peaks and serrated aspect. It appears to reach an altitude of 9000 feet, and in the latitude of Sana, swells out into a broad mountainous tract sloping down abruptly towards the district El Jof, and the sandy plains of Mareb. The town of Sana, the capital of the dominions of the imam or sultan of Sana, to whom all Yemen is either directly or indirectly subject, lies 5000 feet above the sea, the surrounding peaks rising to from 2000 to 4000 feet above that high plain. Numerous torrents flowing in deep valleys between high precipitous rocks, water this interesting tract, but in the dry season they dwindle into streamlets. In the arid tehamas they dry up entirely, at least near the surface, because at the depth of a few feet below the burning sand, water is always obtainable by digging, except in years of total drought.

Irrigation.

In few parts of Arabia is the system of irrigation brought to such perfection as in the highlands of Yemen. Water is superabundant in the rainy season, but the rapid descent of the torrents causes it to vanish as fast as it fills the glens to overflowing; and in the dry season, the hot rarified air absorbs it in such a degree as to lay all water-courses dry. Deep wells and reservoirs, together with tanks and cisterns of every description, thus become a matter of necessity; and it is owing to the surprising care bestowed upon such works, that the coffee plantations are in so luxuriant a condition. As long as the lower reservoirs, which, however, are still higher than the respective terraces for the irrigation of which they are constructed, yield a supply, those on a higher level are not only spared, but still fed if possible; but in proportion as the former become exhausted, the latter are opened; and the water descending through covered conduits again fills those which are nearest to the plantations. On the drying up of these, also, the deep wells in the shady glens are resorted to, and the water is carried up the hills in skin bags on the backs of donkeys. The inhabitants themselves will lend their backs to this drudgery to save their crops. Around the stem of each coffee-tree, pebbles are heaped up, which serve the double end of preventing the roots from being laid bare by torrents, and of keeping the soil moist in the dry season.

Vegetable produce.

Arabia, from its diversified surface, contains within its bounds the climates and the vegetable produce of different countries. The mountainous tracts yield in great abundance wheat, barley, and an inferior species of grain called *durra*; also the fruits of Europe in equal variety and perfection, such as figs, apricots, peaches, apples, almonds, pomegranates, grapes of the very best quality, and excellent dates, which in many parts are the chief food of the inhabitants, as well as an article of export. Many of the fine fruits of India have been transported thither, and are now naturalized. Such are the banana tree, the mangoustan, the Indian palm, and the Indian fig-tree. Besides the European grains it yields abundantly rice and maize. In the highland provinces forests are sometimes seen, which contain many trees little known, or differing extremely from the same genera in northern countries. The tamarind-tree refreshes and embellishes the country by its agreeable shade and elegant form. The balm-tree is peculiar to Arabia, which is also the native country of the coffee-tree, though, according to the Arabians, it comes originally from Abyssinia. The balm-tree has not a beautiful appearance, and its qualities are not appreciated in the southern province of Yemen, where its wood is burnt for a perfume. In the Hedjaz the inhabitants collect the balsam and bring it to Mecca: it is thence exported to Turkey, where it is in high estimation. The tree from which incense distils is found in part of Hadhramaut, along the shores of the Indian Ocean. Arabia has been in all ages celebrated for sweet-scented shrubs and trees; and Burckhardt mentions, that one morning at sunrise, when he was on his road from Tayef to Mecca, every tree and shrub exhaled a delicious fragrance. There are various species of the sensitive plant, of which the splendid flowers, of a beautiful red, are formed into crowns for festive occasions. The sugar-cane and the indigo-shrub are found in different provinces; and the shrub from which senna is produced is cultivated in all that part of the country which lies opposite to Upper Egypt. The Arabians cultivate garden vegetables, such as lettuce, carrots,

Arabia.

radishes, water-cresses, and a great variety of gourds, cucumbers, pumpkins, and melons. The melon is in such variety and abundance that, for a part of the year, it constitutes an article of food. Many plants and herbs which have been brought from India are now naturalized in the country; and there is abundance of indigenous plants, noted for the beauty of their flowers and their fragrant smell. The gardens at Tayef, among the mountains, 72 miles east of Mecca, are renowned for roses of such exquisite beauty and fragrance, that they are sent to all parts of the country. The soil of the desert, though sandy, yields a variety of herbs, which constitute the food of cattle; and every district has a peculiar plant, which will grow in no other part. These herbs grow to the height of three, and some of them of six feet; and when they are withered by the sun they are eagerly devoured by the camel.[1]

Coffee-tree.

The celebrated coffee plantations of Yemen occupy the slopes of these valleys, rising in terraces one above the other, to a height of about 3000 feet above the sea, beyond which point the cultivation of the tree ceases to be profitable, or becomes impossible. A large proportion of the choice product, which is known in Europe under the name of Mokha coffee, because most of it is exported from Mokha, grows on those terraces; but as much is imported from the opposite coast of Africa, and, being exported again, is sold in Europe under the same name. The finest coffee is said to grow in El Ghamid, a small district in north latitude 20°. The inhabitants of Yemen, even the wealthier, seldom use the coffee-bean (*boon*), but only the *Keshir*, or the husk, in which it lies; the bean being sold at Mokha and Djidda for exportation. The beverage also, which is obtained from the roasted husks by an infusion of boiling water, goes by the name of Keshir, and coffee-houses or *Keshir eshes*, that is, *huts*, are everywhere to be found, even along the roadside, for the accommodation of travellers. Many of these establishments are pious institutions, where the wayfarer is gratuitously accommodated, for three days, with lodging, keshir, and durra. Another similar beverage is obtained from the fleshy part of the berry; and this is sometimes called *cawa*, whence our *coffee*. According to the universal statement of the natives, the coffee-tree was first brought over from Africa, and cultivated in Yemen, in the fourteenth century of our era, by a holy man named Shadeli, who is still revered by the Arabs as a benefactor of mankind, so much so that they never raise a cup of coffee, or keshir, to their lips without previously praising his name in a short prayer. Modern travellers have confirmed the fact, that the original home of the coffee-tree is in the high, mountainous country to the south of Abyssinia; but while some report that the district of Kaffa is not only its cradle, but has also lent its name to the tree, others, among whom that eminent investigator, Dr Beke, contend that no coffee grows in Kaffa. However this may be, the inland town of Hurrur, which lies to the east of Kaffa, is a chief market for African coffee.

Kaat is also extensively cultivated and consumed in Yemen. It is a small tree or shrub, the leaves of which resemble those of the willow, and, when dried, taste somewhat like tea. The Arabs chew it because it exhilarates the mind, keeps people awake, and makes them talkative, whence it is now in high estimation among so social and garrulous a nation as the Yemenites are. The taste of the young leaves is a delicious mixture of sweet and bitter, the former prevailing; so much so, that water drank after it tastes like scented lemonade. The rich use the young leaves with the morning dew still upon them, and this makes them dear, as they are gathered at some distance from the towns. Wealthy Yemenites will chew from two to three crowns' worth of Kaat in one day. Dr Beke brought some well-preserved sprigs with him from Abyssinia, where it also grows, which the writer of this was kindly allowed to examine and taste.

Animals.

The wild animals of Arabia, which are principally found in the mountains, are the panther, sometimes mistaken for the tiger, the ounce, the hyena, the wolf, the fox, a species of wild dog of a black colour, common in many countries in the East, the wild cat, the jackal, the wild ox, and monkeys in great numbers. In the sandy tracts is found that curiously constructed animal the jerboa. The wild boars are very numerous, but not in the heart of the desert. The Arabs who live at Tadmor in Northern Arabia are famous for their dexterity in killing them with the lance. The beautiful and timid gazelle is found all over the Arabian desert. On the eastern frontiers of Syria there are several places allotted for the hunting of these animals, which are taken by hundreds. There are several sorts of lizards, and the land-tortoise is common, being brought by the peasants in cart-loads to the markets of many towns in the East. The domestic animals are the horse, the ass, the camel, and the ox.

Horses.

The Arabian horse has been justly renowned in all ages of the world for all the finest qualities, namely, swiftness, patience of fatigue, spirit, and docility of temper; and it is from the Arabian breed that the European horses derive all their most valuable properties. The best horses are found in the greatest numbers in the luxuriant pastures of Mesopotamia, the banks of the Euphrates, and in the Syrian plains. In Nedjed the horses are also of a very fine quality, though they are not so numerous as in these countries; and they are still more scarce in the southern provinces of Yemen, Oman, and Hadhramaut, on the shores of the Indian Ocean, owing to the great heat of the climate; nor are the mountainous regions of the Hedjaz favourable to the rearing of this fine animal. There are not, according to Burckhardt, more than 6000 horses in the whole western country of Arabia, from the northern point of Akaba on the Red Sea to the southern coasts, comprising the great chain of mountains and the western plains. The provinces of Yemen, Hadhramaut, and Oman, are also supplied with horses from the pastures of Nedjed.

In the wars and inroads of the desert, the Arab soldier, whether he is pursuing, or flying for his life over the naked plain, wholly relies on the quality of his horse. On this account they spare no pains in rearing their horses and in preserving the purity of the breed. The birth of every noble foal is ascertained by the presence of eye-witnesses, and a written certificate is made out of its distinctive marks, with the names of its sire and dam, which is wrapt in a small piece of leather covered with wax-cloth, and is hung round the animal's neck as the standard and evidence of its value. The genealogical table never ascends to the granddam, because every Arab knows by tradition the purity of the whole breed; and there are many horses and mares of which the noble descent is of such notoriety throughout the tribes, that no written evidence of the fact is required. The Arabs reckon five noble breeds of horses, whose lineal descent they assert to be from the five favourite mares of the prophet. But as all the collateral branches claim the same illustrious ancestry, there is an infinite variety of noble breeds in the desert; and every mare which is particularly handsome, and belonging to any of the five chief races, may give rise to a new breed, the descendants of which bear her original name. Those pastoral tribes, when a foal is born, receive it in their arms, and so cherish it for several hours, stretching its tender limbs, and caressing it as if it were a child; and when it is placed on the ground, they watch its feeble steps, prognosticating its future excellencies or defects. The colt is mounted after its second year, after which it is fed upon barley, which is the usual provender throughout Arabia, though in Nedjed the horses are regularly fed on dates; and the wealthy inhabitants give them flesh, raw as well as boiled, and all the fragments of their own meals. In other respects they are hardly treated. They remain in the open air during the whole year, with the saddle constantly on their backs, and are not even taken under the shelter of the

[1] Burckhardt's *Travels in Arabia*, vol. ii. Appendix.

Arabia.

tent in the rainy season, or during the heat of the mid-day sun; yet with all this treatment they are seldom ill. The Arabs never clean or rub their horses; but they are careful to walk them about gently on their return from a ride. They prefer mares for riding, on account of their more patient endurance of fatigue, hunger, and thirst, than horses, and because they are gentler and less vicious, and never neigh when they are lying in ambush to surprise passengers. According to Burckhardt, the finest race of Arabian blood horses may be found in Syria; and of all the Syrian districts the breed in the Hauran is the best. But all the horses of the noble breed are not equally distinguished. Among these there are only a few, perhaps not above five or six in a whole tribe, of the first-rate class in respect to size, bone, beauty, and action. In the whole extent of the Syrian deserts there are not, according to the estimate of this traveller, more than 200, worth, even in the desert itself, about L.150 or L.200 each; and of these very few, if any, have ever found their way to Europe, although many horses of second and third-rate quality from Syria, Barbary, and Egypt, have been imported into England, and have passed for the pure Arabian breed. The price of horses in Syria is from L.10 to L.120. An Arab mare cannot be obtained under L.60: a celebrated mare will often bring from L.200 to L.500. A mare is frequently the joint stock of two, three, four, or any greater number of proprietors; and when she has foaled, the colt is sold, and the price is divided among the proprietors. Burckhardt mentions a scheik who had a Nedjed mare, for the half of whose belly, according to the phraseology of the Arab market, he paid L.400. D'Arvieux mentions an emir who "had a mare that he would not part with for 5000 crowns, because she had travelled three days and three nights without drawing bit, and by that means got him clear off from those that pursued him." A similar anecdote is told of a troop of Druses, who, having attacked an Arab encampment, were assailed by a superior force, and all killed except one man, who fled, and was pursued by some of the best mounted Bedouins. "But his mare, although fatigued, continued her speed for several hours, and could not be overtaken. Before the pursuers gave up the chase, they cried out to the fugitive, promising him quarter and safe-conduct, and begging him that he would allow them to kiss the forehead of his excellent mare. Upon his refusal they desisted from pursuing, and, blessing the generous creature, they exclaimed, addressing her owner, "Go and wash the feet of your mare, and drink up the water;" a phrase by which the Bedouins express their sense of the invaluable services rendered by those fine animals.[1] The Arabs treat the mares which they keep for riding with invariable tenderness. They never beat them, but make much of them, reason with them, talk with them, and take all imaginable care of them. They never spur them, except in cases of peculiar urgency, when the generous animal flies over the plains with so rapid a motion that the rider is apt to be stunned. Many curious instances are given by travellers of the care and affection with which the Arabs treat their horses. An affecting anecdote is related of an Arab, who having sold the half of a mare renowned for beauty and other fine qualities, for 1200 crowns, made frequent journeys to inquire after her welfare. "I have many a time," says D'Arvieux, "had the pleasure to see him cry with tenderness, whilst he was kissing and caressing her. He would embrace her, would wipe her eyes with his handkerchief, would rub her with his shirt-sleeves, would give her a thousand blessings during whole hours that he would be talking with her. 'My eyes,' would he say to her, 'my soul, my heart, must I be so unfortunate as to have thee sold to so many masters, and not to keep thee myself? I am poor, my Antelope; I have brought thee up like a child; I never beat nor chid thee. God preserve thee, my dearest; thou art pretty, thou art sweet, thou art lovely; God defend thee from the looks of the envious!' He then embraced her, kissed her eyes, and went backwards, bidding her the most tender adieus. Another Arab, who had sold his mare and put the money in the bag, looked wistfully on the animal, and began to weep. 'Shall it be possible,' said he, 'that, after having bred thee up in my house with so much care, and had so much service from thee, I should be delivering thee up in slavery to the Franks for thy reward!' on which he threw down the money on the table, embraced and kissed the mare, and took her back to his tent."[2]

Camels.

The camel is an invaluable animal in Arabia, being peculiarly qualified, by its power of enduring thirst and fatigue, for traversing its burning plains. The camels of the Arabian and Syrian deserts are of a smaller make than those of Anatolia or Kurdistan and other northern countries, and they have only one hump. They are used either for the purposes of riding, or for carrying heavy burdens. The smaller and more active camels, or dromedaries as they are termed, or in Arabia *deloul*, which are used for riding, are the same race as the heavier camels, which are employed in carrying burdens, being merely distinguished as a hunter is from a coach-horse. The common load of an Arabian camel is from 400 to 500 pounds on a short journey, and from 300 to 400 pounds when the distance is greater. The Egyptian camel, which is equal in strength to the Anatolian, will carry a load of three bales of coffee, equal to 1500 pounds, from Cairo to the water-side, a distance of three miles. The dromedary, or the riding camel, is used in travelling, though in speed it is far surpassed by the horse. Incredible stories are told of the wonderful expeditions performed by these animals. Burckhardt was assured by a Bedouin that his grandfather made a journey on a camel of 250 miles in one day; and he himself mentions that, on a wager, a camel was engaged to go in one day, between sunrise and sunset, a space of 125 miles; and actually travelled in 11 hours 115 miles, when its strength failed. The rate of speed at which a camel goes, even on a gallop, which is not his natural pace, and cannot be maintained above half an hour, is never more than 16 or 18 miles in the hour. In trotting, 12 miles an hour is the utmost limit of his speed, which may be continued for several hours. But a camel will carry his riders without interruption for several days and nights, in an easy and gentle amble, the favourite pace, at the rate of about 5 or 5½ miles in the hour, and will travel for five or six days 10 or 11 hours each day. A sort of palanquin is fixed on the backs of these camels for women, in which they are concealed from the public eye, and may stretch themselves at full length. The capacity of bearing thirst varies considerably in the different races. The Arabian camel must be watered on the evening of every fourth day. Some animals, though they may go five days without drinking, cannot be safely exposed to such a trial. The caravan routes are never at a greater distance than three or three and a half days' journey from water; but the caravans from Arabia to Egypt travel, during the heat of summer, through deserts in which water is wanting, for nine or ten days; and though many camels perish, the greater number come safely to Egypt. The Turcomans

[2] D'Arvieux, chap. xi.

Arabia.

and Kurds purchase every year from 8000 to 10,000 camels in the Syrian deserts, of which the greater part are brought originally from Nedjed. The price of a camel varies almost in every place. In Hedjaz a common riding camel may be bought for 50 or 60 dollars, and for some of the first quality 200 and even 300 dollars are sometimes paid.

The wild ass is found in great numbers in the country adjoining the district of Djof, to the west of Djebel Shammar, between Tobeck, Sauan, and Hedrush, and to the south of those places. It is hunted by the Arab tribes, who eat its flesh, and sell its skin and hoofs to the pedlars of Damascus and to the people of Hauran. Out of the hoofs rings are made, which are worn by the peasants as a charm against rheumatism. The domesticated ass in Arabia, as in all the other countries of the East, is a strong, active, and spirited creature, the rival of the horse in utility, if not in beauty. It retains all the strength, swiftness, and fire of the wild animal.[1] Arabia is not famous for horned cattle. The cow is used, however, in many places, for drawing water from the wells, and other purposes. It is small, and of a stout, bony make, with short stumps of horns, and a hump on the back over the shoulder, like the cows on the Nile and in Nubia.[2] The northern tribes of Arabia, namely, the Aenezes, and the Ahl el Shemal, possess abundance of goats and sheep. The goats are mostly black, with long ears. The sheep have not the fat tails of those that are found in some countries; their ears are rather longer than those of the common English breed. The Arabs use in their families the milk of their flocks. They also make great quantities of butter, part of which they sell to the peasants and town's people.

Birds.

Arabia produces a considerable variety of birds. In the fertile provinces tame fowls abound, and all sorts of poultry. The pintado inhabits the woods in such numbers that children kill them with stones and collect them to be sold in the towns. In the forests of Yemen pheasants abound; also the wood-pigeon, and other varieties of the same species. In the plains is found the gray partridge, the common lark, the wild goose, and a species of white crane having the under part of the belly of a beautiful red. Eagles, falcons, sparrow-hawks, and the Egyptian vulture, are the Arabian birds of prey. The last clears the country of all carrion, and also of field mice, which multiply prodigiously in some provinces. There is another bird of prey, of the thrush species, which is equally useful in pursuing and destroying the swarms of locusts with which the country is infested. There are various birds which are little known, and which are supposed to be birds of passage from India, distinguished by peculiar brilliancy of plumage. There is one which has two large and beautiful feathers, with which the Arabians adorn their caps; and another which, for its rare beauty, is sold for a high price. A beautiful lapwing is common on the shores of the Persian Gulf. The sandy tracts of the desert abound in ostriches: these are hunted by the Arabs for their feathers, which form a valuable article of trade. The ostrich inhabits both the great southern and northern deserts. They abound in the plain extending from Hauran towards the central provinces of Djebel Shammar and Nedjed. Some are seen in Hauran, and a few are taken almost every year within two days' journey of Damascus. They generally breed in the winter, and the Arabs discovering the nest, scare away the birds, when they resort to the following contrivance for destroying them:—A hole is dug in the ground near the eggs, into which the Arab places a loaded gun, with a long burning match fastened to the lock. The ostriches resume their place generally both at once on the eggs: in due time the gun is discharged, and next morning the Arabs find one or both of the ostriches laid dead beside the eggs. The feathers are sold at from L.2. 6s. to L.2. 10s. per pound, and the finest at from one to two shillings each. In places where there is water, plovers and storks abound; and sea-fowls, feeding on fish, are numerous on the coasts of the Red Sea, which is deep, and copiously stored with their food. Here, and on the isles along the shore, the pelican is to be found.

The heat of the climate favours the breed of serpents, some of which only are dangerous, while others are perfectly harmless. The only one that is truly formidable is a small slender creature, with black and white spots, whose bite is followed by instant death, and an extraordinary swelling of the body from the malignity of the poison. Of the insects in Arabia, the most remarkable as well as the most destructive is the locust, which flies in swarms that darken the air, and with a frightful and stunning noise, such as is made by a water-fall. The fields are entirely despoiled of their verdure by these insects. The pulse and the date trees are also greatly injured; but the corn, when it is nearly ripe, resists, by its hardness, their attacks. Locusts are found in all parts of the Arabian deserts. They come invariably from the East,—from the waters of the Persian Gulf, according to the notions of the rude Arabs. In the central province of Nedjed they not only destroy the produce of the fields, but penetrate by thousands into private dwellings, where they devour whatever they can find, even to the leather of the water-vessels. In the peninsula of Sinai the inhabitants are driven to despair by swarms of locusts, which consume the fruits of the earth. All the Arab tribes, as well as the inhabitants of towns, are accustomed to eat this insect; and at Medina and Tayf there are shops in which they are sold by measure. After being salted, whole sacks are filled with them. The destructive insect the white ant, which preys upon victuals, clothes, furniture, and the leaves of trees, is common. There is another ant, whose bite is like that of the scorpion, although it is not dangerous. The scolopendra affects those whom it attacks with burning pains. It fixes its feet so firmly in the flesh that it cannot be got out but by burning the part with a hot iron. Other insects destroy reeds and stalks of corn, and make their way into houses. There are many species of crabs, some of them peculiar to the Red Sea, which are excellent, and, but for the peculiar aversion of the Mussulmans to shell-fish, would afford a wholesome subsistence. At Suez they form almost the sole food of the Copts.

Minerals.

Arabia has never been noted for its minerals. It was supposed by the ancients, who had the most exaggerated ideas of its wealth and produce, to abound in precious stones, as well as gold and silver. Except it be the onyx, which is found in Yemen, and the carnelian, it produces no other stones of value; iron ore seems to be abundant in parts of Yemen, and indications of many other minerals have been found in Hadhramaut. There are mines of fossil salt among the mountains, which were formerly worked, but are now neglected; and the iron of Yemen is found to be of a coarse quality and brittle. In Oman are very rich lead mines, the produce of which is largely exported from the harbour of Mascat, in the Persian Gulf.

Arab tribes.

Burckhardt, whose posthumous work[3] contains the most ample and satisfactory details of Arabian manners, gives a

[1] Niebuhr, vol. ii. chap. iii. Burckhardt's *Notes on the Bedouins and Wahabys.*

[3] *Notes on the Bedouins and Wahabys.*

Arabia.

particular classification of the Bedouin tribes. Those who inhabit northern Arabia he distinguishes into two classes; namely, the Aenezes, who migrate with the spring and summer to the fertile parts of Syria, and return with the winter to the desert; and others, who remain the whole year in the vicinity of the cultivated tracts. The Aenezes, reckoning their brethren in Nedjed, form one of the most powerful associations of shepherds in the Arabian deserts. They levy contributions on the Syrian villages, as well as on the pilgrim caravan in its passage from the desert to Mecca; and their numbers are estimated at from 300,000 to 350,000, and their military force at 10,000 horsemen, and from 90,000 to 100,000 camel-riders.

There are numerous other tribes in northern Arabia, scattered along the frontiers of Syria and the banks of the Euphrates. They are not so migratory in their habits as the Aenezes, with whom several of them carry on the most deadly strife, while others pay a yearly tribute to all the chief Aeneze tribes, and in some cases to the pacha of Damascus. Many of them cultivate the land though they dwell in tents; and those on the borders of Syria carry their produce of milk, butter, and cheese to the market of Aleppo. There are other tribes that range over the country to the south, over the mountains that run in a direction parallel to the Red Sea as far as Medina and Mecca, or in the interior plains and mountains of Djebel Shammar, Kasym, and Nedjed. Some of those tribes, as the Beni Shammar, can muster from 3000 to 4000 men, armed with matchlocks; others, such as Meteyr, who occupy the fruitful pastures of Nedjed, 1200 horse, and from 6000 to 8000 matchlocks. The country from Kasym towards Medina and Mecca, and the coast southward from Yembo to Djidda and Leith, for about 250 miles, is inhabited by the Beni Harb, which, next to the Aenezes, is the most powerful tribe in Arabia. They can muster from 30,000 to 40,000 men, armed with matchlocks. The Harbs are partly settlers and partly Bedouins. They may be styled the masters of the Hedjaz, and were the last tribe in those countries that yielded to the Wahaby arms. They take a yearly tribute from the Egyptian and Syrian caravans; and they extend their predatory inroads against the encampments of the Aenezes to the vicinity of Damascus. On the sea coast, where the territory is poor, they derive a subsistence from fishing; and many of them are sailors, and act as pilots between Yembo and Djidda. But these tribes, from their intercourse with the inhabitants of towns, and their maritime habits, are regarded with disdain by the genuine Arabs. To the east of Mecca and Tayf, in the fruitful pastures of the interior, resides the brave and powerful tribe of Ateybe, the inveterate enemies of the Beni Harb, who can muster a force of 10,000 matchlocks. In the neighbourhood of Mecca are many well-known tribes, now reduced to about 250 or 300 matchlocks. The tribe of Koreish, so famous in the Arabian annals, who encamp near Mount Arafat, now amount only to 300 matchlock-men. The tribe of Adouan, which 40 years ago mustered about 1000 matchlocks, and were celebrated all over Arabia for their valour and hospitality, are now reduced to 100 families. It is to this tribe that the reigning sherifs of Mecca send their children to be educated. In the mountainous region between Mecca and Tayf reside the warlike tribes of the Hodheyl, mustering 1000 matchlocks, famed as excellent marksmen, brave soldiers, and daring high-way robbers; the Toweyrek, who muster 500 matchlocks, and have the character of dexterous thieves; and the Thekyf, who possess the garden country around Tayf, and the other equally fertile valleys on the eastern declivity of the great Hedjaz chain of mountains. The wealth of these mountain tribes consists in flocks of sheep and goats. They suffered severely, especially the Hodheyl, in their obstinate but unavailing resistance to the Wahabys. From Tayf southward, along the eastern face of the great chain of mountains to Sana, are several ancient and powerful tribes, renowned in Arabian history. Some are partly cultivators and partly Bedouins. The Beni Kahtan and the Beni Sad are famous from the most remote antiquity. The former is exclusively pastoral, abounding in camels above any other tribe of the desert. Some of these southern tribes can muster from 500 to 1500 matchlocks. They are brave and warlike, and they extend from the mountains over the eastern and western plains. The tribe of Asyr can assemble 15,000 men, armed with matchlocks. Of the various tribes scattered over the mountains of El Shehr or Mahra, and the countries that are washed by the Persian Gulf, we have no detailed or accurate accounts. The tribes in the mountains are, however, in general employed in agriculture; many of them live in tents, and descend in spring into the neighbouring plains for pasture to their flocks. The cultivators dispose of their produce, which is abundant, in the towns on the coast.

Manners and character of the Arabs.

Arabia has been celebrated from time immemorial as the seat of independence and of pastoral simplicity, and it is perhaps the only country in the world which, until it was lately overrun by the troops of Mohammed Ali, was never profaned by foreign conquest. Mountains and deserts, as is well observed by Sir John Malcolm,[1] have been in all ages the sanctuaries of the brave and the free; and thither the hardy Arabs, when pressed by powerful armies, have always fled to enjoy freedom and independence. On the sea coasts and in the towns the Arab character has been corrupted by commerce and a free intercourse with foreigners; but in those secure recesses the ancient manners of the country are still to be found. The genuine inhabitants of the desert unite the character of shepherds and soldiers. They live in tents, and they subsist by maintaining flocks of sheep and camels, and also cows and horses. The larger tribes are chiefly employed in rearing camels, which they either sell to their neighbours, or employ in the carriage of goods or in military expeditions. The petty tribes maintain flocks of sheep. They disdain the cultivation of the ground, as an employment degrading to a pure Arab, and which they accordingly leave to the inferior race of peasantry and slaves. These Bedouins live the usual vagrant life of shepherds, emigrating from one place to another with the change of the seasons, in quest of pasturage, and transporting their dwellings along with them; so that a village arises often in a situation where, an hour before, not a hut was to be seen. The genuine Arabs, who live constantly in the open air, acquire a remarkable acuteness in all their senses. Their powers of vision and of hearing improve by constant exercise; and on the vast plains of the desert objects invisible to a less practised eye are at once seen by them. Their sense of smelling is extremely acute; and their dislike to a town life is occasioned by the nauseous exhalations which are produced among such a dense collection of people. The Arabs possess the same faculty of nicely distinguishing on the sand the footsteps of men and beasts which the American Indians distinguish on the grass. To such perfection have they arrived in this art, that an Arab will at once recognise the footstep of any one of his own or of some neighbouring tribe; he will know

[1] *History of Persia.*

whether the person carried a load; whether he passed the same day, or a day or two before; whether, from a certain irregularity in the steps, he was fatigued, had come from a distance, and how far he has any chance of overtaking him. He knows at once the footsteps of his own camel—whether it was heavily loaded, or mounted only by one or more persons. A keen Arab guide has his eye constantly on the footsteps which he sees; and Burckhardt mentions that he has seen a man discover and trace the footsteps of his camel amid thousands of other footsteps crossing the road in every direction, and, by an inspection of the footsteps, tell the name of every person who had passed there in the course of the morning. Many secret robberies are brought to light by this power of nice observation. Instances have been known of stolen camels found after a journey of six days; and so long as the traces of men or camels can be seen on the sand by the practised Arab's discriminating eye, robberies are almost sure of detection. So thoroughly are the Bedouins inured to fatigue and the want of water, that they will wander about five days without tasting it, and will at last discover a pit of water by examining the soil and plants in the environs. They ride on horses and camels, and are continually armed with a lance, a sabre, and sometimes a matchlock or a pistol. Some of them wear coats of mail. All those wandering shepherds are addicted to violence, and to the fierce habits of a military life. They are either engaged in open war about their wells or pasture grounds, or in plundering excursions or secret robberies, which they do not consider to be in any degree criminal; and no more flattering title can be conferred on an Arabian youth than that of robber. The defenceless traveller, whom they descry from afar on the level plain, is marked out for their prey. He is seized, stript of every thing, and left naked in the desert. If he resists, and more especially if he sheds the blood of a Bedouin, they take his life. But the Arab plunders sometimes strangers and neighbours, enemies and friends, provided they are not actually in his own tent; in general, thieves convicted of robbery against a fellow clansman are expelled from their tribe and outlawed, a punishment which they fear more than death. Associations are frequently formed for the plunder of caravans, or of the cultivators who dwell in villages, whose cattle they carry off, and sometimes, though very rarely, their young women. In those cases they proceed with a considerable force. Their chief object, however, being still plunder, the great point of Arab tactics is to surprise the enemy's encampment, and to carry off the cattle and the camels. They seldom engage in any sanguinary conflicts; for though the Arab, in facing the enemies of his country, behaves like a brave soldier, he is a mere poltroon in his plundering expeditions; and the caravan travellers and peasants frequently put to flight three times their own number of those wandering robbers. In undertaking an expedition for plunder at the distance of ten or twenty days' journey, every horseman who is of the party chooses a companion, who is mounted on a young and strong camel, and who carries a provision of food and water. He mounts behind this companion, that his mare may be fresh and vigorous at the moment of attack. In approaching the enemy's camp, the horsemen advance, leaving their followers and the camels behind, with instructions to await their arrival. The horsemen are sometimes all destroyed in the expedition; and they are at other times separated from their followers who carry the provisions, and either inevitably perish in the barren plain, or submit to be stript and plundered by their enemies. In the most inveterate wars of the Arabs the women are invariably respected; and neither men, women, nor slaves, are taken prisoners. Night attacks are generally avoided, lest during the confusion the women's apartments should be entered, which would produce a desperate resistance, and probably in the end a general massacre—an extremity which the Arabs always try to avoid. The attack of a camp seldom occasions any great loss of lives, because no opposition is offered to superior numbers; and a Bedouin, except in avenging blood, never puts to death an unresisting foe. In flying from his enemy, an Arab may save his life by throwing himself from his horse and asking for mercy; but he saves it at the expense of his honour, and loses his horse and all his clothes, while his enemy will ever after triumph over him. The more spirited of the Arabs defy their adversary, while he pursues them, calling out repeatedly, "Howel, howel," get down, get down, and who, when his call is not obeyed, wounds or kills his enemy with a thrust of his lance. Among some of the Arab tribes it is the practice to steal unobserved on the enemy's encampment during the night, and knocking down the principal tent-poles, to drive off the cattle amid the confusion.

But the Arabs often undertake merely thieving expeditions, in which they steal from friend and foe. The mode in which these are conducted affords some curious details of manners. In such enterprises ten or twelve persons usually engage, and clothe themselves in rags, to make their ransom easier if they should be taken. When they approach the camp which they intend to rob, three of the most daring advance about midnight, when its inmates, who seldom plant sentinels, are buried in sleep. One of the thieves now endeavours to excite the attention of the watch-dogs. When they attack him he flies, and draws them off to a great distance, by which the camp is left unprotected. Another, called *el haramy*, or the robber, advancing towards the camels that are upon their knees before the tent, cuts the strings that confine their legs, when they rise and walk, as all unloaded camels do, without the least noise. One of the she camels being then led out of the camp, all the others follow. The third actor in the robbery watches at the tent door with a long and heavy bludgeon, with which he knocks down any of the inmates who may come forth. It often happens that as many as fifty camels are stolen in this manner, and driven away by forced marches during the night to a safe distance. In many cases, however, the robbers are surrounded and seized; and the mode of treating these prisoners is extremely curious, and is a proof how powerfully these fierce barbarians are influenced by prejudice and immemorial usage. It is an established custom among the Arabs, that if any person who is in actual danger from another can touch a third person, or any inanimate thing which the other has in his hands, or if he can touch him by spitting or throwing a stone at him, and at the same time exclaims "I am thy protected," he is bound to grant him the protection which he requires. This law, however absurd and capricious, seems naturally to arise out of scenes of violence, the evils of which it is calculated to soften. A prisoner detected in the act of plundering anxiously looks about for a protector, while the inmates of the tent are equally desirous to deprive him of this privilege. The person who first seizes him demands on what business he is come, accompanying his question by blows on the head. "I came to rob—God has overthrown me," is the common answer. The captor (the *rabat*), binding the hands and feet of his prisoner, and calling in the people of his tribe, addresses him, saying, "renounce;" and the robber, fearing a continuation of the blows, answers, "I renounce," namely, the benefit of any protector. But this renunciation being only valid for a day, the prisoner is secured in a hole dug

in the ground, about two feet deep, and large enough to contain him. Here he is laid, his feet chained to the earth, his hands tied, and his twisted hair fastened to two stakes on both sides of his head. Some tent-poles are then laid across this temporary grave, and corn-sacks and other heavy articles heaped upon them; a small opening being only left, through which he may breathe. Thus buried alive, the prisoner does not despair; and customs that are established among the Arabs sometimes favour his escape. If from his hole he can contrive to spit into the face of a man or a child, or if he receive a morsel of bread from a child, he claims the privilege of being protected. His mother or his sister sometimes contrive to enter the camp in which he is confined, in the disguise of a beggar. Approaching during the night the hole where he lies confined, and throwing a thread of worsted over his face, they guide it to his mouth, or fasten it to his foot; and by this token he knows that help is at hand. The woman winding off the thread, retires to some neighbouring tent, and awakening the owner, and placing the thread on his breast, addresses him in these words: "Look on me by the love thou bearest to God and thy own self—this is under thy protection." The Arab comprehends at once the object of this nocturnal visit, rises, winds up the thread, and being thus guided to the tent of the prisoner, awakens the captor, and showing the thread still held by the prisoner, claims him as his "protected." The right of freedom is at once allowed; the thongs which tied his hair are cut, his fetters are taken off, and he is entertained by the captor as his guest with all the honours of Arab hospitality. A prisoner sometimes remains for six months under this rigorous custody, always concealing his real name, and giving himself out for a poor beggar. He is generally discovered, however, when he must pay as a ransom all his property in horses, camels, sheep, tents, provisions, and baggage. In many cases a sum is agreed upon for his ransom, and he goes to his tribe to collect it, or find a surety for the payment. If he cannot collect the necessary sum among his friends, he is bound to go back to his prison; and he seldom fails either to pay or to return. A father considers his son to have acquired high honour in being detained as a robber, and he willingly redeems him with his whole property, which he hopes to recover in some future expedition.

Nobility of Arabia.

The Arabs are remarkable above all the nations of the earth for the spirit of clanship and for pride of family. The scheiks, or the rulers and nobles who govern Arabia, glory in their ancestry, which they can trace with undoubted accuracy to a long line of princes. Nobility of birth, which cannot be communicated by the smile of kings, is the true distinction of the Arabian aristocracy; and no scheik would exchange his title for any distinction depending on court favour. Those genuine nobles, who dwell in tents, look with contempt on the dwellers in cities, as a race debased by foreign alliances, which they hold in such contempt, that a scheik, if he were forced from poverty to marry his daughter to a citizen, would consider himself disgraced by the match. Besides the scheiks there are the sherifs or sejids, or, in the Mahometan countries to the north of Arabia, the emirs. These are the descendants of Mahomet, who hold the first rank among the great families of Arabia, and who receive the double honour that is due to splendid descent and superior sanctity. The title of sherifs distinguishes them from the scheiks, the common order of Arabian nobility. They are multiplied over all Mahometan countries. Whole villages are peopled with them, and they are frequently found in the lowest state of misery. The sherifs of the Hedjaz, who were once numerous, but are now reduced to a few families in Mecca, have never contaminated their pure blood by strange alliances; and they are esteemed above all the other descendants of the prophet. The presence of a sherif commands universal respect. In a fray no arm would violate his person; his property requires no protection; the sanctity of his character supplies the place of bolts and bars, and scares away the boldest thieves.

From these sherifs are chosen the rulers of Mecca and its adjacent territories, extending for about 250 miles along the coast, from Yembo on the north, to Haly or Gonfode on the south. Before the country was conquered by the Wahabys, and again by the Turkish troops under Mohammed Ali, they possessed the power of sovereigns within their dominions; and though they held their authority ostensibly under the grand signior, being installed in their office by an investiture of a pelisse from Constantinople, thus formally acknowledging themselves his servants, and praying for him in the great mosque, they were in reality elected by the powerful sherif families resident at Mecca, and they ruled according to the constitutional maxims of the desert, merely as Bedouin chiefs. The Arab tribes looked upon them as one of their own scheiks, the head of the family or clan; and they followed them in war under their own immediate chiefs, without receiving pay. In this manner Ghaleb, the last sherif, was accompanied in his wars against the Wahabys by 6000 or 8000 Bedouin Arabs. A system of well-regulated freedom was not to be expected from the rude policy of wandering shepherds, and the Arab chiefs accordingly own no restraint on their authority. But the rigour of despotic sway is softened by the influence of manners; and the independent princes of Mecca, in the pride of sovereignty, still acknowledge the ties which bind them to the simple Bedouins of the desert. The sherif descendants of Mahomet who reside at Mecca retain a singular practice of sending every male child, eight days after it is born, to the tents of some wandering tribe. Here he remains till his 8th or 10th year, when he is able to mount a steed, and sometimes till his 13th or 15th year. During all this period he only pays one short visit to his father's house, in his sixth month, when his foster-mother returns with him to her tribe. The boy is trained by those shepherds in all warlike exercises: he shares in their hardships and perils, is familiarized with their manners, and acquires their pure language, and a lasting influence over them; while his affections, awakened at an age when the mind is peculiarly susceptible, still attach him to the scenes of the desert and the companions of his youth. The tent of a Bedouin shepherd is in this manner the constitutional school of an Arabian prince, in which he imbibes the maxims by which he afterwards rules the state. Some of the sherif boys become so fond of their foster-parents that they can scarcely be reconciled to their fathers' house; and they have been sometimes known, after being settled at home, to escape to their friends in the desert. "The Bedouins," says Burckhardt, "in whose tent a sherif had been educated, were ever after treated by him with the same respect as his own parents or brethren: he called them respectively father, mother, brother. Whenever they came to Mecca they lodged at his house, and never left it without receiving presents. He considered himself during his life as belonging to the encampment in which he had passed his early years; he termed its inhabitants 'our people,' or 'our family,' took the kindest interest in their various fortunes; and, when at leisure, often paid them a visit during the spring months, and sometimes accompanied them in their wanderings and their wars." Sherif Ghaleb, whose reign was terminated by Mohammed Ali in 1815, was remarkably attentive to

his Bedouin friends. They alighted at his house in Mecca just as they alight at the tent of a scheik in any Arab encampment of the desert; and when they departed, their sacks were filled with provisions for the road. On their arrival he used to rise from his seat and embrace them, though they were in the same mean attire as the other inhabitants of the desert. Many of the sherifs are also married to Bedouin girls.

A sherif was generally succeeded by his relative, whether son, brother, or cousin, who had the strongest party, or the public voice in his favour; but it was seldom that an election took place without a violent contest, which frequently ended in bloodshed and civil broils. These, however, were carried on according to the laws of the desert, and they were seldom of long duration. The happiness of the people under these sherifs always depends on the personal character of the ruler. There are no tribunals to which the oppressed can fly for redress, and a sherif may harass his subjects to any extent by his extortions. He may imprison the refractory, and even put them to death, without endangering his authority. Such is the despotic character of all eastern governments.

In the Ottoman provinces the dignity of sherif is less respected, though even in Turkey they enjoy some substantial privileges. In the towns where they reside, the sherif or emir is subject, not to the pacha, but to a member of his own family, who is denominated nakib or general of the sherifs. Besides the scheiks and sherifs there is another branch of nobility at Mecca, who have an hereditary right to certain employments at the mosque, and who have a strong inducement to preserve an exact record of their genealogy. These are certain families descended from the tribe of Koreish, who hold the office of keeper of the keys of Kaaba, which is the most important office about the mosque, and was often an object of contention among the ancient Arabian tribes; and others who are muftis, or are employed in other capacities, and who, to preserve their title to these envied privileges, can show a faithful record of their ancestors for ten centuries back. There were formerly 12 other illustrious families of the tribe of Koreish, who are now reduced to three.[1]

Government.

Arabia is divided into numerous petty states, governed by independent chiefs or scheiks, who are, strictly speaking, the heads of families; and the paternal government thus supplies the model of the Arabian institutions. The father is in all cases the natural ruler of his own family; and though the tie be necessarily weakened as families multiply, yet the relations of kindred and of blood are still acknowledged, and all the descendants unite in paying respect and reverence to their common head. An assemblage of families constitutes a tribe; and all the scheiks of the same tribe acknowledge a common chief, who is called the *schech es scheuch*, or the scheik of scheiks, or the grand scheik or prince, who rules over the whole. The dignity of the grand scheik is hereditary in the family; but it is so far elective that he is chosen by the inferior scheiks, from the whole members of the reigning family, without regard to seniority or lineal succession: his only distinction is his qualification for the office. The right of election, as well as other privileges which belong to the inferior scheiks, obliges the grand scheik to treat them rather as associates than as subjects, and in some measure to share with them his sovereign authority. If they are aggrieved by him, they depose him, or emigrate with their cattle to other tribes; and in this manner many powerful tribes have been weakened, while the number and the power of others have been augmented.

The scheik has in fact no acknowledged or formal authority over his tribe. His commands would be treated with contempt, and his advice only is received with the deference due to experience and talent. "The prerogative of the scheik," says Burckhardt, "consists in leading his tribe against an enemy, in conducting negotiations for peace or war, in fixing the spot for encampments, in entertaining strangers of note; and even these privileges are much limited. The scheik cannot declare war or conclude peace without consulting the chief men of his tribe. If he wish to break up the camp, he must previously ask the opinions of his people concerning the security of the roads, and the sufficiency of pasture and water in the districts to which he directs his view. Thus he strikes his tent and loads his camels without desiring any one to do so; but when they know that the scheik is setting out, his Arabs hasten to join him." The Arabs are jealous of authority, and their freedom borders on anarchy. The Bedouin acknowledges no master but the Lord of the universe; and the most powerful chief, by inflicting punishment on the poorest man of his tribe, is exposed to the mortal vengeance of himself or his relations. A scheik, in place of deriving a yearly income from his tribe, is bound to show liberality, especially in his treatment of strangers; to maintain the poor, and to divide among his friends whatever presents he may receive. The only revenue possessed by the northern chiefs is the tribute which they extort from the Syrian villages, and from the pilgrim caravan to Mecca. Among the numerous principalities in the south of Arabia, the scheik or imam imposes a land tax and a poll tax, also port and transit duties on all articles of merchandise, some of which, as on coffee, are very heavy. These duties on goods are not, as they have been sometimes considered, a mere ransom from pillage, but a tax and an acknowledgement of the paramount authority of the prince. Among so many petty sovereignties wars frequently arise, from the ambition or jarring interests of the different chiefs. The more powerful princes frequently oppress their weaker neighbours; and in the fertile districts of the country extensive monarchies have arisen from conquest or religious prejudices, on the ruin of the smaller states. Of these are the dominions of the sherif of Mecca, and of the imams of Sana and Mascat; many sherifs are under the control of the Bedouins. In some cases these smaller states have associated for their common defence; and, from the disunion or hostility of its various tribes, the country has been in all ages a scene of rapine and intestine wars. In later times the rise of the Wahaby power crushed all the inferior chiefs, and on their ruins had arisen a powerful empire, which was overthrown by the Egyptian army of Mohammed Ali.

Administration of justice.

The Arabs, though they enjoy a rude independence, have made little progress in the arts and institutions of civil life. In administering justice, they resort to the most barbarous expedients. The scheik has not the power of enforcing obedience to any sentence if it is not agreed to by the parties. The kady, so often mentioned by the Arabian writers, is the only judge; and such of them as still remain are famed for being expert in the laws and customs of the nation, and for their integrity. The office of kady continues in one family, but is not confined to any individual, a choice being made of the fittest person in the family by the other kadys of friendly tribes, as well as by the people of his own tribe. The kady is paid by the litigating parties; but all the judges, especially those in towns, are open to bribery, and justice is sold to the highest bidder. In cases where the witnesses directly

[1] Burckhardt's *Travels in Arabia*, vol. ii. p. 127.

contradict each other, some superstitious ordeal is used to discover the truth. A particular judge is appointed for cases which must be decided by supernatural means. He directs that a fire shall be kindled before him: "he then," says Burckhardt, "takes a long iron spoon, used by the Arabs in roasting coffee, and having made it red-hot in the fire, he takes it out, and licks with his tongue the upper end of the spoon on both sides. He then replaces it in the fire, and commands the accused person first to wash his mouth with water, and next to lick it as he had done. If the accused escape without injury to his tongue he is supposed innocent; if he suffer from the hot iron he loses his cause. The Arabs ascribed this wonderful escape, not to the Almighty protector of innocence, but to the devil." In all cases of manslaughter or murder where the fact is denied, this superstitious ordeal is appealed to, and no other mode of trial admitted. Where the parties refuse the decision of the judge, they resume their original right of avenging their own quarrel; and a strife of this nature once begun, and producing blood-shed, leads to a long series of cruel retaliations.

Among the Arabs crimes of every description are punished by fines; corporal punishments are entirely unknown; and there are no prisons to circumscribe the freedom of the desert. For every offence a fine is fixed in the kady's court, which is rigidly exacted: all insulting expressions or acts of violence, from a slight blow to wounding and the effusion of blood, have their respective penalties. They adopt the following singular mode of ascertaining the fine payable for killing a watch-dog: The dead dog is held up by the tail, so that its mouth just touches the ground; its length is then measured by means of a stick, which is fixed in the earth, and the offender is obliged to pour out over the stick as much wheat as will wholly cover it, which is then given to the owner of the dog. The form observed by an Arab in summoning witnesses is by exclaiming, "Bear thou witness, O ——;" or he may touch their arms with his hand, which is considered as a summons to give testimony. Where a party is accused of a crime, and there are no witnesses, the matter is referred to his oath. The judicial oaths of the Arabs have different degrees of sanctity; and for certain oaths they have a superstitious veneration, which induces them to tell the truth. One of the most common oaths is for a party to take hold with one hand of the middle tent-pole, and to swear "by the life of this tent and its owners." The following oath is often taken before the kady: A small piece of wood or some straw is presented to him who has to swear, with these words, "Take the wood, and swear by God, and the life of him who caused it to be green, and dried it up." Another oath, even more solemn, is the "oath of the cross lines," where the accuser leads the person accused of theft or any other crime to a distance from the camp, on account of the magical nature of the oath; and with his crooked knife drawing on the sand a large circle, with many cross lines inside of it, and obliging the defendant to place his right foot within the circle, he himself doing the same, he addresses him in the following words, which the accused is obliged to repeat: "By God, and in God, and through God, I swear I did not take it, and it is not in my possession."

A singular institution, that of the wady or guardian, prevails among the Arab tribes. An Arab may in the prime of life request a friend to act as guardian to his children. If he accepts the trust, his friend presents himself before him with a she-camel; and leading it over to him, says, "I constitute you guardian for my children, and your children for my children, and your grandchildren for my grandchildren." In this manner one family is constituted the hereditary protectors of another family; and thus this fierce and warlike community, the prey of continual dissension, is held together by its own peculiar ties, domestic as well as political. To the weak, such as minors, women, and old men, the system of guardianship affords some security, however imperfect, against the oppression of the strong.

Arabia.

Law of revenge for blood.

The Arabs are naturally a jealous and haughty people. They betray the quickest sensibility to an affront or injury, and carry the principle of revenge to the greatest excess. They consider the redress of their own wrongs as equally a duty and a privilege; and there are certain affronts and trifling violations of punctilio, which can only be expiated by the blood of the offender. To spit beside another is considered an insult which must be avenged; and Niebuhr mentions the case of an Arab who was so highly incensed at one of his neighbours for accidentally spitting on his beard, that he was with great difficulty appeased, although the offender humbly asked pardon, and kissed his beard in token of submission. If one scheik says to another with a serious air, "Thy bonnet is dirty," or "The wrong side of thy turban is out," it is considered a mortal offence. Murder is the deepest injury that can be committed; and the Arab code regulates the revenge for blood by the nicest rules. It is a universal maxim, that he who sheds blood owes on that account blood to the family of the slain person; and this debt may be required not only from the actual murderer, but from all his relations. These claims constitute the right of *thár*, or of "blood revenge." In the case of a slain parent, the fifth generation of his lineal descendants inherit the sacred duty of avenging his blood on a corresponding series of descendants on the other side; and this right is never lost by prescription, but descends to the latest posterity. If the death of the person killed is retaliated on one only of the murderer's family, the account is considered to be cleared, though mutual hatred soon renews the quarrel. If two of the murderer's family be killed by the relations of the deceased, the former retaliates; "the interest and principal of the bloody debt," says the great Roman historian, "are accumulated; the individuals of either family lead a life of malice and suspicion; and fifty years may sometimes elapse before the account of vengeance be finally settled." But a murder may be compounded for money. The nearest relations of the persons slain may accept the price of blood, which varies among the different tribes from 1000 piasters, or L.50, to 500 piasters. Among the Aenezes the blood of one of the tribe is compensated by 50 she-camels, one riding camel, a mare, a black stone, a coat of mail, and a gun; though it is seldom that all these articles are required: that of a stranger by the price paid in the stranger's tribe. The matter being finally settled, a she-camel is brought by the homicide to the tent of his adversary, and there killed, the blood being supposed to expiate that of the person slain. The hostile parties feast upon this camel; and at parting, the homicide flourishes a white handkerchief on his lance, as an emblem of his purity from guilt. Some of the great scheiks, however, account it shameful, and contrary to the true spirit of the Arab law, to compound the price of blood; and they invariably refuse to commute into a fine the sacred duty of revenge. Niebuhr mentions that he was visited by an Arabian of distinction at Loheia, who was bound to avenge the murder of a relation, and who told him that he was often haunted in his sleep by the fear of meeting his enemy. In the course of the continual wars in which the Arabs are involved, debts of blood are frequently incurred. The blood of those who are killed in the heat of battle is required at the hands of their

Arabia. enemies; and when any tribe violates the laws of war by slaughtering their enemies as they lie wounded on the field, the hostile tribe retaliate by killing double the number of their enemies with the same circumstances of cruelty; and hence long and bloody animosities frequently arise.

Tents. The tent of the Arab is covered with pieces of stuff made of goats' hair stitched together, which afford a complete shelter against the heaviest rain. The tent is divided into two parts, one for the men, and the other for the women, whose respective apartments are separated by a white woollen carpet of Damascus manufacture, drawn across the tent, and fastened to the three middle parts. The men's apartment is covered with a good Persian or Bagdad carpet; the women's apartment is the receptacle for all the rubbish of the tent, the cooking utensils, the butter, and water-skins, &c. The height of the tent is seven feet, its length from 25 to 30 feet, and its breadth about 10 feet. The articles of the tent consist of saddles and camel furnishings; large bags for holding water, made of tanned camel-skin; goat-skins for holding camel's milk, wheat-sacks made of wool or goat-hair; the leather bucket for bringing up water from deep wells; a large copper, the mortar, the hand-mill, wooden dishes, the coffee-pot, the iron chain which fastens the horse's fore-feet while he pastures about the camp. They have no chairs throughout the East, the universal practice being to sit cross-legged. In the Arabian towns the houses are built of stone, and have always terrace roofs. The houses of the tribes on the banks of the Euphrates are formed of the branches of the date-tree, and have a round roof covered with rush mats.

The dress of the Arabs is a coarse cotton shirt, over which the wealthy throw a long gown of silk or cotton stuff. Most of them, however, only wear over their shirt a thin, light, and white woollen mantle, or one of a coarser or heavier kind, striped white and brown. The mantles worn by the scheiks are interwoven with gold, and sometimes may be worth L.10 sterling. Some of the most considerable tribes, as the Aenezes, do not wear drawers, which are reckoned shameful for a man; and they usually walk and ride barefooted, even the richest of them, although they greatly esteem yellow boots and red shoes. They wear on their head a square kerchief of cotton: a few rich scheiks wear shawls of Damascus or of Bagdad manufacture. In winter they wear over the shirt a pelisse made of several sheep-skins stitched together. Many wear these skins even in summer, as they are taught by experience that thick clothing is a defence against the sun's rays. The Arab endures with wonderful constancy the extremes both of heat and cold. In winter he sleeps barefooted in an open tent, where the fire is not kept up beyond midnight; and in summer on the burning sand, under the intense rays of the sun. The dress of the women consists of a wide cotton gown of a dark colour—blue, brown, or black—and on their heads a kerchief. Silver rings are much worn by the Aeneze women, both in their ears and noses. They wear glass or silver bracelets, of various colours, round their wrists and their ancles, and silver chains about the neck. They go barefooted at all seasons. The women wear over their faces a dark-coloured veil, which conceals the mouth and chin. Near Mecca and Tayf, and beyond these places southward, both men and women dress most commonly in leather. They both wear a leather apron round their loins, the women a larger one than the men, reaching down to their ancles, and adorned with many tassels. In summer the men wear no other clothing.

Diet. The diet of the Arabs consists everywhere of flour and butter, variously made ready. Unleavened paste of flour and water, baked in ashes of camel's dung, and mixed up afterwards with a little butter, and thoroughly kneaded, is served up in a bowl of wood and leather. Flour and sour camel's milk, made into a paste and boiled (*thé ayesh*), is the daily and universal dish of the Aenezes. Bread baked in cakes is used at breakfast. Bread, butter, and dates, are also mixed together into a paste. *Burgout*, the common dish of the Syrian Arabs, is wheat boiled with some leaves, and then dried in the sun; it is preserved for a year, and served up with butter and oil. The Arabs never indulge in luxuries, except on a festival, or the arrival of some stranger; and the richest scheik would think it a shame to order his wife to dress any rare dish merely to please his palate. For a guest of distinction a kid or lamb is prepared, and for one of less consideration coffee or bread with melted butter. In Hedjaz, or the hilly district of Arabia near the Red Sea, the usual dish is Indian rice, mixed with lentils, and without any bread; and in the districts where the date grows it forms the chief sustenance of the inhabitants. In Nedjed, Hedjaz, and Yemen, the Arabs use butter to excess. They frequently swallow a whole cupful of butter before breakfast, and all their food swims in butter. The constant exercise and motion to which they are accustomed so strengthens their powers of digestion, that they can endure without injury the extremes of excess and want. They can live for months on the smallest allowance, or devour at a sitting the flesh of half a lamb. Butter is made from the milk of sheep and goats; but never, except in cases of necessity, from that of camels. Among many of the Arab tribes it is considered shameful to sell any butter, or among the Bedouins near Mecca to sell milk; yet the Beni Koreish, one of the most noble of the Arabian tribes, freely supply the inhabitants of Mecca with milk.

Hospitality. Hospitality, the virtue of rude nations, is practised among all the Arab tribes, and no violation of its duties was ever known. When a stranger alights at the tent, the host, or in his absence the wife or daughter, spreads a carpet for him and prepares the hospitable meal. If he remains any time his aid is expected in the domestic business of the tent, in fetching water, milking the camel, or feeding the horse. But he may neglect these duties and still remain, though he will be censured for ingratitude; or he may go to another tent, where he will receive a hearty welcome; and every third or fourth day may change his residence, and be comfortably entertained during his stay, however long it may be. The greatest insult that can be offered to an Arab, is to tell him that he does not treat his guests well. Among some tribes women never eat or drink coffee in the presence of a man; and in this case some male relation, in the absence of the host, does the duties of hospitality. In the plain of Hauran, southward of Damascus, the wives and daughters of the Arabs may drink coffee with the strangers upon their arrival; and in the mountainous districts south of Mecca, towards Yemen, women are allowed, in the absence of their husbands, to entertain a guest, and to sit up with him.

Law of marriage. The Arabs are not so dissolute in their morals as most of the nations in the East. They are generally content with one wife: instances of conjugal infidelity are not common, and public prostitution is not seen in their camps. Yet they are far from being duly impressed with the sacred tie of marriage, which may be at any time dissolved at the pleasure of the husband; and this facility of divorce relaxes morality, though, to some extent, the manners correct the laws. A Bedouin, aware that a divorce is always in his power, contracts a temporary marriage of a few weeks; and it is not uncommon for a

man, before he has attained the age of 40 or 45, to have had 50 wives. The wife also, if she is ill used, may fly for refuge to her father's tent, whence she cannot be reclaimed by her husband. Yet among the Bedouins many instances are found of conjugal fidelity and love. This rash dissolution of the marriage union is frequently fatal to the peace of one or of both parties. In 1815, Burckhardt mentions that a Bedouin of the Syrian desert, who had divorced his wife, and who was present at her second marriage, shot himself in a fit of distraction, the moment he saw the new husband enter the marriage chamber. The Wahaby ruler Saoud exerted all his authority to prevent the frequent divorces of the Arabs, by disgracing at court, or otherwise punishing, any man who either divorced his wife or used the expression *Aley et talak*, "I shall divorce," which, according to the Arab law or custom, cannot be revoked. Polygamy is permitted, but is not common, among the Arabs, owing chiefly to their poverty. The richer scheiks, however, indulge in a plurality of wives. The marriage ceremony among the Aenezes and most of the Arab tribes is extremely simple. The lover generally commences, through a common friend, a negotiation with the father of the girl; and if she is pleased, the friend, holding the father's hand, says, "You declare that you give your daughter as wife to ———;" to which the father assenting, the bridegroom comes on the marriage day with a lamb in his arms to the tent of his betrothed, and by cutting its throat before witnesses he completes the marriage ceremony. After the usual rejoicings the bridegroom retires after sunset to a tent at a distance from the camp, while the bride, in her maiden timidity, runs from tent to tent, struggling, kicking, and even biting those who attempt to conduct her to the bridegroom's chamber.

Rite of circumcision.

The rite of circumcision is still practised among the Arabs, and is the occasion of a great festival. All the boys are generally circumcised on the same day. Each man of the encampment kills at least one sheep in honour of his son, and the whole tribe feast on this abundant cheer. The men exhibit equestrian exercises and warlike evolutions; while the young women join in the national airs, and sometimes removing their veils, allow their lovers a hasty glance of their beauty as they pass. There are, besides, the festivals of Ramadhan and of the sacrifice of Arafat, where the same exercises are exhibited.

Mechanical arts, literature, music.

The Arabs are no great proficients in arts or industry, their only artists being a few blacksmiths to shoe the horses, and saddlers for the leather work. The arts of tanning and weaving are practised, the first by the men, the latter by the women. Of reading and writing all the Bedouins throughout Arabia are equally ignorant. The Wahaby chiefs were at pains to instruct them, and sent teachers among the different tribes, but with little effect. Nor have they made any progress in science or literature. In the first, their knowledge is confined to the names of the constellations and planets. Their literature consists in romantic tales of love and war, in which they delight; and the minstrel's strain frequently beguiles the evenings of an Arab encampment. Verses are recited or sung, and the voice is accompanied by a species of guitar, the only musical instrument which they possess. They have national airs also for female singers, which are chanted in choruses of six, eight, or ten voices, at some distance from the camp, in the solitude and silence of the desert. Many of the Arabian poets can neither read nor write, yet compose verses of exact measure, grammatically correct, and neither destitute of sentiment nor poetical beauty. Eloquence has from time immemorial been considered a necessary qualification of an Arab statesman: no scheik, however brave, can ever attain to influence among the Arabs without this talent. The language of Arabia is derived from the same original stock with the Hebrew, the Syriac, and the Chaldean tongues. Each tribe has its own peculiar dialect, but, by universal consent, the palm of elegance and purity has been, and still continues to be, assigned to the idiom of Mecca.

Moral character of the Bedouins.

The preceding details exhibit in no very favourable view the moral character of the Arabs; and the boasted virtues of the desert, when they are calmly estimated, seem to resolve into the observance of certain rules or prejudices, without which no community can exist, however rude or lawless. The thieves and outcasts of civilized society are linked together by certain ties of good faith, without which all concert would be impossible even for their own evil ends; and the honour that prevails among the Arabs seems not to be of a much higher quality. They are, according to the accounts of all travellers, immoderately fond of gain, which they do not scruple to procure by the basest means. "Lying, cheating, intriguing, and other vices arising from this source, are as prevalent in the desert as in any of the market-towns of Syria; and on the common occasions of buying and selling, where his dakheil (oath) is not required, the word of an Arab is not entitled to more credit than the oath of a broker in the bazaar of Aleppo." An Arab will defend his guest at the peril of his own life; he will submit with resignation to the most cruel reverses of fortune; and at Mecca, during the pilgrimage, the true Bedouin of the desert, unlike the other pilgrims, disdains to ask alms, and always lives by his own industry, however precarious or humble. On the other hand, in pursuing the trade of rapine, he seems to be degraded, by his thievish, cruel, and treacherous habits, to the lowest rank of barbarism. In their familiar conversation the Arabs are free, sprightly, jocose, and decent. They are not reserved or silent, according to the report of some travellers, except perhaps in their journeys through the desert, where much speaking excites thirst, and parches the mouth. In their tents they are indolent, all that they do being to feed the horse, or milk the camels in the evening. The herds and flocks are committed to the care of a shepherd hired for the purpose; and the husband goes out to hunt with his hawk, or to amuse himself in any other manner that pleases him; while the wife and daughters are engaged in the household cares, in grinding the wheat with the hand-mill or pounding it in the mortar, in kneading and baking the bread, making butter, fetching water, working at the loom, or mending the tent-covering. They are patterns of industry, yet they are not allowed to eat with the men, and only partake in their own apartments (the *meharrem*) of what they leave. If a lamb is killed, they seldom taste, except some of the worst parts, which the men are not able to eat. This degradation of the women is common to the Arabs with other Asiatic nations, and is a true feature of oriental barbarism.

Diseases.

The small-pox continues to make serious ravages among the Bedouins, and to depopulate whole encampments. Inoculation is resorted to with benefit, and the practice of vaccination has extended over Syria. Obstructions and indurations of the stomach, occasioned by the use of camel's milk, are common; but these complaints are alleviated by the purging qualities of the brackish water of the desert: also fevers, both intermittent and inflammatory; and the burning with a hot iron is here, as in the former case, the approved cure. Ophthalmic disorders are frequent, and leprosy, which is hereditary in families, and cannot be eradicated. It commences with white spots, as large as the hand, which appear on various parts of the

Arabia.

body, without rising above the skin. If the white spots appear on the cheek, the beard commonly falls off: the unfortunate sufferer is held in universal abhorrence. The toothache is unknown among the Arabs, who have all the most beautiful teeth.

Towns.

The chief towns of Arabia are situated either on the coast of the Red Sea, or in the range of mountains which runs parallel to its shores. They are, Medina, with Yembo its sea-port; farther south, between 200 and 300 miles, Mecca, with Djidda its sea-port; Tayf, east of Mecca; still farther south among the mountains, Sada, Sanaa, and on the coast of the Red Sea, Gonfode, Loheia, Hodeida, and Mocha; Derayeh is in the interior, and Mascat on the coast of the Persian Gulf. The population of the towns consists chiefly of foreign traders, who follow the customs of the place, but seldom imbibe the national spirit. Hence they form an entirely different class from the Bedouin Arabs. They have their faults without their virtues, are dissolute in their manners, and addicted to the grossest vices. The commerce and religion of Arabia concur to bring together in the towns a mixed population from the most remote parts of the world.

Commerce.

Arabia has few manufactures, for a supply of which it is therefore dependent on its foreign trade. From its central position, however, and its contiguity to the shores of the Red Sea, in former times the only navigable communication between Asia and Europe, it has always been a great entrepôt for the commodities of other countries. In the ancient world it was the medium of intercourse between India and Europe, and still continues to enjoy a portion of this commerce.

The sea-port of Djidda, on the Red Sea, seems to be the great emporium of the Arabian trade. Thither resort the annual fleets from Calcutta, Surat, and Bombay, about the beginning of May. They bring piece goods, Cashmere shawls, cocoa-nuts, rice, sugar, drugs of all sorts; small articles of Indian manufacture, such as china-ware, costly collections of which are often displayed by the rich inhabitants; hardware, pipes, beads, wooden spoons, glass beads, knives, rosaries, mirrors, cards, &c. See DJIDDA.

In Arabia, as in most other eastern countries where property is not protected, capital is slowly accumulated, and is in general far from abundant. The rate of profit is consequently high, amounting to 30, 40, or even to 50 per cent. No money can be lent out at interest as in Europe, it being contrary to the law of the Koran, and no one besides having confidence in another. There is no monied interest in Arabia. There are no stocks of any description, or public funds, in which money can be invested; and every capitalist is therefore engaged in trade, from which he never can withdraw to live on his money as in Europe. Credit is with difficulty obtained, and trade is carried on by means of barter or by sales for cash. Hence no Arabian merchant can contract debts which he is unable to pay; and there are consequently no mercantile failures in Arabia as in Europe.

The utmost profligacy of manners prevails in all the Arabian towns, as indeed in all Mahometan countries; and the holy temple, the very sanctuary of the Mahometan religion, is daily profaned by the grossest depravities, to which no shame is attached. The young of all classes are encouraged in those immoralities by the old; and even parents connive at the disgrace of their children, and profit by their iniquities. From such vices the encampments of the Bedouin Arabs are alone said to be exempt.

Later discoveries.

Between 1824 and 1827, and again in 1833 and 1834, Mahommed Ali, the late Pasha of Egypt, sent his armies across the great chains of Hedjaz and Yemen with a view to subjugation the fierce highlanders of Assyr. Among his staff-officers were several French gentlemen of scientific attainments, among whom Mr Chedufeau, who was chief of the medical department, occupied the principal place. To the zeal of this gentleman we owe much valuable information concerning the geography and the inhabitants of a large tract which was, until then, only known by hearsay. This tract occupies the eastern slopes of the centre of the Hedjaz-Yemen chain, and extends from Tayef, or about north latitude 21° in the north, to the 18th northern parallel in the south, and east as far as about east longitude 45°, no astronomical computations having been made. The country is very mountainous, the slope being eastward, and watered by many streams which form several large and well populated wadis. The principal are Wadi Subey and Wadi Zahran, east and south of Tayef, and farther south, Wadi Shamram and Wadi Zebran, which is the upper portion of Wadi Bisheh, the most extensive and best cultivated of them all. El Assyr proper occupies the south-west. Far in the east is Wadi Dowasir, and in the south, the fine valley Wadi Nedjran, the inhabitants of which are said to be the handsomest men in Arabia, and in the past century raised their country to much political importance among the petty Arab states. This tribe possesses large herds, and many excellent horses, which are highly esteemed at Sana. The united streams of the northern portion of this extensive tract form the River Tarabah, and those of the south the River Bisheh, both carrying a considerable volume of water, and flowing east, much beyond the limits of the Egyptian expedition in that direction. Between these two river systems there is the Wadi Raniah, which is watered by a goodly stream flowing into Lake Waradah. Great water-courses having been denied to Arabia, notwithstanding Ptolemy's statement of five (large and permanent) rivers, the question naturally arose, "where do these rivers of Assyr, which receive the whole volume of water which descends from the eastern slopes of a chain extending at least over three degrees of latitude, ultimately flow to?" According to the Arabs questioned by the French officers, they discharge themselves into a large lake, Salomeh, which appears to lie in the latitude of Mecca, and about east longitude 45°. The announcement of a large inland lake in the arid interior of Arabia, was at first startling, but it is supported by the statements of Arabic geographers, whose *Feledj-el-Afladj* in Yemamah seems to occupy the environs of this hitherto unvisited lake. They speak in high terms of the numerous water-courses of Yemamah, many districts of which are called *Feledj*, literally a canal of irrigation, of which *afladj* is the plural. But here a similar question rises as above,—"where does the surplus water of Lake Salomeh flow to?" Undoubtedly eastward, whence it is but natural to assume that the great river El Aftan, the lower course of which has been traced underground in Bahrein, is but a continuation of the river flowing into Lake Salomeh, which in its turn presents all the features of the upper course of a large river, as it is the confluent of a great number of mountain streams carrying a considerable and permanent volume of water, and meandering through a large extent of country.

Mareb.

The high table-land on which lies the city of Sana, and which is overtopped by many lofty peaks, slopes rapidly down in the east towards the plains of El Djof-el-Yemen. Many *seils* or torrents precipitate themselves from its acclivities, forming narrow and steep passes through which the traveller descends into the burning lowland. An old tradition, supported by the evidence of Greek and Arabic geographers, and confirmed by the statements of intelligent natives, identifies Mareb, the capital of that district, with the ancient Saba or Sheba, whose queen once visited Solomon. All Arab writers agree that Mareb, although an inconsiderable place at the various periods in which they wrote, was still surrounded by vast ruins, the remnants of its former grandeur. It was said, that with a view to procuring a constant supply of water for the irrigation of their wadi, the inhabitants, in time immemorial, had constructed an immense stone wall across their valley, but above the town. The water flowing down from the high mountains in the west, was thus collected beyond the dike, where it expanded into a large and deep lake. The dike, however, gave way, and an irresistible flood not only destroyed the town below it, but also the cultivated fields in the valley; and the inhabitants being unable to raise the wall up again, the whole extensive district was changed into a desert. When Niebuhr was at Sana, he gathered much valuable information concerning those water-works, and the destruction of that vene-

Arabia.

rable metropolis of the Himyaritic kingdom, but neither he nor any other European succeeded in penetrating to that classic spot, till in 1843 an enterprising young Frenchman, Thomas Joseph Arnaud, accomplished the task at the imminent risk of his life. His description tallies with and confirms the accounts of Niebuhr and others. Mareb, the splendid *Mariaba metropolis* of Ptolemy. is now a miserable village surrounded by a brick wall, but the environs are covered with ruins, testifying its past greatness, and marking the area it once covered. The ancient residence of the queen of Sheba, or perhaps that central portion of it which formed the city properly speaking, was of a circular shape, about a mile in diameter, and encompassed by a massive wall of free-stone. Within and without its ruined precincts, lie scattered about innumerable fragments of solid buildings, large square stones, portions of brick masonry, friezes, and other house ornaments, and even whole columns hewn out of a single block of the hardest limestone. West of the ancient town are the ruins. They are the extensive remains of the outer wall of a palace which the inhabitants call Haram Bilkis, "the palace of Bilkis," in memory of the Sabæan or Himyaritic queen Bilkis, who is not only said to have been the founder of that royal residence, but is also identified with the queen of Sheba of Scriptural renown. A portion, about one fourth, of the wall is still standing, and covered with Himyaritic inscriptions, of which Arnaud copied as many as circumstances would allow him. Other inscriptions are found on many of the large blocks which lie scattered about.

The great dike.

The ruins of the famous dike are to the east of the town. There the bed of the Seil Dana, a torrent, dry in the summer, but swelling into a deep and impetuous river in the rainy season, is hemmed in by two mountains, forming a gate through which the flood rushes into the plain. Each of these mountains is called Balak. They are 600 paces asunder, and between them the ruins of the stone dike occupy an area 300 paces long, between the bases of the two Balaks, and 175 paces wide in the direction of the current. The portions leaning against the projecting foot of the mountains are still in such a state of preservation as to allow the examiner to guess their destination. There are many gates or openings in the wall through which the water was allowed to escape into the plain below; they are in perfect preservation, and constructed at different levels, so as to secure a regular supply. As far as the traveller's eye could reach from the adjoining hill, the bed of the Dana and the plain on either side was strewn over with fragments of masonry, giving the whole the appearance of a vast cemetery covered with tombstones. Previous to the breaking of the dike, the wadi was fertile and cultivated for a distance of seven journeys, but it is now a sandy desert through which, in the rainy season, the torrent of the Dana rushes on towards the interior. It seems to be the upper course of the river which waters the Wadi Maifah, which opens towards the sea below Nakab-el-Hadjar, and west of Hisan Ghorab, both renowned for the Himyaritic inscriptions which have been discovered there.

El Yafa.

The tract bordered in the north by El Djof, and in the west by the southernmost portion of the highlands of Yemen, and the Tehama of Aden, near Ras Seilan, in the east by the Wadi Maifah, and in the south by the Indian Ocean, is called El Yafa. It is subdivided into several smaller districts. Along the sea stretches a tehama. Above it rises a section of the great southern mountain chain with peaks attaining an elevation of above 5000 feet, such as Djebel Amzuk and Djebel Hammari. North of this chain the country is a high table-land untrodden by Europeans. The central portion of El Yafa is bisected by a considerable river coming from Damar, in Yemen, and which, after having washed the principal town, Yafa, breaks through the high range and loses itself in the sand of the tehama. But the river Meidam, on the frontiers of Yemen, is a permanent stream—a rare thing in Arabia—and in all seasons of the year reaches the sea in the Bay of Tuwayi, near Aden. The high plateau of Yafa is barren, but the valleys and slopes of the mountainous portion are fertile, well cultivated, and well inhabited. Coffee is cultivated in Yafa, but only in its western parts.

Hadhramaut.

Hadhramaut was a *terra incognita* until a very recent date. The Europeans had heard of a Wadi Doan, praised by the Arabs for its fertility, its numerous well-built towns, and its flourishing commerce. But its position remained uncertain. Niebuhr, following the vague statements of some natives of Hadhramaut, who probably intended to deceive him with a view to deter him from proceeding thither, placed it in the far north-east of that province, at many hundred miles from the place where it was subsequently discovered; and all later geographers blindly copied the mistake, although Seetzen, who had drawn his information from more credible sources, determined its position with approximative accuracy as early as the beginning of this century. The lovers of Arabic geography and antiquities, nevertheless, kept their eyes on that celebrated wadi, as it was expected that monuments and other traces of the ancient Himyaritic power would be found there. At last the late Lieutenant Wellsted discovered Himyaritic inscriptions at Hisan Ghorab, near Ras Kell or Dog Cape, and others at Nakab-el-Hadjar, in the Wadi Maifah, which he had ventured to visit. His account excited unusual interest in England and on the Continent, and several distinguished scholars devoted their energies towards the deciphering of these time-honoured mysterious characters. Moved by such and similar considerations, a man now entered the arena of discovery who already takes rank among the most eminent explorers of Arabia, although his sojourn in the unknown land was shortened by the jealousy of fanatic Bedouins, and the account of his researches has not yet been placed before the public.

The Baron von Wrede.

In the year 1843, the same in which the Frenchman Arnaud discovered the ruins of Saba, the Baron von Wrede, a German gentleman, who, during a long sojourn in Syria, Egypt, and Arabia, had made himself thoroughly acquainted with the Arabic language and oriental manners, started from Cairo with a firm determination to explore the Wadi Doan and other parts of Hadhramaut. He succeeded, though only partially, but still at the risk of his life. Travelling in the disguise of an Egyptian, on a pilgrimage to the tomb of the prophet Hud, he passed as such, in the eyes of the natives, for a considerable time. Suspicion, however, arose, and he was ultimately discovered to be a European and a Christian. He was thrown into prison, and kept there during three days, hourly expecting death; but the Sultan of Grein having succeeded in quieting the fanatical Bedouins, who cried for his blood, granted him life and liberty on condition of his leaving the country without delay. He did so under the safeguard of the sultan, but deprived of his wardrobe, his money, his instruments, and many, but fortunately not all, of his papers and drawings. After his return to Cairo, he wrote an account of his researches and adventures, from which the following outlines of Hadhramaut are extracted.

Name.

"Hadhramaut" is said to mean "the country of death," either in allusion to its pathless deserts, or to the curse of the prophet Hud, who, according to an old Arabic legend recorded in the Koran (chap. vii., El Ahraf, and chap. xlvi., El Akhaf), punished the unbelieving and blasphemous tribe of Ad, who dwelt in that part of Arabia, by sending a fiery wind into the country, which reduced the fertile fields to burning deserts, and destroyed its inhabitants. But this etymology is questionable. In its larger meaning, Hadhramaut comprehends the immense tract between Yafa and Oman, which is separated from the heart of the peninsula by the desert El Ahkaf. The traveller only visited the south-western portion of it, namely, the Wadi Doan, its environs, and the tract between it and the sea.

Mountains.

This province of Arabia, like all others bordering on the sea, consists of three distinct physical portions, viz., *firstly*, a narrow tehama intersected in some places, as at Ras Farlak, by spurs of the inland mountains advancing upon the ocean, and forming lofty projecting capes; *secondly*, a serrated mountain belt rising in terraces over the low land; and, *thirdly*, an inland plateau of great elevation overtowered here and there by lofty peaks; and, in other places, rent asunder by deep fissures which gradually expand into cultivated wadis and wide luxuriant valleys, watered by streams which, according to the season, are sometimes ripling rivulets, at others impetuous torrents. The mountain belt, an almost alpine chain, stretches in one uninterrupted line from Yemen to the borders of Oman, where it diminishes in height; but no general name having ever been applied to it, that of the "Himyaritic chain" may be here suggested as not quite inappropriate. Beyond, that is to the north of, the high plateau, there is a sudden steep de-

scent into the sandy deserts of El Ahkaf. Wrede estimated the average breadth of the Himyaritic chain at 25 German, or 100 geographical miles; and its length being upwards of 1800 geographical miles, it apparently ranks among the great mountain systems in the world. In fact, its length is one-half of that of the Cordilleras of the Andes, twice that of the Ural, thrice that of the Alps and the Caucasus, and it seems to occupy an area of nearly 200,000 square geographical miles. The highest peaks appear to attain an elevation of 10,000 feet.

From Makallah, which was Wrede's starting point, the *akabah*, which means "ascent," and is the general name in Arabia for the rising portion of mountains, was very steep, till the traveller arrived on the first terrace. There the acclivity was interrupted by a narrow barren plain, followed by another akabah, which, in its turn, led to another terrace, and so on in regular succession, till the high plateau was gained. Here the nights were severely cold. The basis of this tract is granite, with its usual superstrata, heaved up and broken into wild chaotic masses, by volcanic action, of which the traces are so frequent and so visibly evident, as to lead to the surmise, that there are still active volcanoes somewhere in the country, having the same common hearth with those which are still in activity in the islands, near the entrance of the Red Sea, and those which ceased to be so in Yemen. According to an Arabic legend, Yemen was separated from the opposite coast of Abyssinia by a tremendous earthquake, which caused the waters of the Indian Ocean to enter the Red Sea. Many thousands of people were drowned, and such were the lamentations of the survivors, that the new channel was called Babelmandeb, or the gate of tears. Primitive limestone forms chains of considerable length and elevation, as, for instance, along the wadi Maifah, the summits of which range between 4000 and 6000 feet in height. Jura limestone occupies large tracts, whence caverns with subterranean streams are frequent. Wrede entered one which was very capacious and deep, the vaults hung with beautiful stalactites, and the whole cavern resounding from the noise of a powerful stream rushing unseen through the bowels of the rock. But the natives fearing to irritate the *ghuls* or evil spirits, with which their superstition peoples these caverns, would not allow him to penetrate to the deeper recesses. Hot springs are frequent, and there is such a number of fissures and caves through which sulphureous vapour escapes, and the sides of which are so thickly covered with the finest sulphur, as to warrant the supposition that a large and profitable trade with that article might be established here, if the natives would allow the access to strangers, and there were roads in the country. The most celebrated among the sulphur caves is the Bir Bahut, through which, according to the natives, the souls of the damned go down to hell, in contradistinction to the crater in the island of Djebel Teir, in the Red Sea, through which the devil is said to come up from hell, when he is about to do mischief in the world. Bir Bahut is most probably the *Fons Stygis* of Ptolemy. In many localities, the steep rocks encompassing the wadis are quite perforated by such caves; and as they offer cheap habitations, and are above the level of the highest floods which fill the glens after heavy showers, half savage tribes of Bedouins have turned them into permanent dwelling-places for their families. As the traveller passed by, scores of swarthy children suddenly issued from the holes like rabbits from their burrows, to have a peep at the strangers. During the frequent absence of the inhabitants, the caves are watched by a race of very fierce dogs. The habits of the people having remained the same during thousands of years, it is but reasonable to believe that in ancient times also there was a troglodytic population in this part of Arabia, and that the statements, to that effect, of Ptolemy and other Greek geographers, are quite correct.

Volcanoes, caverns, and hot springs.

Troglodytæ.

Origin of wadis.

The Baron von Wrede compares the aspect of the country with its countless wadis, as seen from above, to a gigantic leaf divided into innumerable compartments by the network of its veins, the principal of which being the Wadi Doan, which bisects the tract from one end to the other. The wadis have their origin on either side of the crests of the hills, and on the high plateaux of those low ridges which interrupt the level. Their first beginning is an almost imperceptible rill, or a mere fissure in the sloping rock, which gradually widens, owing to the agency of water, and assumes the aspect of a narrow glen encompassed by two walls of perpendicular rock. If there are springs in its upper portion, there will be a permanent stream; if there is no water but that descending in sudden and heavy showers, in the rainy season, the stream will be transient; but in either case, the volume of water rushing down these gaps in the rainy months surpasses belief, and its velocity is so great, its rush so sudden and irresistible, that lofty and solid rocks, undermined at their base, will crumble into huge fragments, which the roaring flood carries downward, till, expanding itself over a wider space, it loses the power of its first impetus. In consequence of this never-ceasing activity of nature, the detritus and rubbish along the base of the rock-walls increases in width and height, in proportion as the wadi becomes wider; and it is on these slopes that the Arab begins the work of cultivation. In many localities, the upper portions of the wadis lie in deep gaps produced by volcanic action, while among the craggy rocks in the mountains between the table-land and the tehama, they do not differ from glens and valleys in other mountainous countries of a similar geological character.

Wadi Doan.

The head of the Wadi Doan is a deep gap in the centre of the barren table-land, upwards of sixty geographical miles north-west by north from Makallah. Nothing announces its approach; its palms, its houses, its turreted castles, its crystal stream and verdant plantations, lying, as it were, hidden in the bowels of the earth invisible to man, like the bottom of a precipice, till his eye merges over the upper edge, when the scene below bursts upon him like enchantment. A narrow, steep, and very dangerous path leads from the edge down into the glen, which is about 300 paces asunder, with a narrow belt of cultivated slopes at the base of the rock-walls. But the glen gradually widens, the rocks on either side losing their steepness and craggy aspect, till it expands into a fertile valley, measuring from 20 to 25 geographical miles across in its widest part. The direction of the Wadi Doan, the name being applied to the whole length of the valley, is at first north-west, then north-east, east, south-east, and south, when it issues upon the Tehama and Sihut, about a hundred geographical miles east of Makallah. Its whole length may be computed at 120 geographical miles, but only its upper course is known. Its head is the Wadi Minua, with a branch, the Wadi Nebbi; the next section is Wadi Doan, properly speaking; and the other parts are successively called Wadi Hadjarin, Wadi Kasr, and Wadi Missileh. This valley has many branches, most of which slope down from the high table-land to the south and west of it. Wadi Doan is studded with towns and villages from its very beginning, and the slopes, as well as the wider level tracts between the encompassing hills, are surprisingly well peopled and cultivated, the fields, or rather gardens, bearing rich crops of durra and other corn, dates, bananas, melons, cucumbers, indigo, and a variety of other vegetable products, of which considerable quantities are exported. The stream is not permanent, at least not in its upper course, where particular care is bestowed upon irrigation. During the sojourn of the Baron von Wrede at Khoreibeh, one of those awful thunderstorms broke out which have been alluded to above. It was still at a distance, and the clouds lowering over the town did as yet but threaten to discharge themselves, but they had evidently burst further up, when piercing cries of "The flood! the flood!" alarmed the inhabitants. Men, women, and children, were now seen running in haste and trepidation to gain their houses, which stand on the rising slope, when suddenly a tremendous body of water came roaring down the dry bed of the river, sweeping everything moveable before it, and threatening to annihilate the whole town. Cloud now burst upon cloud, and every voice and sound was drowned in the rush of the waters and the never-ceasing peals of thunder, while the narrow glen was shrouded in night, lit up every now and then by the transient blaze of the firmament. An hour thus passed away, when the sun again darted from a cloudless sky, and the flood was gone without causing any destruction; but all the canals of irrigation running parallel with the stream, and the numerous reservoirs and tanks, were overflowing with that precious gift of nature, without a constant supply of which, the inhabitants would be obliged to abandon this picturesque valley.

Bahr-es-Saffi.

At the foot of the Akabah, leading from the table-land to the desert El Ahkaf, there is a desolate district very much dreaded by the natives on account of a very singular phenomenon. It

Arabia.

appears that in the adjacent portion of El Ahkaf, there is a great number of large, unfathomable pits or gulfs filled with quicksand, or rather a white, grayish dust, soft to the touch, and different in colour and substance from the yellowish and reddish sand of the desert. Whatever falls into such a pit disappears instantly. The gulf visited and examined by Wrede, was about a mile in diameter, and clearly distinguishable from above owing to its colour, by which its surface was set off against the darker desert. The Baron having been unable to persuade his Bedouin guides to follow him to "the mysterious abode of ghuls," cautiously approached the edge of the gulf provided with a plummet, weighing a kilogramm, and a line 60 fathoms long. Having thrown the lead as far over the edge as possible, it disappeared the moment it touched the surface, and continuing to sink, rapidly drew the line after it, till in a few minutes both plummet and line had disappeared, the latter having slipped through his fingers, which prevented him from drawing it back and making a second attempt. The Baron does not venture upon an explanation of this phenomenon, but there seems little doubt that these gulfs are extinct craters filled with some attenuated volcanic substance of a whitish colour, and similar to that which produces the far-seen white streaks on the volcano Djebel Teir in the Red Sea. The sand gulfs extend over a large district which is called Bahr-es-Saffi, or the Sea of Saffi, after a certain king, who, as the legend goes, ventured to cross this tract with his army, while contemplating the conquest of Hadhramaut, but was swallowed up by the sand-gulfs, together with the last of his men. The story reminds us of the fate of a portion of the army of Ælius Gallus. The only difficulty is the circumstance that this white dust remains on a stationary level, a little lower than that of the desert, and does not mix with the yellow sand of the common desert. As to the rest, large and deep volcanic craters hollowed out in the level plains of table-lands, are by no means of rare occurrence. Those in the Auvergne, in France, and in the Eifel, in Germany, being filled with water, are lakes in every sense of the word (Maare), but as there is no superabundance of water in the desert El Ahkaf, sand, of which there is more than sufficient, seems to have taken its place.

The whole Ahkaf appears to have once been the bottom of a great fresh-water lake, perhaps raised to a higher level by one of those tremendous volcanic commotions which have been so active in the formation of the surface of Arabia. Supposing, therefore, that the gulfs are craters communicating with great caverns in the earth, we presume that the water escaped through them while the rocky bottom of the lake was in progress of rising. The craters were subsequently filled up with the lighter particles of the desert sand, which, although of a general yellow colour, does not appear to be of a homogeneous nature, and in proportion as the sand or dust sinks into the earth, the water at the bottom carries it off into the bowels of the earth. Admitting this, the sucking qualities of the sand, and the equal level of its surface, to which local causes may also contribute, are easily accounted for. Admitting further the compound nature of the desert sand, it is evident that, once changed into quicksand by the action of water, the yellow particles, being derived from ferruginous sandstone, and consequently heavier, must necessarily sink through the lighter whitish dust; whence the uniform white aspect of these remarkable sand gulfs. The powerful springs in the wadis El Hajar, &c., which all burst forth on the south side of the plateau, and on a level considerably lower than that of the Ahkaf; the subterraneous stream in the Bir Ba Rahut; and the hot sulphureous spring near Sah Hud on the coast, are all, in the opinion of Wrede, connected with the mysteries of Bahr-es-Saffi.

Products.

The abundance of sulphur has been mentioned. The brownish or reddish colour of the level portions of the high tableland originates undoubtedly from the presence of an abundance of oxide of iron in the rock which has contributed to its formation. Traces of gold have been found in the south. There are numerous quarries yielding an excellent stone for building purposes, and there is no want of materials for burning good lime and making cement. The vegetable products are the same as in the rest of Arabia, a few species excepted. Indigo is extensively cultivated, but coffee not at all. The slopes of the Himyaritic range are covered with magnificent forests; the valleys are clothed with shady groves, and springs issuing from every fissure, give rise to a countless number of rivulets and rivers swarming with small fish. But the tableland, and in general all the plains, whether high or low, are barren and miserable. There are no cows in Hadhramaut, except a few near Makallah, which, however, are of the Indian species, with a hump on their back, like those in Yemen. Horses are very rare. The common beasts of burden are the ass and the camel, the former vying in beauty and usefulness with those of Bahrein and Oman, and the latter being equal to those in other parts of Arabia. The common belief that the camel is only serviceable in sandy plains, is not at all based on facts. On the contrary, the same camel which patiently wades through the burning sand of the tehama, climbs up the most rugged and dangerous mountain paths with a sure footing and a steady step. Sheep, and still more so goats, are very numerous, the latter yielding excellent milk. There is no want of antelopes, hares, and other game, and there are few beasts of prey.

Inhabitants, towns, houses.

Here, as elsewhere in Arabia, the natives are divided into two very distinct classes—the settled inhabitants living in towns and villages, and the wandering Bedouin. The former are nearly as civilized as in Yemen, less corrupted, but infinitely more fanatical. The prophet Hud is held in great veneration among them, and swarms of pilgrims annually visit the tomb of that mythological person, which stands in the lower part of the Wadi Doan. They call Hadhramaut a land sanctified by that holy prophet, undefiled by the foot of either Jew or Christian, and the unconquerable asylum of the true doctrine of Mahomet. The number of well-built towns, which are all fortified, is surprising, and the Wadi Doan is quite studded with them, presenting, in several localities, the curious sight of twin towns, each a separate town with its own walls and towers, and its own sheik, or even sultan, and only separated from the other by the narrow stream which waters the valley. The principal towns in the Wadi Doan are:—Grein and Khuairah, twin towns, with a combined population of 9000; Zhaher and Matrah, the same; Gelbuhn, 4000; Rashid and Arsameh, each 5000; Rhudaish and Rihab, each 6000. In Wadi Hadjarin, a branch of Wadi Doan, Meshed Ali (once a large place), and Es Seif, twin towns, total population, 6000; Gahdun and Sava, each 6000; Haurah, 8000. In other localities, Ghoraf, Borr, Tierbi, Agnab, Tsah, and Makallah, each about 6000; Terise, 10,000; Shibam and Terim, each 20,000 inhabitants. Some of these towns are governed by a sultan whose authority extends over a more or less extensive tract; others are governed by sheiks who are the lieutenants of the sultan, at least nominally. But they all, sultans, sheiks and townspeople, bow to the supreme rule of the Bedouins. The houses are mostly solid and lofty buildings, constructed with freestone, and so compactly assembled, that the towns occupy a comparatively small area. There is a brisk trade going on with native products and foreign importations, among which English manufactured goods, German cutlery, and Bohemian glass, as well as various Indian commodities, form no inconsiderable item. In this unknown part of Arabia, Wrede found the house of a sheik furnished with European chairs and tables manufactured at Bombay; and the owner, who had been in India, not only spoke English well, but had a small library in which Sir Walter Scott's "Life of Napoleon" was prominent. At a dinner given to the traveller by the sultan of Khoreibeh, sherbet was served up in an earthen vessel of Staffordshire manufacture, of a description, however, such as is not used for lemonade in Europe. The townspeople are very fond of going abroad, as traders, sailors, &c., some to the seaports in India, others to those along the Red Sea, and others to Egypt, especially Cairo, where they are numerous, and known under the name of Hadhrami or Doani.

Bedouins.

The Bedouins in Hadhramaut are very numerous, divided into a great number of clans, and exhibiting peculiarities of character and habits which distinguish them from their brethren in other parts. They are a fine, strong, and athletic race of people, equally capable of supporting the stifling heat of the tehamas, and, though half naked, the intense cold on the uplands. The laws of hospitality are so far respected by them, that a stranger once received among them, becomes, as it were, a sacred person whom they will protect and defend at the risk of their own lives. Clan feuds are frequent among them, arising generally from murder and the like causes of violence, which the kinsmen of the murdered are bound to avenge by killing

either the murderer himself, or one of his family; and, when none of these are to be found, one of his clan. This goes on by rotation, each party having its turn of taking revenge, till at last whole tribes rise against each other in hereditary feuds. Many tribes are confederated, so that not only their own people, but also strangers standing under their protection, are safe in each other's territory. Even a man against whom there is a cause of blood revenge, is safe from vengeance when under the protection of an ally of his persecutors. The Baron von Wrede having procured a protector, or *dakheil*, at Makallah, was well received by the man's clan, and on subsequent occasions found that the dakheil he obtained in the interior could, under all circumstances, be relied upon, although a considerable degree of firmness was always necessary on his part to support his protector's sense of duty against fear or temptation. The Bedouins profess to be Mahometans, but they care very little for a strict observation of the law of the prophet, pleading the still greater sanctity of the law of necessity, whence they will eat all sorts of unclean animals, such as snakes, lizards, and the like vermin, "because they are hungry, there is nothing else to be got, and the law of the prophet does not fill their bellies." Here, as well as in Yemen, there are many remnants of the ancient fire-worship, which was the prevailing creed in South Arabia previous to Mahomet; and the prophet Hud, who lived in an age so remote, and whose person is so completely mythologized that modern scholars have been tempted to identify him with Bacchus, is no less revered by those children of the desert than Mahomet himself. But the reformed creed of the Wahabys never penetrated into these mountains. The Bedouins of Hadhramaut are altogether the fiercest and rudest among all the wandering tribes of Arabia, and whatever is calculated to uphold and propagate that reckless and savage spirit, is more admired by them, and esteemed more worthy of imitation, than the precepts of a refined morality. A lad having deliberately shot his father, who wanted him to fetch some camels, and kicked him when meeting with disobedience, was not only not punished by the tribe, but applauded, and finally praised by his own dying parent, who, being in the act of taking revenge by shooting his son in his turn, suddenly dropped his gun, exclaiming—"No! let him live, he has acted like a man." The women of the Bedouins go about unveiled, and in the towns only married women hide part of their face, the young girls being allowed to exhibit their charms to the other sex without any other restraint but that of common decency. The Bedouins look upon the townspeople as a degenerated, cowardly, mercenary race, losing no opportunity of showing them their contempt; while, on the other hand, the settled, civilized Hadhrami speak of their wild brethren in the desert as a set of overbearing savages, and behave to them in a manner as the Byzantine Greeks did towards their conquerors, the Turks, cringing before their eyes, and cheating them behind their backs.

Language. The Arabic of Hadhramaut, especially that of the Bedouins, differs from that of Yemen, not only in pronunciation and accent, but also by the admixture of many non-Arabic words, which are, without doubt, remnants of the ancient Himyaritic. This latter language, or perhaps only a modified dialect of it, is still spoken in the interor of El Shehr or Mahra, and in all probability also in the eastern parts of Hadhramaut in the larger meaning of the word, but not along the sea-coast, where the modern Arabic prevails. The Baron von Wrede obtained a little vocabulary of Himyaritic words of the present vernacular tongue, among which the word "ofir," that is *red*, strikes the antiquarian at once, as being the key to the whereabouts of the Biblical "Ophir." For the Mahra people also call themselves the tribe of the *red* (ofir) country, and the same appellation they give to the Red Sea, which is but a translation of Erythrean Sea, which we are fully justified in supposing to be, in its turn, a translation of "Bahr Ofir." Other words, which are not found in the Arabic language, are:—*aïf*, bad; *diyah*, good; *fadhan*, hill; *gai*, *kin*, much; *kar*, house; *ebher*, well; *huf*, milk; *istaha*, sit down; *karhai*, small; *ket*, rope; *makedir*, durra; *rigau*, tall; *sami*, dead; *shikah*, near; *sheli*, very near; *salet*, oil; *sheiwat*, fine; *shiff*, hair; *tahrir*, antelope; *tahriz*, kill (him); *thama*, alive; *terab*, wood; *tobba*, great, powerful, &c.

Antiquities. The spirit of destructiveness which the Mahometan Arabs exhibited against whatever was not in accordance with, or left unmentioned in, the Koran, and their hatred of religious symbols, combined with an utter disregard of that historical learning which alone is calculated to keep alive, in the lapse of centuries, that feeling of piety towards the works of our forefathers, which is the real inexhaustible source of all love of antiquity, —these various combined causes have produced a sinister influence upon the monuments left by the kings and the nobles of Himyar. Yet some important remnants have been preserved, as shown by the researches of the travellers mentioned above; and the Baron von Wrede has not only added to the list, but leaves a fair prospect to future travellers of making still more important discoveries. At Khoreibeh he obtained a copy of an old Arabic MS., being a history of Hadhramaut from its earliest times, and containing a complete list of the Himyaritic kings from the founder of the kingdom down to Mahomet, corresponding with, and completing the list given by Abulfeda. In the Wadi Obneh, he copied a beautiful Himyaritic inscription of five lines, the characters of which seem to indicate Sabæan models; and he not only examined many substructures of modern buildings, which belong to a very early and primitive period, such as castles and houses of sheiks, but obtained positive information on the *Tulbet-el-moluk*, or the "tombs of the kings," in the lower part of the Wadi Doan, not far from Grein and the tomb of Hud. They are forty in number, each being a separate structure covered with Himyaritic inscriptions, and they are held in great veneration by the natives, although only a few even among their learned men know what they are. The Baron was prevented from visiting them by his arrest at Grein.

El Shehr or Mahra. The coast of this extensive province is now completely surveyed, but of the interior we know nothing. Much gum and frankincense, the latter of very ordinary quality, grows in the mountains along the coast, between Capes Ras Fartak in the west, and Ras Nus in the east. The tehamah is narrow, and in many places interrupted by spurs of the Himyaritic range projecting into the sea, as at Ras Fartak, the *Promontorium Syagrios* of the ancients, a bold rock rising 2500 feet above the Indian Ocean; and at Ras Shejer, which is still higher by 500 feet. The Himyaritic range lowers considerably as it advances north-east, some inconsiderable ridges of barren sand-hills being its extreme feelers towards the high mountains of Oman. West of Ras Nus is the fertile plain of Dhafar, where the cultivation of indigo occupies many hands. Dhafar, its former seaport, exists no longer; it was the seat of the bishops of Hadhramaut, when the Christian religion prevailed here in the period preceding that of Mahomet, and after they had left their former residence at Nagra, or Nagrane. East of the same cape Mr Cruttenden and party discovered the large, fertile, and well peopled Wadi Rekob, with a running stream dried up in its lower course, but which must be a powerful river in the rainy season, as testified by enormous blocks of rock carried down by the torrent from the mountains farther inland. The inhabitants are a remarkably handsome and well-disposed tribe, the women being the handsomest in Arabia, according to the statement of the British officers, their visitors. They have large herds of goats and sheep, and seem to lead a happy life as shepherds and agriculturists. In the upper portion of the Wadi Rekob lies a thriving town, Djezzar, which, however, the party had no time to visit. The inhabitants of the towns and villages along the sea, are addicted to piracy, for which they have been frequently punished by the British men-of-war; and they all pursue the capture of sharks, with which the sea swarms, and the fins of which, when salted and dried, are not only eaten by the Arabs, but yield an important article of export to the Indian ports and China, where they are considered great dainties.

Oman. Oman, the north-eastern peninsular projection of South Arabia, is physically hardly connected with the Arabian continent, from which its mountainous territory is separated by the eastern El Ahkaf. Its coast and seaports were known to the Europeans at an early date. Its capital, Mascat, was conquered by the Portuguese in 1508, who kept possession of it till 1658, when the Arabs, taking the town, put the whole garrison to death, and established a native government under a prince of the ancient dynasty of the tribe of the Yaharibi-el-Azad. The country was subsequently conquered by the Persians, who were driven out in 1730, in their turn, by Ahmed Ibn Said, an adventurous chief, who claimed collateral descent from that

Arabia.

illustrious dynasty, and whose descendants still occupy the throne. The interior of Oman was first visited by the late Lieutenant Wellsted and his travelling companion, Lieutenant Whitelock, in 1835 and 1836; and although two years after them an enterprising French botanist, the late Aucher Eloi, made a trip into the inland district, the account of the British officers is still our main source of information. The north-eastern coast line against the narrow part of the Indian Ocean, opposite Beloochistan, is a serpentine curve 360 to 400 geographical miles long, extending from Cape Ras-el-Hadd, in the south-east, to Ras Musendom, in the north-west. The coast along the main of the Indian Ocean, in the south-east, is about 90 miles long; that along the Persian Gulf, in the north-west, about 150 miles; and the desert frontier, from sea to sea, in the south-west, about 300 geographical miles. A long range of mountains stretches from Ras-el-Hadd to Ras Musendom, almost parallel with the coast, and of which the central knob, the Djebel Akhdar, or Green Mountain, is the highest portion, rising to nearly 7000 feet. The height of Djebel Fellah and Djebel Hutah, in the south-east, is about 6000 feet; but the hills in the north are of less elevation. West of this range there is a barren plateau dotted with a great number of fertile and well-cultivated oases; the western edge of which forms another chain of mountains, less high than the main chain; and beyond this stretches the silent El Ahkaf. Beyond the desert, but where exactly we do not know, rises the Nedjed of El Yemamah, which is nearest to Oman in the north. The tract nearest to Ras-el-Hadd is called Djallan; west of it lies Oman proper, at the southern foot of Djebel Akhdar; west of Oman extends Dhorran, or the principal portion of the plateau, as far as the Persian Gulf, if the coast district is added to it. The tract extending north-west of Mascat, between the Indian Sea and the main range, is called Batra; it is intersected by numerous streams descending from that range; its soil is fertile, and well-cultivated, and its population may be called dense, as compared with the other provinces. The sea-shore is studded with towns and villages, but in the interior there is only one, but considerable town, namely Rostak, which was the residence of the reigning princes ere they took up their residence at Mascat. The southern portions of Oman are, on the contrary, very thinly populated, the soil being sandy; and as much may be said of the northern projection between the Persian Gulf and the Indian Ocean. The country produces wheat, maize, durra, and other grain, in great abundance; and besides the common fruit of Arabia, it yields indigo, cotton, sugar, and coffee. The latter article is not so good as the produce of Yemen, because not only less care is bestowed upon the plantations, but chiefly because its latitude is beyond the isotherm of the coffee-tree in Arabia and Africa, so that its growth would cease altogether, were it not for local causes. Irrigation is well understood: subterranean main conduits (feledj) four feet wide, with a running stream two feet deep, and from six to eight miles long, carry an abundance of water from the mountains into the drier plains. The camels and asses of Oman are justly celebrated. The breed of horses is excellent, but not numerous; the export of native and Nedjed horses from the port of Mascat, for the supply of the H.E.I.C.S. cavalry has of late much abated, the stock in the interior being almost exhausted. The same cause has affected the export of horses from El Katif, on the coast of Bahrein. The imam has several studs, the principal food being, next to barley, lucerne and dates. The cattle are of the Indian species, but although a large proportion of their food is said to consist of dried fish, the beef is tender and delicious to eat. The natives keep vast flocks of excellent sheep and goats; and there is an abundance of common fowl, but neither turkeys, guinea fowl, geese, nor ducks.

Divisions.

Inhabitants.

The relations between the settled inhabitants and the Bedouins are nearly the same as in Hadhramaut; the latter are a strong handsome race, and physically much superior to the tiny Bedouin of Nedjed. Their pursuits are pastoral and agricultural in the interior; but those who are near the sea are traders and mariners. The townspeople are much mixed with Persian and African blood.

Towns.

Mascat, the capital, counts about 40,000 inhabitants, and lies at the bottom of a small cove, in the gorges of an extensive pass which widens from this point as it advances into the interior. Its situation is picturesque, being surrounded by hills crowned with well-mounted fortifications, but its climate is sultry and unwholesome. It is next to Djidda the most important commercial town in Arabia, and its navigation extends over all the ports of Arabia, Persia, Africa, and India. The houses, except those near the beach, are but mean, the so-called palace of the imam not excepted. In its environs are the famous hot springs of Imam Ali. Contiguous to Mascat, lies Mattarah, or Mattrah, with 20,000 inhabitants, a seaport sharing in the commerce of the capital, with which it almost forms a twin town. The combined trade of these two ports is very important. Wellsted estimated the imports in 1836 at L.900,000, but they now are considerably above a million. They consist of manufactured goods from Great Britain and India; slaves, ivory, and other natural products from Africa; coffee from Yemen; salt, tobacco, and carpets from Persia, &c. The exports are fish, horses, grain, and other native products, and a large proportion of imported goods. Asses are exported to Persia and Mauritius. A new branch of export will open itself to Mascat, whenever it shall be thought fit to substitute the camel, as a hardy beast of burden, for the clumsy, easily-yielding draught-ox, in the colony at the Cape of Good Hope. Other towns are, along the coast, Sohar, with 9000 inhabitants, Sib, Burka, Khaburah, Shinas, Khadrawein, &c.; and in the interior, Rostak, a large town, Birket-el-Modj, the El Mal of Niebuhr, at the southern foot of Djebel Akhdar, said to be founded in the time of the great Nushirwan, king of Persia (A.D. 531–579), and remarkable for its lofty houses and two square watch-towers, 16 feet wide, and 170 feet high, the walls of which are only 2 feet thick at the base; Neswa, with a massive fortified tower, 140 feet high, surrounded by a like wall 40 feet high; Shirasi, in Djebel Akhbar, 5800 feet above the sea, in a lovely climate; Birema, in the north-west, 6000 inhabitants, with a like climate; and Obri, a large town quite in the west, and separated from Nedjed only by a narrow strip of desert. The northern peninsula has no places of note; but is remarkable for the narrow gloomy strait, leading through dark, perpendicular, and, in some places, overhanging rocks, from the Indian Sea to the Persian Gulf, between Ras-el-Djebel on the continent, and the island on which lies Ras Musendom, the north cape of Oman.

The imam of Mascat.

The most powerful prince in Oman is the imam of Mascat, Saiyid Said, who claims sovereignty over all Oman, but is only nominally obeyed by the settled population in the interior, and not at all by the Bedouins. In fact, the sheiks of Obri, Birema, and others, are quite independent. The title imam is only given to him by strangers and courtiers, since, of the two conditions necessary for obtaining that title, he has never fulfilled one, and has broken the other; that is, he has never preached a sermon before his assembled chiefs, and he has not only gone to sea, but is constantly sailing to and fro throughout his dominions. Although the latter condition has been dispensed with on previous occasions, the former is so imperative, that the natives withhold the title of imam from this powerful king, and only call him *saiyid*, or prince. Besides Oman, the imam possesses the islands of Kishm and others in the Persian Gulf; a large portion of the Persian coast which he farms from the shah of Persia, and where much bay salt is manufactured on his account; and the island and town of Zanzibar, on the East African coast, where he generally resides; as well as the town of Mombas and many others, with their respective territories, along the African coast. The imam, an ally of the British crown, is a sort of merchant prince, the principal part of the commerce and navigation of his scattered dominions being in his hands, and conducted on his account.

He is the mightiest potentate in those parts of the world. For the better keeping his scattered dominions together, he has a considerable number of men-of-war, of all sizes, which also serve as merchant-men for the conveyance of his own goods. In Wellsted's time, there were from 70 to 80 carrying from 4 to 74 guns, most of them small, but all built after European models, chiefly on the wharfs at Bombay. Besides these, there were from 60 to 80 armed bungalows, or one-masted Arabic vessels of from 200 to 300 tons, and balits, or smaller craft, of from 100 to 200 tons, which serve in the double capacity of convoy and transport vessels. To the late King William IV. the imam presented a fine 74-gun vessel, completely fitted out;

Arabia.

and the value of the presents he made to Her Majesty Queen Victoria, on her accession to the throne, was estimated at L.50,000, being all articles grown in his own dominions, or manufactured by his own subjects. In 1845, Prince Hilal, the son and heir of the imam, visited London, accompanied by two young Arabic chiefs, and made himself much beloved through the courteous simplicity of his manners, and the amiability of his disposition.

It is expected that the friendship between the British government and the imam will be a great support to travellers intending to explore Central Africa from the side of Zanzibar.

History.

Arabia has been peopled from the earliest times, but its ancient history seems to have been lost or corrupted in a long course of oral tradition. The narratives of the Arabian historians are absurd and fabulous, resting on no evidence; nor have later writers succeeded in withdrawing the veil of oblivion from the history of those early ages. The common notion among the Arabs is, that they are descended from Joktan the son of Eber, as well as from Ishmael the son of Abraham by Hagar; and the posterity of the former are denominated pure Arabs, while those of the latter are called *naturalized* or engrafted Arabs. Joktan had thirteen, or, according to the Arabian traditions, thirty-one sons, who, after the confusion of languages at Babel, are said to have settled in the south-eastern parts of Arabia, and to have gone afterwards to India, with the exception of two, namely, Yarhab and Jorham, the former of whom gave name to the country. Yarhab settled in Yemen, while Jorham founded the kingdom of the Hedjaz, where his posterity reigned. Ishmael being dismissed by Abraham, retired to the wilderness of Paran, where he married an Egyptian, by whom he had twelve children, who were the heads of as many potent tribes of the *Scenite* or wild Arabs. He afterwards, according to tradition, married the daughter of Modad, the king of the Hedjaz, lineally descended from Jorham; and is thus considered by the Arabians the father of the greater body of their nation.[1] By these tribes Arabia was ruled in ancient times, and a genealogical list is preserved of a long line of kings in Yemen and other provinces, of whom nothing further is known than the names. The ancient tribes who inhabited Arabia maintained flocks and herds. They were addicted to commerce and rapine, and frequently by their inroads molested the neighbouring states. They were invaded in their turn by the Assyrians, the Egyptians, the Medes, and the Persians; but whatever ancient historians may relate concerning the victories of Sesostris, it does not appear that either the Assyrians, the Egyptians, or the Persians, ever obtained any permanent footing in the country.

The Greek and Roman writers describe with accuracy the general features of Arabia, the scarcity of water in the desert, the deep wells known only to the inhabitants, and the pastoral and predatory habits of the people; and, in the fertile districts, the rich produce of corn, wine, oil, honey, frankincense, myrrh, and odoriferous gums; but this information is mixed with fabulous tales and absurd exaggerations. From the rare and precious produce with which Arabia abounds, the most fanciful ideas were formed of its vast wealth. It was said to possess abundant mines of precious stones, and gold, which was found in small pieces of the size of nuts, of the brightest colour and polish. (Diodorus Siculus, *Hist.* lib. ii. sect. 48.) This favoured land was besides supposed to be enriched by the peculiar nature of its commerce, its valued products being sold to other nations, while their produce was not required in return. The balance of trade was thus always in its favour; and, according to this hypothesis, a supply of gold and silver was perpetually flowing into it from all other countries.[2] Cassia and cinnamon are also erroneously mentioned as the products of Arabia, probably because they came directly to the Romans from that country, which has been in all ages the great depôt of Indian produce. The great lake, mentioned by the ancient writers, and said to contain bitumen, and to yield a large revenue, must be the Dead Sea, thus included by the ancients within the limits of Arabia; or the existence of this sea so near Arabia may have given rise to the report of another lake in the interior, which we know does not exist. Pliny says that the inhabitants shave their beards, with the exception of the upper lip—a custom which, if it ever existed, has not been transmitted to the modern Arabs, who hold the beard in peculiar honour; and the story of their promiscuous cohabitation, related by Strabo and Ptolemy, is entirely contradicted by all the latest and most authentic accounts of Arabian manners.

In describing the zoology of Arabia, the ancient writers give an accurate account of the camel and the dromedary; but some of them assert that the country contains no horses, for which in modern times it has been so famed; and their description of the ostrich is altogether fabulous and absurd. Pliny asserts that it exceeds the height of a man on horseback; Diodorus, that it is of the size of a new-born camel, that it throws stones with its feet at its pursuers, and adds various extravagant and unfounded details of its habits and the manner of its death. Ptolemy was the first writer who divided Arabia into three parts; namely, Arabia Petræa, Arabia Deserta, and Arabia Felix; which division, agreeing with the natural features of the country, is still recognised. Ptolemy and also Pliny give a long list of towns, and of the various tribes which ranged over the country. The site of Petra, that splendid capital of Arabia Petræa, was rediscovered by Burckhardt, a silent necropolis in a deep, inaccessible wadi. The nations who inhabited this tract were the Ishmaelites, the Nabatheans, the Cedrei or Kedareni, and the Hagareni, all which appellations have in later times been lost in that of the Saracens, so celebrated for several centuries all over the East. Numerous towns are mentioned in Arabia Deserta, of which, being originally of little note, all knowledge is now lost; and of the tribes of the Æsitæ and the Agræi we know nothing but the names. Arabia Felix was the chief seat of population and of wealth. It included the fine provinces of Yemen, Hedjaz, Tehama, Nedjed, and Yumama. It was inhabited by many different tribes, such as the Sabæi, who from the account of Pliny were a powerful tribe, trading in frankincense, and extending from sea to sea, either from the Red Sea to the Indian Ocean, or to the Persian Gulf;[3] by the Minæi, Atramitæ, Marinatæ, Catabani, Ascitæ, Homeritæ, Sapphoritæ, Omani, Saraceni, &c., of whose history nothing is now known. The towns of Yaman or Yemen were, Aden, the *emporium Arabiæ* of Ptolemy, on the Indian Ocean; and Musa, the modern Mocha; both noted marts of trade, at which were exchanged the precious produce of the country (consisting of myrrh, frankincense, perfumes, and pearls, of which there was a noted fishery near some islands in the Red Sea), for goods brought by the annual fleets from India. Those goods appear to have been landed at Aden or Musa; to have been carried northward in caravans to Leucocome, or Portus Albus, in latitude 25° N.; then, according to Strabo,

[1] *Universal History*, vol. viii. chap. ix.

[2] Plin. *Historia Naturalis*, lib. vi. cap. 32. "In universum gentes ditissimæ, ut apud quas maximæ opes Romanorum Parthorumque subsistant, vendentibus quæ e mari aut silvis capiant, nihil invicem redimentibus." Strabo (lib. xvi.) mentions that they sold their gums for precious stones and for gold; and that the invasion of Arabia under Augustus, by Ælius Gallus, was prompted by the desire of attaining the alliance of rich friends, or the conquest of rich enemies. If these ancient writers had been versed in the modern doctrines of political economy, they would have known that the balance of trade could not have been permanently in favour of a country which abounds in gold.

Arabia.

to have been transported across the Red Sea to Myos Hormos, near the modern Cosseir; and being carried on camels to Coptos, in the Thebaid, a port on the Nile, to have been thence floated down in boats to Alexandria. Sanaa, the capital of Yemen, of great antiquity, is supposed to be the Saphor of Ptolemy; and Mareb, the modern Saba, which was a large, opulent, and strong city, is now an inconsiderable village. On the Persian Gulf was situated the port of Moscha, now the city of Mascat; and Gerra or Khatif, which, Pliny and Strabo mention, had turrets and houses formed of square masses of salt, some of which are still to be seen in the country. In the Hedjaz was Macoraba or Mecca, the seat of a very ancient temple; and Yathrib or Lathrippa, the modern Medina. Djidda, the port of Mecca, is seldom noticed by the ancients; and Yembo, the port of Medina, is the Jambia of Ptolemy. The frequent incursions of the Arabs into the neighbouring regions exposed them to retaliation from hostile armies; but the aridity of the country was ever found to be its true defence. It was in vain that the invader vanquished the Arabs in the field; they fled from his pursuit on their horses and camels, and quickly disappeared in the burning desert, whither no army ever dared to follow them. The northern provinces bordering on Syria were invaded by Antigonus, and afterwards by Pompey, though they never succeeded in acquiring possession of Petra, the great stronghold of the country. But the most important expedition of the Romans was that of Ælius Gallus, in the reign of Augustus, who, with a force of 10,000 troops, of whom 500 were Jews, and 1000 Nabatheans, natives of the country, landed at Leucocome, in latitude 25° N., about 70 miles north-west from Medina, and in the following spring, his troops having been till that time disabled by disease, he advanced southward, crossed a desert of 30 days' journey, and in 50 days more arrived in a pleasant and fruitful region, where he took by assault a city called Najran. He continued his march southward for other 60 days; and being finally compelled to retreat by fatigue and disease, he crossed the Red Sea, and, landing his troops at Myos Hormos, on the Egyptian shore, brought back the poor remains of his army to Alexandria, after an absence of two years.[1] The situation of the towns in his route being entirely unknown, we cannot trace his course, though it must have been in the direction of Medina and Mecca. The great historian of the Decline and Fall of Rome places the march of Ælius Gallus between Mareb or Mecca and the sea.[2] But this is a desert tract, in no respect resembling the character given of the country into which he penetrated, which may therefore probably be the elevated tract on the Hedjaz ridge of mountains, extending north and south parallel with the Red Sea. Northern Arabia was also invaded by the Emperors Trajan and Severus, but they effected no settlement in the country; and though the cities of Bosra and Petra were at one time reduced by a lieutenant of Trajan, yet the Romans never seem to have extended their power over Arabia Petræa. On the decline of the empire Syria was invaded by the Arabian freebooters, who sometimes drew on themselves severe retaliation. The doubtful frontier of the respective territories was thus a constant scene of hostility, until the Arab tribes, inspired by the genius of Mahomet, advanced to permanent conquests.

Jews were numerous in the Arabian seaports ever since the remote period when they monopolized the trade with Ophir and the spice countries on the Red Sea. After the destruction of Jerusalem, whole tribes of Israelites found an asylum in Arabia, where they became so powerful that Dunaan, a Jewish chief, succeeded in defeating and killing Er Riad, commonly called Aretha, the Christian (Arian) king of Himyar, in which country he assumed the royal power. But this Jewish kingdom did not continue many years, as it was conquered by Eleesbam, the Christian king of Abyssinia, who killed Dunaan. In the age of Mahomet, the Jews were very numerous and powerful in Arabia, and in spite of the persecutions which they had to suffer from him and his successors, there are even in our days great numbers of settled Israelites natives of Arabia, to be found in the seaports and wherever the fanaticism of the Arabs suffers them to dwell. In the interior Jewish tribes are met with leading a wandering life like Bedouins.

Mahomet.

Such are some of the early traditions and imperfect sketches of Arabian history. We now approach a new era, not only of greater certainty, but containing events of far deeper interest, and of lasting importance. The rise and progress of Mahomet, the prophet of the East, and the rapid propagation of his faith, which has changed the moral and political aspect of the eastern world, forms a most singular chapter in the history of human affairs, an account of which will be found under MAHOMET.

His death exposed the new state to the dangers of a disputed succession. The right to the throne, on which subject Mahomet was silent when he died, was respectively claimed by two powerful tribes, namely, those who fled to Medina with the prophet, or the *fugitives*, and those who aided him on his arrival, or the *auxiliaries*. To terminate this dangerous dispute, Omar, renouncing his own pretensions, held out his hand to Abubekr as his future sovereign; and his authority was recognised in all the provinces. The Hashemites, under Ali their chief, though averse to the new monarch, acknowledged him after some time as commander of the faithful. After a reign of two years he was succeeded by Omar, who was assassinated in the twelfth year of his reign, and was succeeded by Othman; and it was not till his A. D. 634. death that Ali ascended the throne. This contest for the dignity of caliph has ever since divided the Mahometans into the two hostile parties of the Shiites or sectaries, who reprobate as usurpers Abubekr, Omar, and Othman; and the Sonnites, who revere them along with Ali as the legitimate successors of the prophet. This schism is the source of the hatred which still exists between the Persians and Turks.

Arabia, during the reign of these several princes, was filled with distraction at home, while the most splendid conquests were achieved abroad. To give a detail of these events, which relate besides to other countries as much as to Arabia, would exceed our limits. We may therefore briefly observe, that during the short reign of Abubekr, the Syrian territories of the Greek emperor were overrun by the victorious Moslems under Abu Obeidah, and afterwards under Khaled, surnamed from his valour and fanaticism the sword of God; that the Greek armies were overthrown in several decisive battles; and that the rich and populous cities of the country, including Bosra and Damascus, were stormed by the barbarian invaders. A new army, raised by the Greek emperor, the last hope of the falling empire, was scattered before the barbarian host in the decisive battle of Yarmuk. Palestine was now subdued, and Jerusalem, which was reputed a holy city by its ferocious conquerors, and was visited by the Caliph Omar. Here he directed Amrou to invade Egypt, which was rapidly overrun; and his other lieutenants to complete the conquest of Syria. His orders were punctually obeyed, and Aleppo, Antioch, Tyre, Cæsarea, and all the other cities and fortresses in the province, A. D. 640. were successively taken.

On the east the empire of the Arabs was rapidly extended. "They advanced," says the eloquent historian of the Decline and Fall of Rome, "to the banks and sources of the Euphrates and Tigris; the long-disputed

[1] Dion Cassius *Hist. Rom.* lib. liii. sect 29.

Arabia. barrier of Rome and Persia was for ever confounded; the walls of Edessa and Amida, of Dara and Nisibis, which had resisted the arms and engines of Sapor or Nashir-
A.D 637. van, were levelled in the dust." The fate of Persia was decided in the great battle of Cadesia. The victorious Arabs poured like a flood over the country, and acquired prodigious spoil; nor did they halt in their victorious career till they had reached the banks of the Oxus, and had added to their empire Herat, Merou, Balk, Samarcand, and other rich and trading cities in the East.

The short reign of Ali, from the year 655 to 661, was disturbed by domestic dissension and the rival claims of Moawiyah, the son of Abu Sophian, well known for his tardy and reluctant obedience to the sword, as was alleged, rather than to the doctrines of the prophet. The death of Ali by an assassin was the signal for new contests. Moawiyah reigned at Damascus, which was the new capital of the caliphs of the house of Ommiyah, and was succeeded by his son Yezid A. D. 680, whose title was disputed by the surviving family of Ali, Hozein and Abdallah Ebn Zobeir, his two sons. They fled from Medina to Mecca; and Hozein was proceeding to Cufa on assurances of aid from the inhabitants, when he was surrounded and barbarously murdered, with all his followers, by Obeidallah the governor. Abdallah, the sole representative of the house of Hashem, was now proclaimed caliph at Medina, from which city he expelled all the adherents and dependents of the house of Ommiyah, to the number of 8000. Yezid dispatched a large force to their aid, by which Medina was taken, after a vigorous defence, and abandoned to pillage. Mecca, besieged by the army of Yezid, was on the point of sharing the same fate, when intelligence was received of Yezid's death. His son,
A. D. 684. Moawiyah II., succeeded him, and, after a reign of six weeks, died without naming a successor. Serious commotions now ensued. Merwan, of the house of Ommiyah, was proclaimed caliph at Damascus, while Abdallah reigned at Mecca. The former was succeeded by his son Abdalmalac, during whose reign the contest for the throne was terminated by the death of Abdallah, who, in a desperate sally from Mecca, where he was besieged by the troops of the rival caliph, was overpowered and slain. By his death the sovereignty was firmly established in the line of the Ommiades, who reigned in Damascus above 70 years.

But the title of this dynasty not being founded on any clear principle of religion or of law, was never recognised by the great body of the Moslems. They regarded with veneration the lineal descendants of the prophet, who on their part still cherished the hope of reigning over the Moslem empire. Numerous partisans of the line of Abbas were dispersed throughout the provinces, and secret plots for their restoration were gradually matured into rebellion. The last caliph of the line of the Ommiades was met on the field by a powerful army commanded by Abdallah, the uncle of his rival; and after an irretrievable defeat he escaped to Mosul, and finally to Egypt, where he was defeated and slain, and the last remains of his party extinguished. Amid the ruin and massacre of his family by the conqueror, a royal youth, Abdalrahman, alone escaped, and making his way into Spain, laid the foundation of a new dynasty of the Ommiades, who reigned in Cordova with great splendour for 250 years, from the Atlantic to the Pyrenees. In Egypt and Africa the Fatimite caliphs, the progeny of Ali, were invested with royal authority; and the new line of the Abassides transferring the seat of government from Damascus to the banks of the Euphrates, laid the foundation of Bagdad, the seat of their empire, and of wealth, literature, and science, for 500 years. Arabia.

In the course of these various revolutions and splendid conquests, Arabia, the original seat of the Mahometans, had dwindled into an inconsiderable province of their vast empire, and the rude inhabitant of the desert retained his solitary independence, heedless alike of distant victories as of domestic changes. The Hedjaz, the mountainous district of Arabia, and the chief seat of its commerce and its towns, was governed by the lieutenants of the caliphs,[1] or sherifs as they are called, who are chosen from the tribe of the Koreish, and who have always acted as the resident sovereigns of the country. But their power was unknown in the desert, where the scheiks still continued to rule. In the disorders attending the decay of the Mahometan power, Arabia was occasionally invaded by hostile tribes; but it was chiefly the outskirts of the country that were scathed by the flame of war, which never penetrated to the interior. It appears from the incidental and scattered notices which we possess, that about the year 1173 Sultan Saladin subdued a king who reigned in Yemen, and who had revolted against the authority of the caliphs of the line of Abassides. Having reduced the country, he committed the government to two deputies, who afterwards claiming independent power, were in their turn reduced by the troops of Saladin. In 1517, when Selim I. conquered Egypt, and extinguished the last surviving representative of the second dynasty of the Abassides, the sherif of Mecca brought to him the keys of the city; and the Arabian tribes professed their allegiance, and gave hostages as a pledge of their fidelity. The country continued under subjection for 50 years, when Muttahir, sherif of the kingdom, impatient of the Turkish yoke, attacked and routed the army of Murad Pacha, and freed the country for a time from its oppressors. A powerful army, commanded by the governor of Egypt, was dispatched by Selim II. to Yemen; the Arabian force was defeated and dispersed, and the authority of the sultan was re-established in Yemen, and extended backwards to the highlands. The country, thus reduced, was governed as a Turkish province by pachas sent from Constantinople. But in the interior the independent princes and scheiks still retained their authority, and continued to harass the Turks, and to drive them back to the coasts. They were expelled from the province of Yemen about the middle of the 17th century; and since this period until the invasion of the country by Mohammed Ali they have only possessed a precarious and nominal authority in the towns of Djidda and Mecca.[2]

The rise of the sect of the Wahabys, and the rapid Wahabys extension of their dominion and doctrines, forms a most important epoch in the more recent history of Arabia. These sectaries were the reformers of religion in the East. They were zealous followers of Mahomet, who were scandalized by the departure of modern believers from the simplicity of the faith; by their worship at the tombs of saints; by the luxurious ostentation of their dress; their remiss attendance at public prayers; the immorality of their lives; the scandalous indecencies which they practised in the holy temple of Mecca; and

[1] "Depuis ce tems-là (de Mahomet) les Arabes de l'Iemen (Yemen), et de toutes autres provinces de l'Arabie, sont toujours demeurés sous l'obéissance des Khalifs, ou de Bagdet ou Egypte, tant que le Khalifat a durée." (Herbelot, *Bibliothèque Orientale*, Iaman.)

Arabia. finally, in opposition to the strict prohibitions of the Koran, by their free use of tobacco and other intoxicating drugs.[1] Such were the chief articles of the new creed, which, in the same manner as the faith itself, was propagated by fire and sword. Its founder was Mohammed-Ebn-Abd-el Wahab, the son of a scheik in an obscure village, born in the year 1691, whose history and success for nearly a century seemed to presage the final triumph of his doctrines and his arms. It is remarkable that the only two great revolutions which have ever taken place in Arabia have had their origin in religion. It was in both cases for religion that the sword was ostensibly drawn. The subjection or extinction of infidel tribes was a step in the progress of the pious work; and these objects being accomplished, the original design, however spiritual in its nature, necessarily terminated in conquest and political dominion. The young apostle of the new faith was trained in the strict principles of Mahometanism. He was sent to finish his studies in the university of Bassora; and on his return to his native village, commencing reformer of religion and of manners, he was banished by the governor. He took refuge in Derayeh, the capital of Nedjed, where he was protected by the scheik Mohammed-Ebn-Saouhoud, a zealous disciple, from political views, as was insinuated, of the reformed faith. Here the new tenets were embraced by crowds of proselytes, eager to draw their swords in the cause of truth; and so well did the Wahaby chief Saoud profit by their new-born zeal, that before his death in 1765 he had extended his faith and his dominion over the whole province of Nedjed. His son Abd-el-Azyz enlarged by new conquests the power of the Wahabys. He subdued and rendered tributary the surrounding tribes, threatened the holy cities, and finally spread the terror of his arms over all the northern parts of Arabia, from Mecca and Medina to Damascus, Bagdad, and Bassora. Mohammed-Ebn-Abd-el Wahab, the founder of the Wahaby sect, died in 1787, at the advanced age of 95. But this event noway damped the zeal of his followers. Their expeditions were dreaded all along the banks of the Euphrates, and in the neighbourhood of Bassora, which they invaded every year, committing great excesses, and massacring the Arab settlers who were the subjects of the Bagdad government. In 1797 the pacha of Bagdad undertook an expedition against Derayeh, the capital of the Wahabys. He was repulsed by Saoud, the son of the reigning chief, who continued his inroads into the Turkish territories on the Euphrates. In 1801 he stormed the town of Imam Hosseyn, where, according to the intolerant maxims of the new sect, 5000 persons were massacred.

Ghaleb, the sherif of Mecca, was alarmed by the conquests of the Wahabys, and since the year 1792 had been vainly contending against their rising power. In 1801 the sectaries invaded his dominions in great force. In 1802 they stormed the town of Tayf, which they gave up to a general massacre, in which neither men, women, nor children were spared. In 1803 the holy city, notwithstanding the brave resistance of Sherif Ghaleb, surrendered at discretion to the victorious Wahabys. On entering it, the strictest discipline was preserved by Saoud the chief, and not the slightest excess was committed. The inhabitants were, however, compelled to a more punctual attendance at prayers; to conceal their silk dresses; all their finely ornamented Persian pipes were collected before Saoud's house, and there committed to the flames; and the sale of tobacco was forbidden. Mecca was afterwards given up to the government of Sherif Ghaleb, on the usual condition of his conversion to the Wahaby faith. This conquest was followed by the reduction of the neighbouring tribes, and in 1804 Medina surrendered to the Wahaby arms. Here they rigorously enforced the duty of public worship; the absent were punished; and a respectable woman, accused of smoking the Persian pipe, was placed upon a jack-ass, and paraded through the town with the pipe suspended round her neck. Saoud soon after visited Medina, and carried away from the tomb of Mahomet all the valuable articles, namely, jewels and pearls, and Cufic manuscripts of the Koran, which it contained; and ordered his troops, according to the approved maxims of his sect, who reprobate the worship of saints, to destroy the cupola over the tomb; but it was so strong that with all their efforts they could not deface this curious relic of antiquity.

The Hedjaz continued to enjoy tranquillity during the years 1806, 1807, and 1808, under the divided rule of the sherif of Mecca and of the Wahabys, the power of the former gradually declining, while Saoud was acknowledged as pontiff and king over the greater part of Arabia. The Wahaby hordes extended their inroads southward into the mountains of Yemen, whence they descended to the coasts and plundered the towns of Loheia and Hodeida. On the north they advanced into the Syrian desert, and alarmed the Bedouins in the vicinity of Aleppo, as well as the inhabitants of Damascus, who had begun to send away their valuable property to the mountains of Libanus. The Mesopotamian tribes near Bagdad were attacked and pillaged; and in 1810 Saoud, at the head of 20,000 troops, stormed the Persian town of Kerbeleh, putting all the male inhabitants to the sword.[2] The regular intercourse of the great pilgrim caravans from Syria, Egypt, Persia, and Yemen, had been interrupted since the year 1803, and the few scattered pilgrims that reached the holy cities from the north and west generally came across the Red Sea from Cosseir to Djidda.

The surrender of Mecca and Medina to the sectaries, and the interruption of the pilgrimages, excited the shame and indignation of all pious Mahometans. Mohammed Ali, who in 1804 was appointed pacha of Egypt, received instructions from the Porte to undertake the reconquest of the Holy Land. He accordingly determined on the invasion of Arabia, and prepared an expedition which he committed to his son Tousoun Bey, and Ahmed Aga his treasurer. The infantry, amounting to 2000 troops, landed at Yembo from Suez in October 1811, and took the town after a slight resistance. In January 1812 Tousoun advanced against Medina; but he was assailed in the mountain passes, through which his route lay, by a powerful army of Wahabys, and utterly routed, with the loss of all his baggage and artillery. Being in the course of the summer largely reinforced from Egypt, he again advanced to Medina in November; and having sprung a mine and overthrown part of the wall, he carried the town by assault, massacring about 1000 of the garrison in the streets. The remainder, to the number of 1500, retired to the castle, which they afterwards surrendered on condition of receiving a safe conduct for themselves and baggage; in defiance of which they were, on quitting the town, treacherously massacred by the Turkish troops. Sherif Ghaleb, intimidated by the capture of Medina, now intimated his desire of surrendering the holy city to the Turkish commander. Mecca, with Djidda, its port, was accordingly taken possession of in January 1813 without any opposition; and in a fortnight the town of Tayf, which had been held by the Wahabys for sixteen years,

[1] Felix Mengin, *Histoire de l'Egypte sous le Gouvernement de Mohammed Ali*, tome I. p. 379.

[2] *Ibid.* tome I. p. 380.

surrendered after a feeble resistance.[1] In 1813 Mohammed Ali landed at Djidda; and on his arrival at Mecca, suspecting the hostile intrigues of Sherif Ghaleb with the Arab tribes, he caused him to be arrested and sent under a guard to Egypt. He was succeeded in the government of Mecca by Yahya, also of the sherif family, the humble tool of Mohammed Ali. In the mean time the Turkish army, weakened by its losses, remained at Mecca and Tayf; and, with the exception of an unsuccessful expedition against Toraba, the chief town of the southern Wahabys, and the capture of Gonfode, a port seven days' journey south of Djidda, which was soon after recaptured, no enterprise of any importance had been undertaken since the surrender of Mecca and Tayf. But Mohammed Ali was not idle. He employed the time in reinforcing his wasted army, in collecting magazines and stores, in purchasing camels, and in strengthening his influence among the Arab chiefs, many of whom he succeeded in detaching from the Wahabys by the influence of presents and money.

Saoud, the successful chief of the Wahabys, died at Nedjed in 1814, and his son Abdallah, who succeeded him, though he was brave, was inferior to his father in all the qualities of a political chief. The pacha having completed his preparations, now resolved to strike a decisive blow. In January 1815 he began his march southward in the direction of Toraba. The Wahabys, to the number of 25,000, occupied a strong position on the mountains near Byssel, from which, after some unsuccessful attempts to dislodge them, he contrived, by a feigned retreat, to draw them into the plain. Here their disorderly host was borne down by the steady attack of the pacha's disciplined force, and flying in confusion, they were cut down without mercy by the Turkish cavalry. A reward of six dollars being offered for the head of every Wahaby, 5000 of these bloody trophies were in a few hours piled up before the pacha's tent. Of 300 prisoners who were taken, 50 were, according to the cruel maxims of the East, impaled alive before the gates of Mecca, and the rest at other parts. Mohammed Ali hastened to profit by his victory. He arrived in four days before Toraba, which capitulated; and advancing southward, he encountered the wreck of the Wahaby army in the mountains near the town of Beishe. Here, after a brave resistance under Tamy, their chief, who was seen riding in front, animating the troops by his war songs, they gave way before the Turkish artillery. Tamy, who was betrayed into the hands of his enemies by an Arab chief, and by his gallant bearing gained the esteem of the whole army, was sent to Constantinople, where he was instantly beheaded. Another chief, Bakhroudj, was tortured to death in presence of the pacha. The Turkish army continued the pursuit of the Wahabys, and subdued most of the southern tribes. Mohammed Ali was intent on carrying the war into Yemen, whose rich cities he hoped to plunder; but the wasted state of the army forced him to an immediate retreat. He himself accordingly proceeded to Gonfode on the sea-shore, and arrived at Mecca on the 21st of March, after an absence of 15 days. Of his army, consisting of 4000 Turks, he brought back only 1500; and of 10,000 camels, only 300 survived the fatigues of the campaign.

The war against the northern Wahabys was prosecuted with vigour by Tousoun Pacha, who had advanced eastward from Medina to Khabara, about 300 miles into the interior of the country. Abdallah had fixed his head quarters at Shenana, only five hours' march from the Turkish army. Tousoun was here seriously embarrassed by the want of supplies. His treasurer Ibrahim Aga,[2] with a detachment, had been some time before surrounded on the road and cut to pieces, after a gallant resistance, and his remaining troops were averse to a battle. From these difficulties he was extricated by a peace, which Abdallah weakly concluded with him, and by which he agreed to renounce the possession of the holy cities, to be ranked among the faithful subjects of the sultan, to pray for him in the mosques, and to submit to his authority as his sovereign. But this treaty, however disgraceful to the Wahabys, was far from satisfying the views of Mohammed Ali, who, with his usual contempt of all engagements, refused to ratify it; and conscious of his strength, would enter into no overtures from Abdallah, however humble, having determined either to reduce or to exterminate the rebellious sectaries of Arabia of which he was the head. Both parties accordingly prepared for war. In September 1815 Ibrahim Pacha, son of Mohammed Ali, landed at Yembo with 2000 Turkish troops, besides 2000 peasants pressed into his service at Siout on the Nile, amid the outcries of their wives and children. He had also a corps of 500 Moggrebins from Barbary. Having spent some time at Medina in reducing the surrounding tribes, and visiting the holy sepulchre, he directed all the troops which could be spared from the different garrisons to march on Hanakye or Henakyeh, about 100 miles eastward of Medina, where, early in December, his whole force was concentrated. Here he remained till the end of April 1817; and though his troops suffered severely under fever and dysentery, the diseases of the climate, he succeeded, by several bold and well-concerted expeditions, in impressing on the Arab tribes the terror of his arms. He extended his alliances among them, and by his policy as well as by his arms he silently prepared the ruin of the Wahaby state. In the conduct of the war Ibrahim combined, with the cruelty of a Turkish conqueror, undaunted courage and skill, a rare perseverance under difficulties, and a fertility of resource which seldom failed him. The discipline of his troops secured his superiority in the field; and the Wahaby host, avoiding the risk of a battle, relied on their fortresses, the nakedness of the land, and the noxious climate. The issue of the war was thus reduced to a mere arithmetical question of the number of men that would be required to carry it on. These being provided, the conquest of the country was certain, and Mohammed Ali was too well versed in war not to see the advantages which he possessed, and too deeply interested to grudge the necessary supplies. He was willing to pay the fair price of his success. The army of Ibrahim, notwithstanding its losses, was accordingly maintained at its full complement by recruits from Egypt; and he now hastened to complete the conquest of the country by reducing its strongholds, and especially Derayeh, its capital. He had gone to the village of Maouyeh, where he was joined by a powerful chief; and having assembled all his forces, consisting of 4000 infantry and 1200 horse, besides his Arab auxiliaries, he advanced in July to the fortress of Rass. In three several assaults, conducted with desperate valour, but without skill, the assailants were overwhelmed, and finally repulsed with severe loss, by the well-directed fire of the

[2] Ibrahim Aga was a native of Edinburgh, named Thomas Keith, a private in the 72d regiment of highlanders, and taken prisoner in the last expedition of the English to Egypt. He became a mussulman, and on account of his valour was promoted to the high office of treasurer by Tousoun Pacha.

garrison; and Ibrahim, after vainly contending for three months and 17 days against the obstinate valour of the inhabitants, and incurring a loss of 3400 men, was forced to raise the siege of an ill-fortified place, which, with the aid of engineers, he might have reduced in two days. But this was the only disaster which befell the Turkish arms. The sequel of the campaign was one continued course of conquest. Khabra, Aneyzey and its castle, and Banneydeh, successively fell after a slight resistance. At the latter place the Turkish army remained for two months. Having received large reinforcements, it commenced its march, accompanied by a train of 10,000 camels and other beasts of burden, across frightful deserts of sands, and in January 1818 encamped at Chakra, which was taken after a siege of seven days. The town of Dorama was stormed after a brave resistance, and abandoned to pillage and the sword; and on the 22d of March, Ibrahim directed his victorious march to Derayeh, the capital, and last stronghold of the Wahaby state. This place, which consists of five small towns, each surrounded with a wall protected by bastions at small distances, was now closely besieged by the Turkish army, which, including infantry and cavalry, amounted to 5500 troops. The siege was long and obstinate, but the Turkish troops still maintained their superiority. The different divisions of the town were successively stormed; and the unfortunate Abdallah, thus driven to his last retreat, was reduced to ask a suspension of arms and a conference. His interview with Ibrahim presented a touching spectacle of fallen dignity. He demanded peace: the conqueror granted his request, but added that he was not authorized to leave him at Derayeh,—the positive order of his father was that he should repair to Egypt. Abdallah, after 24 hours of deliberation, intimated his assent to the proposed terms, and only conditioned for his life. Ibrahim would not answer for the decision either of his father or the sultan, farther than that he thought them both too generous to take his life. Abdallah, having bidden a last adieu to his afflicted family, repaired to the tent of Ibrahim, from which he set out on his journey across the desert, and arrived at Cairo. He was sent to Constantinople, where, notwithstanding the intercession of Mohammed Ali, he was beheaded, along with his companions in misfortune, in the square of St Sophia, after being exhibited in every part of the city for three days. With the death of Abdallah terminated the dominion of the Wahabys, which, under a succession of vigorous and politic princes, had in the course of a century been extended over the whole peninsula of Arabia. But their empire, loosely held together by the tenure of recent conquest, was overthrown by the first attack to which it was exposed. The chiefs who yielded to the terror of the Wahaby arms, deserted on the first appearance of a hostile army; others were seduced by the influence of gold, which was liberally distributed; and domestic dissension coming in aid of foreign war, dissolved the union of the tribes, and completed the ruin of the country. According to M. Mengin, whose information is undoubted,[1] Arabia had ample means of defence, in the difficulties of the country, and in the numbers, intrepidity, and discipline of its troops; and, with an able leader, he expresses his strong and apparently just conviction, that the Turkish army, in place of conquering the country, would have perished in its burning deserts.

The ruin of the Wahabys is deeply to be regretted, as it may throw back for several centuries the civilization of Arabia. The Wahaby princes reformed the morals as well as the religion of their country. Under the reign of Saoud the administration of justice was rigid and impartial. The crimes of rapine, thieving, and murder, so common among the Arab tribes, were severely punished; an exact police was established throughout the country; and caravans and travellers were seen journeying on all the roads in perfect security. The Turkish conquests will restore the primitive barbarity of the Arabian manners, and anarchy and crime will resume their wonted sway. But Arabia contains within itself the seeds of independence. The distance of Nedjed from Cairo, and the expense and difficulty of sending supplies through the interior deserts, will render it extremely difficult to maintain a Turkish force in the heart of the country; while the religious principles of the tribes, their warlike character and love of freedom, animating them to new efforts, may yet enable them to triumph over the foreign tyranny which oppresses them, and to re-establish their freedom on a new and a more secure basis.

The expeditions of Mohammed Ali against the Wahabys of Assyr, between 1824 and 1827, and again in 1833 and 1834, led to no lasting advantage for the Egyptian power. Since then, there have been frequent gatherings of the Wahabys in various parts of the peninsula; and there can be no doubt, that, should the decline of the Turkish empire continue, those intrepid and persevering reformers of a decrepit religion will ere long recover their former power. Only a few years ago, in 1850, they made a successful attempt upon Mecca and Medina, conquered both cities, and occupied them for a considerable time.

(D. B—N.) (W. P—E.)

ARABICI, a sect which sprung up in Arabia about the year 207, whose distinguishing tenet was, that the soul died with the body, and also arose again with it. Eusebius (lib. vi. c. 38) relates that a council was called to stop the progress of this rising sect; and that Origen assisted at it, and convinced them so thoroughly of their error that they abjured it.

ARABISM, ARABISMUS, an idiom or manner of speaking peculiar to the Arabs or the Arabic language.

ARABIST, a person curious and skilled in the learning and language of the Arabians: such were Erpenius and Golius. The surgeons of the thirteenth century are called *Arabists* by Severinus.

ARACAN. See ARRACAN.

ARACHIS, a genus of plants of the natural order Leguminosæ. The only known species is *A. hypogæa*, much cultivated in warm countries, and known by the inappropriate name of *Earth-nut*. It grows in sandy soils in southern Europe, in Africa, and Asia. The seeds contain a bland oil, and taste like sweet almonds.

ARACHNE, in *Fabulous History*, a Lydian maiden who is said to have been the inventress of spinning. She is fabled to have been so proud of her skill in this art as to challenge Minerva to compete with her. The goddess, inflamed with jealousy, struck Arachne and tore her work, upon which she hanged herself in despair. Minerva, from compassion, brought her to life, and transformed her into a spider, which still employs itself in spinning.—Ovid, *Met.*, vi. 1–145.

[1] M. Felix Mengin landed in Egypt with the French expedition under Buonaparte. He remained in Cairo for 20 years after the country was evacuated by his countrymen, where he collected much valuable information respecting the internal administration of Egypt and the Wahabys. His account of this Mahometan sect is derived from the grandson of Ebn-Abdul-Wahab, its founder.

ARACHNIDES,

FROM ἀράχνη, a *spider*, and εἶδος, *resemblance*, a class of invertebrated animals, formerly regarded as true insects, and as such classed by Linnæus in his order Aptera, under the generic names of *Phalangium*, *Aranea*, *Acarus*, and *Scorpio*. The Arachnides were first formed into a distinct class by M. Lamarck, whose arrangement of the Linnæan Aptera is admitted by Latreille to approach the most nearly to the natural order.

The third primary division in the system of Cuvier, that of the articulated animals (*animalia articulata*), contains four great classes, viz. ANNELIDES, CRUSTACEA, ARACHNIDES, and INSECTA. We have already stated our intention (see ANIMAL KINGDOM) to treat of the first of these classes under the title of Helminthology, of the last under Entomology, and of the two intermediate classes in the order of their alphabetical occurrence. We shall therefore now proceed with the history and classification of Arachnides.

The naturalists who preceded Lamarck appear to have confounded this class either with the true Insecta, or with the crustaceous tribes, such as crabs and lobsters. It was in the course of his public lectures (in 1800) that the last-named observer instituted for their reception a separate class, under the title which they now bear.

Cuvier, in one of his earliest works (*Tableau Elémentaire de l'Hist. Nat. des Animaux*, 1798), continued, with his contemporaries, to class the Arachnides with insects, of which he regarded them as forming the third principal division, preceded only by the Crustacea and Myriapoda; thus far departing from and improving the old Linnæan system, by assigning them a higher place in his general arrangement, but not yet admitting them to the honour of a separate class.

Lamarck published the first edition of his *Système des Animaux sans Vertèbres* in the year 1801, and he there explains the reasons which induced him to form the separation previously advocated in his lectures.

M. Latreille did not admit the *classic* separation of the Arachnides, either in his *Histoire Naturelle de Crustacés et des Insectes* (1802–5), or in his later work, the *Genera Crustaceorum et Insectorum* (1806–7), but merely placed them at the head of the class of insects. In a subsequent volume, however (*Considérations Générales sur l'Ordre Naturel des Crustacés*, &c. 1810), he practically admits the propriety of M. Lamarck's views; and in it we find the Arachnides forming a separate class, and constituted of the same materials as those used by his predecessor. In that portion of Baron Cuvier's *Règne Animal* (vol. iii. 1817) of which M. Latreille is the author, we find the same arrangement followed, with this exception, that in the last-named work the Myriapoda and Chelopoda are removed from the Arachnides and placed at the head of the class Insecta—a modification likewise adhered to both in the *Familles Naturelles du Règne Animal* (1825), and in the recent edition of the *Règne Animal* itself (1829), which contains the latest view of M. Latreille. By these, in as far as concerns our general principles of arrangement, we shall be chiefly guided in the course of this article; but we conceive it due to M. Lamarck to present our readers, in the first place, with a short statement of his opinions.[1]

He defines the Arachnides as follows: Oviparous animals, at all times provided with articulated legs,—not subject to metamorphoses, nor ever acquiring new kinds of organs. Respiration tracheal or branchial: stigmatiform openings for the entrance of the air. A rudimentary heart and circulation in the greater proportion of species. Copulationes plures per vitam in plurimis.[2]

It is known that no vertebrated animal provided with feet has ever more than four; and that among such as are invertebrated, those which in a state of complete development are provided with feet, have never less than six. Amongst invertebrated animals, insects have essentially the smallest number of feet; for the various orders and families of that class, when arrived at their final development, have never more than six. They are hence called *hexapods* by some modern writers. It is otherwise, however, with the Crustacea and Arachnides, the greater proportion of which have more than six feet. Certain species, in their earliest state, have no more than that number; but their other feet appear as they advance in age. A few are hexapod, or six-footed, during the entire term of their existence; but in addition to those characters which determine the class to which they belong, various other relations connect them with their congeners, and show that they are not genuine insects.

Among those articulated animals which possess no system of circulation, insects alone undergo genuine metamorphoses; and none of the Arachnides are subject to such changes. Now, as all Arachnides are essentially distinct from the Crustacea, and as they differ from insects in the important characteristic just mentioned, it follows, according to M. Lamarck, that they constitute an assemblage of beings which ought not to be held in separation, however diversified they may be in various points of their organization.

The most remarkable circumstances in the structure of Arachnides are the following: That while many of these creatures are obviously provided with a circulating system, others present no vestige of that system; that the former breathe by means of branchial cells, while the latter respire through tracheæ; and that certain tribes are provided with antennæ, and others are entirely destitute of any such organs. These apparent non-conformities of structure result from this, that throughout the extended course of their class, the organization of the Arachnides undergoes rapid and remarkable changes; and if in the course of our observations we were to attend not only to the differences of external or internal parts, but to the progress of nature in the order of her productions, we would sooner perceive the propriety of that succession or change of organization even among animals really allied to each other by the great majority of their relations; and it would not have been deemed necessary to remove to another class such of the Arachnides as were antennated, because it would have been then more clearly perceived how incompatible was such a change with the assignment of their natural and appropriate place in the system.

[1] See the *Histoire Naturelle des Animaux sans Vertèbres*, 7 vols. 8vo. Paris, 1815–22.

[2] "Animalia ovipara, pedibus articulatis in omni tempore instructa, ad metamorphoses non subjecta, nec nova partium genera acquirentia. Respiratio trachealis aut branchialis: orificiis pro aeris intromissione stigmatiformibus. Cor circulatioque in pluribus inchoatis. Copulationes," &c. *ut supra*.

The class of Arachnides, as established by Lamarck in his *Cours*, contained five or six small families, which, though each possessed of particular characters of distinction, it would have been difficult to separate from their common frame-work, without considerable inconvenience to whatever other class one or more of such families might have been removed. If, for example, the antennated Arachnides should be classed among insects, we then destroy the most simple and satisfactory definition which can be given of the last-named class, while we are forced to assign to the animals with which we unite them a position in the general series unsuitable to their real nature and attributes. If we transport the tracheal Arachnides to the class Insecta, in order to enable us to define the latter class by the exclusive character of respiring by tracheæ, then insects can no longer be said to be uniformly distinguished by the possession of antennæ, and the genus Phalangium, &c. would be separated from the class which contains the spiders. For these reasons Lamarck is of opinion that the division which contains his Arachnides, whether antennated or non-antennated, ought to be preserved in its integrity, if we wish to avoid the impropriety of associating with insects other forms of animal life which nature has distinguished by different characters.[1]

A class may be constituted of natural materials, and contained within suitable limits, and nevertheless present among its various families animals of very different forms and construction. During every period of its existence, a butterfly presents an aspect very dissimilar to that of a scarabæus, yet both belong to the true Insecta. When strong general affinities (*analogies d'ensemble*) prevail, those special diversities of structure which are occasionally observable are insufficient to authorize a separation of classes. The genera Aranea, Phalangium, and Galeodes, are very nearly related to each other, although the first respire by obvious branchial cells, while the others enjoy a tracheal respiration.

The non-antennated Arachnides are in general provided with eight feet; and the Acarides and Pycnogonides conduct naturally to the Phalangides, such as the genus phalangium and others. Now, if these Acarides belong essentially to the Arachnides, can the parasitical genera, such as Pediculus and Ricinus, which lead towards them so evidently, be regarded as belonging to another class? The transition is so gradual and prepared, that the Acarides, provided for the most part with eight feet, like the other non-antennated Arachnides, yet present us with many genera (such as Astoma, Leptis, Caris) which have never more than six. Lamarck maintains the necessity of preserving the class Arachnides according to the limits which he has himself assigned to it, because its being so preserved relieves the class of insects from species with which that class has little or no connection. Without citing the impossibility of assigning a suitable position among insects to tribes like the Parasites, the Thysanoura, and the Myriapoda, the strongest objection to the reunion of these animals with insects is, that it will alter the general and truly natural characters assigned to the latter, viz. that of presenting, after exclusion from the egg, a particular state of *larva*, singularly varied according to the different orders in the forms and parts of the animal, and that of finally exhibiting an *imago* or perfect state very different from the larva, and distinguished by six articulated legs, two reticulated eyes, and a pair of antennæ.

Arachnides, on the contrary, although in many instances antennated, and, like all other living beings, undergoing successive developments of parts from the period of their birth, yet offer not the condition of a larva distinct from that of the perfect state: they preserve, not of course the dimensions, but the form and proportions of the parts with which they were originally produced; and if a few of them acquire additional parts in the course of their development, these are not of a new kind, but merely supernumerary to such as previously existed; for example, a pair of feet, or another segment to the abdomen. But this kind of development is different from that called metamorphosis in insects. All of these acquire either a new form, or parts of structure of a different kind from those which they possessed when first produced from the egg; and their state of larva, manifestly distinct from that of the perfect insect, is never equivocal.

Thus the Arachnides of Lamarck, distinguished in a general point of view from true insects by the want of metamorphoses, yet breathing in air, are remarkable for the singular gradations which their organization presents us when we compare the different families with each other. In fact, these animals exhibit, in their totality, different groups, which offer among themselves such great dissimilarities of organization, as might almost furnish the materials of as many classes; but such a proceeding would injure the simplicity of systematic arrangement, and would be unsuitable, in as far as these great divisions might still be connected together by characters of general application, the same, in truth, as those by which the class of Arachnides is itself distinguished.

Although certain Arachnides possess organs adapted to a circulating system, they do not on that account belong to the crustaceous class. They are chiefly distinguished from that class by their respiratory organs, which, whether tracheal or branchial, are always placed in the interior of the body, whilst in the Crustacea they are external. In the former, also, the opening which admits the fluid to be respired is stigmatiform; but it is not so in the latter.

Even the structure of the eyes affords an index to the Arachnides. All true insects have two eyes, with plane facettes, presenting the appearance of a very delicate network; but in the Arachnides the eyes are smooth, whether isolated, as among the greater number, or grouped as in spiders, and form a small mass, of which the surface is granular or sub-granular, and not in facettes. Arachnides form a class superior to insects, because many of them are more highly organized, and all of them are more nearly allied to the Crustacea than genuine insects. It does not follow from this that all the individuals of that class are superior to the most perfect insects, or that they have derived their existence, according to the French phraseology, by transition from these last-named creatures, or by an advance or progression in the scale of organization. For in the progress of animal life from the lower to the higher groups, the Arachnides appear to commence almost at the same epoch as the genuine insects, and present a dichotomous or double ramification, corresponding in its level with that which bears the entire class of insects. About that same point of the animal kingdom there seems in fact to be three distinct streams or courses of life, immediately succeeding the Epizoaria, viz. that of the apterous insects (*Pulex*), which leads successively to all the other forms of insect life; that of the antennated parasitical Arachnides (*Pediculus* and *Ricinus*), which leads to the Acarides and other non-antennated Arachnides; and that of the wandering (*vagabundæ*) antennated Arachnides (Thysanoura and Myriapoda), from which the crustaceous tribes may be said to spring.[2]

[1] *Animaux sans Vertèbres*, tome v. p. 6.

[2] *Ibid.* tome v. p. 10.

Thus, of those great divisions which appear to derive their origin almost from the same point in the scale, the first is formed of an enormous series of animated beings, characterized by the strongly contrasted aspects of larva and perfect insect; and the others are true Arachnides, and consequently present no such marked distinction between the conditions of the young and old. In the most perfect of the arachnidean class, such as spiders and scorpions, Cuvier has demonstrated a muscular and dorsal heart, subject to sensible systole and diastole; and on the abdomen he discovered several stigmatic openings (from two to eight), which lead to an equal number of particular purse-shaped cavities, each of which contained a great many small and very delicate laminæ or plates. These isolated cavities, and the plates with which they are filled, are without doubt the respiratory organs of these Arachnides. Cuvier regards them in the light of lungs; while Lamarck himself is inclined to view them rather as branchial cavities analogous to those observable in the leech and earth-worm—the property of branchia being, in the first place, the power of becoming habituated to the respiration of air (water being their usual medium), whilst the true lung respires air alone; and, in the second place (and this character applies of course *a fortiori* to lungs also), never to exist except in animals which are possessed of a circulating system.[1]

Finally, from the dorsal heart already mentioned two large vessels derive their origin, and are then ramified over the membrane of the respiratory cavities. Cuvier regards these vessels as pulmonary, the one acting as an artery, the other as a vein—and other vessels spring from the same dorsal trunk, and distribute themselves to various parts of the body. In these animals there is even a liver, composed of four pair of glandular clusters, which discharge their fluid at four different points of the intestine.

It is among the Arachnides that we find the first establishment of organs for the circulation of the animal fluids; and in the same class we perceive, as it were, the termination of tracheal respiration by ramified tracheæ, with a view to the substitution of the branchial system, which, though in itself admitting of considerable variation, is always characterized by its more local restriction. Among the Arachnides also we find the commencement of the principal of the conglomerated glands.

The respiratory sacks, which Cuvier pointed out in the spiders and scorpions, were also detected by M. Latreille in the genus Phryna, in such a manner as to connect, by that dominating feature in their structure, the Arachnides *pedipalpes* and the Arachnides *fileuses* of that author. Although among the Phalangides the respiratory sacks have not yet become perceptible, yet the aeriferous tracheæ have changed their character, and no longer consist of a double cord with a series of plexus, but are merely branched or ramified. The same order prevails among the Acarides, and results mainly from the reduced number and altered position of the stigmata. Among the antennated Arachnides, in which the stigmata are more numerous, and in general lateral, the tracheal cords, like those of insects, have as many plexus as stigmata; and such Arachnides, in fact, approach the most nearly to the class of insects. Thus tracheal respiration changes by degrees its nature and mode of action, as the stigmata undergo an alteration in regard to their number and position; and, becoming more and more reduced and restricted, it prepares the way, as it were, for branchial respiration, which only shows itself effectively along with the establishment of a circulating system. It results from these considerations that, in spite of the difference of organization observable in different families of Arachnides, these families are nevertheless related and united by natural affinities, which it is impossible to mistake, and would be improper to separate, and which appear to place them at an almost equal distance from Insects and Crustacea. In their aspect, however, they in general resemble somewhat more nearly the latter class. For example, the cancerides or crabs represent in some respects, by their short bodies, and heads confounded with the thorax, the usual form of spiders; while the cray-fish and Thalassinæ (*Cancer anomalus*, Leach) recall the figure of the scorpion.

The greater proportion of Arachnides dwell on the land, a few inhabit the waters, and a certain number are parasitical on the bodies of other animals, of which they suck the juices. In general they are carnivorous, and live on blood, or at least on animal substances; a very limited number existing on vegetable matter. Many are furnished with mandibles, which perform the functions of a trunk or sucker; and others are provided with an isolated or separate trunk, frequently accompanied both by mandibles and palpi. They are for the most part solitary animals, of gloomy habits, and forbidding aspect; they court concealment, and avoid exposure to strong light. The bite of many species is dangerous, in consequence of a poisonous or irritating fluid frequently instilled into the wound. The offensive organ in the scorpionides is placed at the extremity of the abdomen.

The following is a tabular view of M. Lamarck's system of arrangement.

General Division of Arachnides.

Order I.—*Antennated tracheal Arachnides.* Head furnished with two antennæ. Respiration effected by means of double-corded plexiform tracheæ.

Section I.—*Crustaceous Arachnides.* Two composite eyes, of which the surface is granular or sub-granular. They are sometimes called wandering Arachnides, to distinguish them from such as are fixed or parasitical. They are frequently of a scaly structure, and provided with mandibles fitted for incision and division. This section consists of two families, viz. *Thysanoura* and *Myriapoda*. The following are the genera of *Thysanoura:* Smynthurus, Podura, Machilis, Lepisma. Those of *Myriapoda* are, Scutigera, Lithobius, Scolopendra, Polyxenus, Julus, Glomeris.

Section II.—*Acarideous Arachnides.* Two or four smooth eyes. These animals are parasitical, and provided either with a retractile sucker or with two mandibles hooked for the purpose of adhesion. Their bodies are never scaly. The genera are Pediculus and Ricinus.

Order II.—*Non-antennated tracheal Arachnides.* No antennæ. Tracheæ for respiration branched, but not ganglionized. Two or four smooth eyes.

Section I.—Body either without apparent division, the head, thorax, and abdomen, being united in one mass, or composed of two divisions. This section is composed of two families, viz. *Acarides* and *Phalangides.* The former contains the following genera: Astoma, Leptus, Caris, Ixodes, Argas, Uropoda, Smaris, Bdella, Acarus, Cheyletus, Gamasus, Oribata, Erythræus, Trombidium, Hydrachna, Elais, Limnochares. The

[1] *Analyse des Travaux des Sciences de l'Institut pendant l'année* 1810.

genera of *Phalangides* are these—Trogulus, Siro, Phalangium.

Section II.—Body divided into three or four distinct segments. This section is likewise composed of two families, *Pycnogonides* and *Pseudo-scorpiones*. Of the first family the genera are, Nymphum, Phoxichilus, Pycnogonum; of the second, Galeodes, Chelifer.

Order III.—*Non-antennated branchial Arachnides.* No antennæ. Branchial cells or pouches for respiration. From six to eight smooth eyes.

Section I.—*Pedipalpi* or *Scorpionidæ*. Palpi very large, in the form of projecting arms, terminated by claws or pincers. Abdomen distinctly ringed, and not furnished with a spinning apparatus. Genera—Scorpio, Thelyphonus, Phrynus.

Section II.—*Araneides* or *Spinning Arachnides.* Palpi simple, in the form of small feet; those of the male bearing the sexual organs. Mandibles terminated by a movable crotchet. Abdomen without rings, and furnished at its termination with a web-making apparatus, consisting of from four to six spinners. Genera—Aranea, divided into numerous tribes or sub-genera; Atypus, Mygale, Avicularia.

In his *Considérations Générales*, M. Latreille founds the orders of the class Arachnides on two principal points as the first basis. These animals are either masticators or suckers. The jaws of the former are simple, and fitted for cutting and triturating the substances on which they feed; those of the latter, when they exist at all, serve only to seize their prey, and are terminated by a movable piece, either solitary and hooked, like a claw or crotchet, or accompanied by a fixed projection like a small finger. In the latter case the mandibles have the appearance of a pair of pincers. The Arachnides of this division compress with their pincers the small animals on which they prey, and so force the alimentary juices to pass by degrees into the œsophagus. The body of their prey having undergone this operation, is thrown aside. In spiders the claw of the mandible seems to execute an additional function. It distils a poisonous liquid, analogous in its nature to that which exudes from the mouth of the scolopendra, and the tail or sting of the scorpion. Moreover, all the masticating Arachnides are furnished with antennæ, while the suctorial tribes, with the exception of two genera, Ricinus and Pulex, are unprovided with these organs. Thus the primary divisions of this class by Latreille nearly correspond to Lamarck's two orders, the *Antennistes* and *Palpistes*.

M. Latreille then subdivides the masticating Arachnides into three orders—*Tetracera, Myriapoda*, and *Thysanoura*. The last alone present a thorax distinct from the abdomen, and have no more than six feet. In the two first-named orders the organs of movement amount at least to the number of fourteen, disposed along the sides of the body, each segment of which, with the exception at most of the last three, carry one or two pair. The Tetracera (genus *Oniscus* of Linnæus) are distinguished by four antennæ; there are only two in the Myriapoda. The Tetracera have besides several jaws, and are furnished with plates or foliaceous appendages on the inferior surface of the posterior extremity of their bodies The number of their feet is invariably fourteen. They are related in several particulars to the Crustacea. De Geer observed, that in Assellus and Idotea there is a kind of membranous cavity, frequently filled with air, beneath the plates of the tail; and similar parts are observable in the true crustaceous Squillæ of Fabricius. In Oniscus the air penetrates the body by openings, which are covered by the first folds of the tail. The other Tetracera probably receive it in a similar manner: at all events they are not provided with distinct external stigmata, like the Arachnides of the succeeding orders. We still find in this first division species which inhabit the sea; but as soon as we enter the order Acera (scorpions, spiders, &c.) we find none occurring in that element.

The structure of suctorial Arachnides is reducible to three principal forms or combinations of organs; 1*st*, Those possessed of antennæ, and of which the head is distinct from the thorax—*Parasita;* 2*d*, Those which are unprovided with antennæ, each segment of the body furnished with a pair of legs, and the head distinct—*Pycnogonides;* 3*d*, Those which are unprovided with antennæ, but of which the head and thorax are confounded as it were in a single segment, which alone is provided with feet—*Acera*. This last-mentioned order, according to Latreille, would form the first, if the organs of the mouth alone were considered, as these are more complicated than in any other suctorial Arachnides. The Acera have two palpigerous maxillæ, and frequently a lip, with two strong mandibles. The generality of the Pycnogonides have also mandibles, which have been taken for palpi, and true palpi, which have been erroneously regarded as antennæ; but their mouth consists of a tunnel or syphon of a single piece. It is still more simple in the Parasites, being nothing more than a very short projection, containing a small sucker, or a cavity of which the sides are dilatable, and accompanied by two crotchets.

In regard to the *families* of the Arachnides, the Tetracera offer two principal groups. Some dwell in salt or fresh water, are usually fixed upon other animals, of which they suck the blood, and have, with the exception of the genus Bobyra, four very obvious and distinct antennæ. They constitute the first family, that of *Asellota*. Others are more terrestrial than aquatic. They wander from place to place, love obscure and sombre situations, and live upon putrid substances; their two intermediate antennæ are but slightly developed. They form the second family, called *Oniscides*. According to Latreille, the structure of the mouth in Scolopendra is so different from that of Julus, that it is difficult to conceive the motive which influenced Fabricius to unite these Arachnides into a single order, that of *Mitosata*. In Julus, the maxillæ and the lip are soldered together, forming one transverse plate, without distinct palpi, or their place supplied by tubercles. The Scolopendræ have their maxillæ separated, four projecting palpi, and the labia in the form of hooks, subservient to the same uses as the mandibles of spiders. These considerations, and the figure of the antennæ, have required the establishment of two families, which compose Latreille's order Myriapoda, viz. *Chilognatha* and *Syngnatha*. Proceeding upon the same principles, he divides the order Thysanoura likewise into two families, the *Lepismenæ* and the *Podurellæ*. The next orders, Parasita and Pycnogonides, contain few genera, and do not admit of subdivision into families. The last order, Acera, is composed of eight families, viz. Scorpionides, Pedipalpi, Aranides, Phalangita, Acaridiæ, Riciniæ, Hydrachnellæ, and Microphthira.

Before commencing our systematic exposition of this class, we shall lay before our readers the sentiments of Mr Kirby. "I must next say something on the orders of the Arachnida. Every one at first sight sees that *spiders* and *scorpions* are separated by characters so strongly marked, that they look rather like animals belonging to different classes, than to the same. These form the two primary orders of the *Arachnida*, and they appear to be connected by two secondary or osculant ones,—on the one side by *Galeodes*, and on the other by *Thelyphonus* and *Phrynus*. This class, although there is an appearance of

eight legs, is, strictly speaking, of a *Hexapod* type; for the anterior pair, ordinarily regarded as legs, and performing their function, are really the analogues of the maxillary palpi of perfect insects. This will be evident to you if you examine any species of *Galeodes*. These animals, if we look at them cursorily, we should regard as decapods; but when we trace the two anterior pairs of apparent legs to their insertion, we find that both proceed from the *head*, which in that genus is distinct from the trunk; while the three last pairs, which alone are furnished with claws, are planted, as legs usually are, in the latter part. The first pair represent the ordinary palpi of *Arachnida*, are analogous to the labial ones of hexapods, and, as likewise in Phrynus and Thelyphonus, are more robust than what are usually taken for the first pair of legs; but they differ in being considerably longer, and, instead of terminating in a *chela*, are furnished with a retractile sucker.[1] The second pair are more slender and shorter than the first. They correspond precisely with what are deemed the first pair of legs of *Octopods* and *Arachnida*, and are clearly analogous to the maxillary palpi of insects. Whether the base of the first pair of these palpi is in any respect analogous to the labium of insects (as that of the second seems to be to their maxillæ), I am not prepared to assert; it will therefore be most advisable to name these palpi *anterior* and *posterior*; but as they evidently proceed from the head in Galeodes, and in that genus are clearly analogous to those of the Phrynidea (which in their turn as clearly represent those of the Aranidea), it follows, that in all they are organs of the part representing the head, and therefore not in a *primary* sense *legs*, although in a *secondary*, as M. Savigny[2] has proved, they may be so called."[3]

The following are the secondary groups of the class Arachnides, according to Mr Kirby's exposition, in the work last quoted.

1. Aranidea.—M'Leay. (*Aranea*, L., *Araneidæ*, Lat.) The Aranidea or spiders seem resolvable into two sub-orders—the *Sedentaries* and the *Wanderers;* thus forming, perhaps, what Mr M'Leay would denominate the normal groups of a circle of *Arachnida*.

   Def.—*Mandibles* armed with a perforated claw. *Head* and *trunk* coalite. *Palpi* pediform, anterior pair without claws. *Abdomen* without segments or elongated tail. *Spiracles* two. *Anus* furnished with an apparatus for spinning.

2. Scorpionidea.—M'Leay. (*Scorpio*, L. Latr.)

   Def.—*Mandibles* chelate. *Head* and *trunk* coalite. *Anterior palpi* chelate. *Posterior palpi* pediform. *Pectens* two. *Abdomen* divided into segments, and terminating in a jointed tail, armed at the end with a sting. *Spiracles* four pair.

3. Galeodea.

   Def.—*Head* distinct. *Eyes* two. *Mandibles* chelate, with dentated chelæ. *Palpi* pediform, the anterior pair thickest, with a retractile sucker. *Trunk* consisting of two principal segments, with a minute supplementary posterior one. *Spiracles* two, placed in the trunk. *Pseudo-pectens* two. *Abdomen* divided into segments. *Anus* unarmed, and without a spinning apparatus.

4. Phrynidea.

   Def.—*Mandibles* unguiculate. *Anterior palpi* chelate or unguiculate, very robust. *Posterior palpi* pediform, very long and slender. *Abdomen* divided into segments. *Spiracles* two pairs. *Anus* terminating in a mucro, and sometimes in a filiform jointed tail, without a sting at the end.[4]

In the *Règne Animal* (2d edition, 1829), Latreille includes in the class Arachnides only those species which correspond to the *Arachnides palpistes* of M. Lamarck. By this arrangement he is of opinion they may be classed and defined in a more simple and rigorous manner. According to his most matured views, then, the Arachnides, like the Crustacea, are destitute of wings, and are not subject to metamorphoses, but only to simple changes. Their sexual organs are removed from the posterior extremity of their bodies, and situated, with the exception of certain males, at the base of the abdomen. They bear a resemblance to insects in as far as the surface of their bodies present openings or transverse clefts named *stigmata*, for the entrance of air, but in smaller number than in insects (eight at most, generally two), and placed only at the inferior part of the abdomen. Their respiration is farther carried on either by aerial branchia, performing the office of lungs, inclosed in the cells of which the openings just mentioned are the entrance, or by means of radiated tracheæ. The organs of vision consist of small simple eyes, variously grouped when numerous. The head, usually distinct from the thorax, presents, as analogous to the antennæ of insects, two articulated appendages, in the form of small talons of two or more pieces, which have been improperly compared to the mandibles of insects, though moving in a different direction. They, however, cooperate in the action of the jaws, and are represented in those Arachnides of which the mouth is formed like a syphon or sucker by two pointed plates or lancets.[5] A sort of lip (*labium*, Fab.), or rather tongue, formed by a pectoral prolongation; two maxillæ, formed by the radical part of the first article of two small feet or palpi,[6] or by a lobe or appendage of that article; a beak-shaped projection, named sternal tongue (*langue sternale*) by M. Savigny, produced by the re-union of a very small chaperon, terminated by a minute triangular lip, and of a longitudinal inferior keel, usually hairy:—these, and the parts called mandibles, compose, under certain modifications, the general structure of the mouth in the class Arachnides. The pharynx is placed in advance of a sternal projection, which has been regarded as a lip; but when we consider its position behind the pharynx, and the absence of palpi, it is probably rather analogous to a tongue (*languette*). The feet, like those of insects, are generally terminated by two crotchets, sometimes by three, and are all attached to the thorax, which is almost always formed of a single articulation, for the most part intimately united to the abdomen. The abdomen in the greater proportion of species is soft, or but slightly protected.

When considered in relation to their nervous system, the Arachnides are obviously distinguished both from the Crustacea and Insects; for, with the exception of the scorpions, the ganglia or swellings of the nervous cords never exceed three in number.

The greater proportion of Arachnides feed on living insects, the bodies of which they seize or adhere to, and

[6] According to Latreille, these do not differ from feet properly so called, except in the tarsi, composed of only a single joint, and usually terminated by a small crotchet; they almost entirely resemble the ordinary feet of the Crustacea

suck their juices. Others are parasitical on the bodies of vertebrated animals. A few, such as certain mites, feed on cheese, and on flour and other vegetable productions. In some of the species two of the feet are not developed till the animals have changed their skin; and in general it is not till after their fourth or fifth moult, or casting of their exuviæ, that the Arachnides attain to their completed state.[1]

The following tabular view exhibits the classification and relative position of the orders and genera of this extensive class.

CLASS ARACHNIDES.

ORDER I.—PULMONARIÆ.

FAMILY I.—ARANEIDES.

SECT. I.—*Tetrapneumones.*

Genus 1. Mygale.
2. Cteniza.
3. Atypus.
4. Erodion.
5. Dysdera.
6. Filistata.

SECT. II.—*Dipneumones.*

A.—Sedentariæ.

Tribe 1.—*Tubitelæ.*

Genus 7. Clotho.
8. Drassus.
9. Segestria.
10. Clubiona.
11. Aranea.
12. Argyroneta.

Tribe 2.—*Inæquitelæ.*

Genus 13. Scytodes.
14. Theridion.
15. Episinus.
16. Pholcus.

Tribe 3.—*Orbitelæ.*

Genus 17. Linyphia.
18. Uloborus.
19. Tetragnatha.
20. Epeira.

Tribe 4.—*Laterigradæ.*

Genus 21. Micrommata.
22. Senelops.
23. Philodromus.
24. Thomisus.

B.—Erraticæ.

Tribe 5.—*Citigradæ.*

Genus 25. Oxyopus.
26. Ctenus.
27. Dolomedes.
28. Lycosa.
29. Myrmecia.

Tribe 6.—*Saltigradæ*

Genus 30. Tessarops.
31. Palpimanus
32. Eresus.
33. Salticus.

FAMILY II.—PEDIPALPI.

Tribe 1.—*Tarentulæ.*

Genus 34. Phrynus.
35. Thelyphonus.

Tribe 2.—*Scorpionides.*

Genus 36. Buthus.
37. Scorpio.

ORDER II.—TRACHEARIÆ.

FAMILY I.—PSEUDO-SCORPIONES.

Genus 38. Galeodes.
39. Chelifer.

FAMILY II.—PYCNOGONIDES.

Genus 40. Pycnogonum.
41. Phoxichilus.
42. Nymphon.
43. Ammothea.

FAMILY III.—HOLETRA.

Tribe 1.—*Phalangita.*

Genus 44. Phalangium.
45. Gonoleptes.
46. Siro.
47. Macrocheles.
48. Trogulus.

Tribe 2.—*Acarides.*

Genus 49. Trombidium.
50. Erythræus.
51. Gamasus.
52. Cheyletus.
53. Oribata.
54. Uropoda.
55. Acarus.
56. Bdella.
57. Smaridia.
58. Ixodes.
59. Argas.
60. Eylais.
61. Hydrachna.
62. Limnochares.
63. Caris.
64. Leptus.
65. Aclysia.
66. Astoma.
67. Ocypete.

We shall now proceed to the first subdivision of the class into two great orders.

ORDER I.—ARACHNIDES PULMONARIÆ.

Characterized by the possession of pulmonary sacks, a heart with distinct vessels, and from six to eight simple eyes. The sacks contain aerial branchia, which perform the office of lungs, and are named pneumo-branchia by Latreille. They are placed under the abdomen, and are indicated externally by *stigmata* or small transverse openings, of which there are sometimes four on each side, sometimes only four in all, or two on each side. The eyes vary in number from six to eight,[2] whereas in the subsequent order (*Trachearïæ*) there are never more than four. The respiratory organ is formed of small plates. The heart is a

[1] Latreille has observed, in conformity with the experience of Jurine *fils*, that the *Argulus* of Müller does not acquire the faculty of generating till after the completion of the sixth moult. Caterpillars generally change their skins four times before they assume the form of the chrysalis, which, with the final transformation to the perfect state, causes the number of moults to amount also to six.

[2] The genus *Tessarops* of M. Rafinesque is described as having only four eyes; but M. Latreille is of opinion that the lateral pair had been overlooked.

large vessel, which stretches along the back, and gives off branches forwards and on either side.[1] The feet are constantly eight in number. The head is always confounded with the thorax, and presents two pincers (*mandibulæ* of authors, *chelicères* or *antenne-pinces* of Latreille) terminated by two finger-like projections, of which one is movable, or by a single hook or claw, always movable. The mouth is composed of a lip (*labium*); of two palpi, which sometimes assume the shape of arms or talons; of two or four maxillæ, formed, when there is only a pair, by the radical article of the palpi, and when there are four, by that same article and the corresponding portion of the first pair of feet; and of a languette of one or two pieces. If we were to assume as a basis the progressive diminution in the number of the pulmonary sacks and stigmata, then the scorpions which have eight, while the other Arachnides have only four or two, would form the leading genus of the class, and the family of *Pedipalpi* would take precedence of the *Araneides* or spinners; but these last-named Arachnides are to a certain extent isolated, by reason of the sexual organs of the male, by the hook of their frontal talons, by their pediculated abdomens, and the peculiarities of their spinning apparatus, as well as by their natural habits; and the scorpions also appear to form a more natural transition from the pulmonary Arachnides to the family of the pseudo-scorpions, the first of the second order.

Of all the Arachnides the *Pulmonariæ* exhibit the greatest analogies to the crustaceous class, especially to the genus Limulus and others of the pæcilopodous order. The pneumo-branchia and their stigmatiform openings may frequently be detected externally by yellowish-white markings, disposed in two longitudinal series. The first two are placed immediately beneath the sexual organs, at least in the females, at a small distance from the origin of the abdomen, and on its second segment, when that part is annular or divided into segments. Thus the second segment in these Arachnides corresponds in its characters to the first segment of the female Limulus. We may also perceive in them the indications of conglomerated glands, and even in certain species traces are observable of chiliferous vessels.

The claw of the mandibles in spiders, and the terminal joint of the tail in scorpions, form a species of dart, perforated by one or two openings, which give issue to a poisonous liquid secreted by special glands. This poison is mortal to such small creatures as form the natural prey of the Arachnides, and is even productive of dangerous consequences to man and the larger animals. Its mode of action on animals unprovided with a circulating system is not clearly understood, but the phenomena attending it might reasonably be adduced in support of that theory which advocates the agency of poison from the bite of venomous reptiles as being carried on as much through the medium of the nervous as the circulating fluid. The almost instantaneous death of animals from the bite of certain snakes has been regarded as a proof that the vascular system was not alone concerned; and the same sudden effect produced upon those classes in which, as far as we can perceive, no vascular system exists, demonstrates some other mode of action.

Notwithstanding the researches of Cuvier, Marcel de Serres, Leon Dufour, Treviranus, and other observers, our knowledge of the internal organization of several genera of Arachnides is extremely deficient. Hence it is difficult to trace the boundaries of the orders in a manner at once natural and precise. At the same time it has been remarked, that the accurate observation of the eyes and other external organs furnish characters which coincide with the distinctions deduced from internal structure, as far as the latter has been ascertained.

Family I.—Araneides.

This extensive family corresponds to the genus Aranea of Linnæus, and contains all those species commonly called spiders—the *Arachnides fileuses* of Latreille. The characters are, two or four branchial pouches; from six to eight simple eyes; last article of the mandibles (*chelicères*) in the form of a corneous claw, perforated at the extremity for the emission of poison, and folded upon the preceding joint; abdomen usually soft, without divisions, its extremity furnished with from four to six small teat-like appendages, pierced with numerous holes for the passage of the silk or spinning materials;[2] feet palpi, without pincers at the extremity, but terminated in the female by small hooks, and in the male by the generative organs. The maxillæ are never more than two in number. The languette consists of a single piece, always external, and placed between the maxillæ; its form more or less square, sometimes triangular or semicircular. The thorax, usually impressed with a form resembling the letter Y, indicating the space occupied by the head, is composed of a single article. The legs, of which the forms are analogous, though the dimensions differ considerably, are composed of seven joints, of which the first two form the haunch, the third the thigh, the fourth and fifth the leg, and the remaining two the tarsi; the last is terminated by a couple of hooks, which are usually toothed or pectinated, and in many species there is an additional tooth or smaller size, but not pectinated. The intestinal canal is straight: there is first a stomach composed of several sacks; and towards the middle of the abdomen a second dilatation occurs. According to Marcel de Serres the heart is situated in the abdomen, and stretches throughout its whole length; there is a considerable swelling towards its superior extremity, after which it assumes and retains the cylindrical form. It is very muscular, and its pulsations are strong and frequent. The pulmonary pouches, usually two in number, are always situated on the lower surface of the abdomen, near its origin, and are covered by a coriaceous skin, generally of a red colour; the stigmatiform opening proper to each pouch is placed towards its base, on the inner side. These pouches are formed of a white membrane, strong but flexible, which presents on its interior, transverse, projecting, parallel, nearly semicircular folds or plates, which constitute the respiratory organ. The liver is proper to the abdomen, of which it occupies the chief portion. It is composed of an infinity of minute glands fixed to the intestinal canal, and filled with a peculiar liquid, thick, and of a brown colour. The interior of the abdomen also contains the silk vessels, four in number, long, cylindrical, folded, yellow. They open into a common canal, situated at the origin of the spinners.

[1] According to M. Marcel de Serres (*Mémoire sur le Vaisseau Dorsal des Insectes*), the blood in the araneides and scorpions proceeds first to the respiratory organs, and from thence by special vessels to the various parts of the body. Latreille, however, seems to think, from the relations which exist between these creatures and the crustaceous tribes, that such circulation may be effected in the contrary direction. See the *Règne Animal*, tome iii. p. 212; and a memoir by Treviranus *On the Internal Organization of Arachnides*. 1 vol. 4to, Nuremberg, 1812.

[2] Some naturalists are of opinion that the two small spinners placed in the centre of the four exterior ones yield no silk.

The nervous system consists, 1*st*, of a cerebriform ganglion, placed towards the base of the thorax, quadrangular in some, in others rounded—from it proceed whitish nervous threads to the mouth, eyes, and feet; 2*dly*, of two nervous cords, derived from the above ganglion, which occupy the median line of the body, and of ganglia which distribute nervous filaments to the different organs, and principally to the alimentary canal and the silk vessels. M. Dufour did not ascertain the number and disposition of these latter ganglia. According to Treviranus they do not exceed two.

The dorsal and abdominal region of many spiders exhibit several small depressed points, which are produced by the attachment of the filiform muscles which traverse the liver. These are likewise observable in the scorpions.[1]

The silk vessels with which both sexes of many species fabricate those webs so remarkable at times for their symmetrical form and exquisite delicacy of structure, vary in shape and position according to the habits of the species. The formation by these creatures of skilfully wrought nets for the capture of their prey, is a fact of such every-day occurrence and observation, that we cease to regard it in its proper light, as one of the most admirable and surprising instincts of animal life. According to Reaumur, the silk undergoes its first elaboration in two small reservoirs, shaped like a drop of glass placed obliquely, one on each side, at the base of six other reservoirs in the form of intestines, which lie side by side, and folded six or seven times. The latter derive their origin from a little below the commencement of the abdomen, and proceed to the nipples by a slender thread. It is in the last-named vessels that the silk acquires that greater consistence and those other qualities which render it fit for use. A certain degree of dryness or evaporation seems necessary for the proper formation of the threads; but when the atmosphere is in a favourable condition the requisite change appears to take place almost instantaneously.

Various opinions have been entertained regarding the origin of those white, flaky, filamentous, silky substances which are frequently found floating in the atmosphere during the mornings of spring and autumn. They are called *fils de la vierge* by the French, and Lamarck still maintains the opinion that they are meteoric productions. The results of chemical analysis, as well as of ordinary observation, render it little less than certain that they are produced by small spiders of the genera *Epeira* and *Thomisus*. The innumerable threads which the sun-beams occasionally bring to view over the entire surface of ploughed fields are also formed by spiders of the genus Lycosa. Latreille is of opinion that many of these creatures, before they are sufficiently provided with spinning materials to form webs, content themselves by ejecting simple longitudinal threads. They are merely apprentices to the weaving art.

The habits of spiders vary greatly. Some rest in the centre of their webs, the outstretched cordage of which warns them of the temporary entanglement of their prey, on which they instantly rush, and devour after the infliction of a mortal wound. Others seek the protection of a leaf or other natural harbour, and only appear in the more open parts of their premises when lured by an expected capture. Many spin comfortable tunnels, or horizontal watchtowers, as they may be called, in which they repose till the vibration of their nets calls them into active service. An extensive tribe of erratic species (the *vagabundæ*) spin no webs at all, but trust to strength, activity, and cunning, for their daily, or, it may be, monthly fare; for spiders, though voracious in times of abundance, are capable of frequent and long-continued abstinence. The webless species are often endowed with the faculty of leaping, and after insidiously approaching their prey by the most wary and almost imperceptible footsteps, they spring upon it at once, and inflict the fatal wound. Several kinds hunt down their insect food by speed of foot; and a few are nocturnal, and surprise their defenceless and unsuspecting victims during the darkness of the night. According to Mr Sheppard, a large species, which occurs among the fen ditches of Norfolk, actually constructs a sort of raft of weeds, or floating island, on which it allows itself to be wafted about, and from which it seizes upon drowning insects; and another (*Lycosa piratica* of Walckenaer) gives chase to its prey over the surface of the water.

Unwet they bathe their oily forms, and dwell
With feet repulsive on the dimpling well.

The passion of love, so powerful in its influence over the most savage beasts, rules with a feeble and transitory sway over the subjects of our present inquiry. The male spider approaches the female with the greatest circumspection, fearful lest the sexual feeling should not have banished that thirst for blood which under ordinary circumstances induces them to prey as readily on each other as on winged insects. It therefore not unfrequently happens, that if a small male approaches a large female, whose feelings unfortunately do not coincide with his own, instead of being caressed he is eaten. According to Audebert, the female of the domestic spider is capable of producing successive generations without any renewal of intercourse with the male. He also states that he kept the same individuals in life for five or six years.

All female spiders, including even the erratic and webless species, are provided with reservoirs of silky matter, which, if not used in spinning, are at all events employed in forming a protecting covering for the eggs. The most casual observer of nature must have frequently remarked the care with which the anxious mother carries about and watches over her unhatched offspring; and the delicate colour of the silken bag which contains the eggs, and the fine contrast which in some cases it presents to the body of the parent, cannot have escaped observation. The truth is, that spiders, though frequently of a repulsive aspect, are as often distinguished not only by great beauty of colour, but by extreme elegance of form and delicacy of structure. We are prejudiced against the race in general, because all those that dwell within doors are of a dark and lurid hue, and from their haunts and habits have become objects of aversion and disgust. Thomson has well described,

[1] "L'organe reproducteur du male est formé de deux verges qui s'ouvrent à l'extrémité des palpes, et communiquent chacune avec un testicule en forme de poire, qu'on observe dans le thorax. On voit souvent à coté des verges deux crochets, servant au male à saisir la femelle. L'organe reproducteur de ces derniers individus est placé dans l'abdomen. Il est composé de deux valves, situées vers le milieu de sa partie inférieure, et près de son origine; à leurs deux ouvertures correspondent les oviductus, dont les membranes, en se développant, forment les ovaires. Ces organes ne sont point composés de canaux cylindriques, et ne consistent qu'en une membrane générale, enveloppant tous les œufs, et se divisant seulement vers sa base en deux parties qui se prolongent et constituent les oviductus. On decouvre vers la base des valves un organe particulier, analogue à l'oviscapre des femelles des insectes, coriace, ayant la figure d'un cuilleron, plus large vers son origine qu'à l'extrémité, ou il est assez allongé, et jouissant d'une certaine mobilité. Il parait fournir la matière soyeuse qui recouvre les œufs ou leurs cocons." (*Dict. Class. d'Hist. Nat.* tome i. p. 509.)

Where gloomily retired,
The villain spider lives, cunning and fierce,
Mixture abhorred! amid a mangled heap
Of carcases, in eager watch he sits,
O'er-looking all his waving snares around.
Near the dire cell the dreadless wanderer oft
Passes,—as oft the ruffian shows his front;
The prey at length ensnared, he dreadful darts
With rapid glide along the leaning line;
And fixing in the wretch his cruel fangs,
Strikes backward grimly pleased; the flutt'ring wing,
And shriller sound, declare extreme distress,
And ask the helping hospitable hand.

But many of those which live in fields, woods, and gardens, are worthy of being admired for their beauty, no less than for their singular instincts and remarkable modes of life.

The external appearance varies considerably in the same species, according to the age of the individual. The younger they are, the less varied is their colouring. The number and colour of the eggs differ according to the species. There is seldom more than a single laying of eggs in each year. In some species the eggs are free or unattached in the cocoons which contain them, in others they are fixed by agglutination. In the course of the summer season they are usually hatched in from fifteen to thirty days, according to the temperature. The eggs of such as deposit in autumn (as *Epeira diadema*, a fine species, which occurs in gardens, near the outskirts of woods, and in moors and furzes) are, however, seldom hatched till the commencement of the ensuing spring.

Some species of spider appear to possess the power of reproducing lost or mutilated parts, after the manner of the Crustacea. It is somewhere remarked, that in proportion to the simplicity of organic structure in an animal, its body is more capable of repairing by reproduction such portions as have been destroyed or deteriorated. This would induce the belief that frogs and lizards are lower in the scale than insects, and that the latter, which do not possess the reproductive power, are more highly organized than spiders and other Arachnides. This, however, is not the case; and we may therefore infer that the principle itself is erroneous, or at least incapable of general application. The ascertainment of the fact, that spiders were capable of effecting this repair of parts, is due to the ingenious observations of MM. Vincent Amoreux and Amédée Lepelletier. It was also, however, observed by Sir Joseph Banks in this country, and communicated by him to Dr Leach, by whom the circumstance was recorded in the Supplement to the sixth or preceding edition of this work.

As Sir Joseph was writing one evening in his study, a web-spinning spider, above the medium size, passed over some papers on the table, holding a fly in its mouth. Surprised to see a spider of this description walking about with its prey, and struck with something peculiar in its gait, he caught and placed it under a glass for examination, when he perceived, that instead of eight legs, it had only three. This mutilation accounted sufficiently for its inability to spin a web; but the singular circumstance of its having changed its natural habits, and having become a hunting instead of a spinning spider, and his desire to ascertain whether its limbs would be reproduced, induced Sir Joseph to prolong its captivity. On the following morning the creature destroyed two flies by sucking out their juices, leaving the bodies entire. Two or three days afterwards it devoured the body and head of a fly, leaving only the wings and legs. After this time it sometimes sucked and sometimes swallowed the flies.

Soon after its confinement it attempted to form a web on the side of the vessel, but performed the operation very slowly and awkwardly, owing to the want of the proper number of legs. However, in the course of about a fortnight it had completed a small web, upon which it generally sat, and no doubt regarded with complacency. A month after being caught it shed its skin, leaving the slough on the web. After this change five new legs began to appear, which for a short period were of little or no use to it in walking. These new members, however, extended themselves considerably in the course of three days, and became about half as long as the old ones. The web was now increased, and the spider continued immovably sitting on it in the day-time, unless drawn from it, or attracted by a fly thrown to it as its usual provision. Twenty-nine days afterwards it again cast its skin, leaving the slough hanging in the web, opposite to a hollow cell it had woven so as to prevent itself from being completely seen. The legs were now larger than before the change of the skin, and they continued to increase for several days, but did not attain the size of the old legs. It was then put into a small bowl as a more commodious and convenient residence, where it spun a larger and more perfect web. We are not acquainted with the result of any further observations on the subject.

Various attempts have been made at different periods to fabricate gloves and stockings from the silk of the spider. Nearly a century ago, Bon of Languedoc succeeded in making a pair of each of these articles from this frail material: they were nearly as strong as those of common silk, and of a fine gray colour. Reaumur was appointed by the Royal Academy to report on the advantages which might result from the regular prosecution of a manufactory from spider-silk; but his opinion was, that the natural fierceness and voracity of spiders rendered them entirely unfit to be bred and brought up together. From 4000 to 5000 were distributed in cells, each containing from 50 to 200 individuals; but in a short time only a few were left alive. He also stated, that the web of the spider was not equal to that of the silk-worm, either in strength or lustre. The cocoons of the latter weigh from three to four grains, so that 2304 worms produce a pound of silk. But the bags of a spider, when cleaned of filth and dust, do not weigh above the third part of a grain, so that the work of twelve spiders does not exceed that of a single silk-worm, and to form a pound of silk 27,648 spiders would be required; and as it is the females alone that spin the bags, if they are kept in pairs for the purpose of breeding, 55,296 individuals would be necessary to the formation of every pound. Even this calculation applies only to good spiders of the domestic breed, for those found in gardens scarcely yield the twelfth part of silk of the house species; therefore 280 would not produce more than a single silk-worm, and 663,555 would scarcely yield a pound of silk.[1]

Sir George Staunton, in his *Embassy to China*, states that spiders' webs are met with in the forests of Java of so strong a texture as to require to be cut through with a knife; and in the *Philosophical Transactions* (1668) we are informed that the spiders of Bermudas suspend their webs between trees seven or eight fathoms distant, and that they are so strong as to entangle birds as large as thrushes. "The web of a house-spider," observe Messrs Kirby and Spence, "will, with occasional repairs, serve for a considerable period; but the nets of the geometric spiders are in favourable weather renewed, either wholly, or at least their concentric circles, every twenty-four hours,

[1] *Memoirs of the Academy*, 1710.

even when not apparently injured. This difference in the operations of the two species depends upon a very remarkable peculiarity in the conformation of their snares. The threads of the house-spider's web are all of the same kind of silk, and flies are caught in them from their claws becoming entangled in the fine meshes which form the texture. On the other hand, the net of the garden spider is composed of two distinct kinds of silk; that of the radii not adhesive, that of the circles extremely viscid. The cause of this difference, which, when it is considered that both sorts of silk proceed from the same instrument, is truly wonderful, may be readily perceived. If you examine a newly formed net with a microscope, you will find that the threads composing the outline and the radii are simple, those of the circles closely studded with minute dew-like globules, which from the elasticity of the thread are easily separable from each other. That these are in fact globules of viscid gum, is proved by their adhering to the finger, and retaining dust thrown upon the net, while the unadhesive radii and exterior threads remain unsoiled. It is these gummed threads alone which retain the insects that fly into the net; and as they lose their viscid properties by the action of the air, it is necessary that they should be frequently renewed."[1]

Dr Lister was of opinion that spiders possessed the power of again withdrawing their webs within their bodies,—a fact which, with Degeer, we may reasonably doubt, when we consider the immediate atmospheric change which takes place in the nature of the thread after it is once protruded. In fact, when a spider ascends on the same cord by which it had previously dropped from a height, a small ball or rounded web will be found adhering to it, composed of the coil which it has collected in its re-ascent. The extreme tenuity of the component or elementary threads of the spider's web has been well explained by Leeuwenhoeck. He states that the threads of the minutest spiders, some of which are not equal in bulk to a grain of sand, are so fine that four millions of them would not exceed the thickness of a human hair. Now we know that each spinner, of which there are four, is pierced by about a thousand holes, consequently that every compound or ordinary thread is composed of 4000 still finer. Thus a spider's thread, of the thickness of a human hair, may in some instances be composed of not fewer than *sixteen thousand millions* of single threads!

The bite of an ordinary spider occasions almost instant death to most insects. The great species of South America attack vertebrated animals, such as humming-birds and young pigeons, and their bite is often attended with dangerous consequences even to the human race. Spiders are themselves preyed upon by birds; and a winged insect of the genus *Sphex* pierces them with its sting, carries them off, and buries them dead or alive in holes where its eggs are deposited, the larvæ produced from which afterwards feed upon the dead body of the spider. Most species perish about the commencement of winter, although many others are known to exist for several years. According to Sparmann, they form an article of food to the Bosjiesmen of Southern Africa; and Labillardiere relates, that the inhabitants of New Caledonia eat with avidity great quantities of a spider nearly an inch long (*A. edulis*), which they roast over the fire.[2]

The ascent of spiders into the air, and the extension of their webs from tree to tree across an open space, or even over a running stream, have frequently excited the attention of naturalists. Dr Lister relates, that attending minutely to a spider at work weaving its net, he observed it suddenly desist, and, turning its nipples to the wind, dart out a thread with the violence of a water jet. This thread, taken up by the wind, was carried to some fathoms' length, still issuing from the body of the animal. Some time after the spider leapt into the air, and the thread mounted her up swiftly. He afterwards made the same observation on about 30 other species of spiders, and found the air filled with young and old sailing on their threads, and probably seizing insects in their passage, as he found legs and wings, and other manifest signs of slaughter, on these threads, as well as on the webs below. These observations were corroborated by Dr Hulse, who made the like discovery about the same time. It is Dr Lister's opinion that this darting of threads was known to Aristotle and Pliny (vide *Hist. Anim.* lib. ix. cap. 89; and *Plin.* lib. x. cap. 74), but he believes their sailing was first observed by himself. On these sailing spiders he further observes, that they will often dart, not a single thread alone, but a whole sheaf at once, consisting of many filaments, all of one length, but divided from each other, and distinct; and the longer they become, the more they spread, and appear like the numerous rays of a blazing star. He observed, too, that some species seemed to use their legs as oars, sometimes closing, and again spreading them out, as occasion might require. When the air is still it is highly probable they can direct their course, and perhaps mount or descend at pleasure. In rowing, he observed they always take their flight backwards. These threads mount to an almost incredible height, and may always be observed in a fine clear day in autumn, when there is little or no wind. In a letter to Mr Ray, he further states, that "I one day observing the air full of webs, forthwith mounted to the top of the highest steeple on the minster (at York), and could there discern them exceedingly high above me."

If a spider is placed on the top of a pole surrounded by water, it nevertheless effects its escape by means of a silken line, which is ere long found to extend from the pole to some other object on the outside of the pool. It is evident that the spider possesses the power of permitting the material of which its threads are composed to escape at pleasure; but whether this is accomplished by a projectile force, by electrical agency, or by the mechanical action of the external currents of the atmosphere, is still a subject of dispute. The beautiful regularity with which the radiated parts of the web are usually disposed favours the idea expressed by a French writer, that the animal possesses the power of shooting out its threads and directing them at pleasure towards a determined point; whilst the observations of Messrs Rennie and Blackwall indicate the necessity of a current of air as a moving force. It appears, from the experiments of the latter gentleman, that when spiders are placed upon an insulated twig surrounded by water, and exposed to a current of air, however slight, either naturally or artificially produced, they directly turn the thorax towards the quarter from whence it came, and elevating the abdomen, they emit from their spinners a small portion of glutinous matter, which is instantly carried out in a line, consisting of four finer ones, with a velocity equal or nearly so to that of the air. They next carefully ascertain whether their lines have become firmly attached to any object, by pulling at them with their anterior pair of legs; if the result satisfies them, they glue the nearer end to the twig, and then march across. "Such was invariably the result when spiders were placed where

[1] *Introduction to Entomology*, vol. i. p. 414.
[2] *Voyage à la Recherche de la Perouse; Introduction to Entomology*, vol. i. p. 302.

the air was liable to be sensibly agitated: I resolved therefore to put a bell glass over them, and in this situation they remained 17 days, evidently unable to produce a single line by which they could quit the branch they occupied, without encountering the water at its base; though, on the removal of the glass, they regained their liberty with as much celerity as in the instances already recorded." (*Linn. Trans.* vol. xv.) Mr Blackwall affirms with confidence, that in motionless air, spiders have not the power of darting their threads even through the space of half an inch. Mr Murray, Mr Bowman, Mr Mark Watt, and others, maintain a contrary opinion.

Lastly, Mr Virey thinks it more probable that spiders actually fly (by vibrating their feet) through the air, than that they are acted upon either by electrical influences or the agitation of the air. He does not assert that they have wings.

The bodies of spiders decompose so rapidly after death, that both their forms and colours are speedily altered and effaced. It is therefore with great difficulty that they are preserved as subjects of examination in museums. Hence, perhaps, our comparative ignorance both of their structure and habits.

Sect. I.—Tetrapneumones.

Two spiracles and two pulmonary sacks or pneumobranchia on each side.

This section is characterized by the position of the eyes, which are always placed at the anterior extremity of the thorax, and usually close to each other. The mandibles (*chelicères* of Latreille) and feet are robustly formed. The greater proportion of species have only four spinners. They fabricate silken tubes, in which they dwell, and these are placed sometimes in subterranean tunnels, sometimes under stones, and sometimes beneath the bark or among the leaves of trees.

The first division of the section corresponds to the *Theraphoses* of Walckenaer, and contains the three following genera, viz. Mygale, Atypus, and Erodion. These are distinguished from the others by having four spinners and eight eyes, and by the hooks of their mandibles being bent underneath instead of inwards.

Genus Mygale, Walckenaer.—Palpi inserted at the superior extremity of the maxillæ, in such a manner that they appear to be composed of six articles, of which the first, straight and elongated, with the inner angle of its upper portion projecting, performs the function of a jaw. The languette is small and nearly square. The last joint of the palpi in the male is button-shaped, and bears at its extremity the reproductive organs; and the two anterior legs in that sex are provided with two strong spines or spurs at their inferior extremity.

This genus, as established by Walckenaer, is composed of the bird-catching spiders (*A. avicularia*, Linn.), and the *Araignées mineuses* of Olivier. It contains several species of great size and singular habits. The foreign kinds are as yet imperfectly characterized. The habits of a large species found in Martinique, where it is called *Matoutou*, have been well described by Moreau de Jonnés. It spins no web, but lies concealed in holes and crevices of the volcanic tufa, from which, however, it makes frequent excursions in search of prey, which consists not only of insects, but of humming-birds and other species of the feathered race. It hunts chiefly during the night. It is possessed of great muscular strength, and unwillingly quits an object of which it may have become possessed. When induced to seize upon any hard and polished substance, it leaves traces of a poisonous liquid, which, had the substance been of a yielding nature, it would have injected into the wound. This liquid is lactescent, or of a milky aspect, and very abundant in proportion to the size of the animal. The female carries her eggs in a cocoon of white silk, of a very close texture, which she holds by means of her palpi, beneath the thorax. When attacked, she drops her eggs to defend herself, and secures them again when the combat has ceased. The young, when first produced, are entirely white; and the earliest change which they experience is the appearance of a black spot in the centre of the dorsal surface of the abdomen. From eighteen hundred to two thousand young have been observed to proceed from a single silk bag; but of these it is probable that an immense proportion perish in infancy, by the depredations both of birds and insects.

Several species of this genus inhabit Europe, and their characters and economy are detailed by Olivier, Latreille, the Abbé Sauvage, and other writers. Our restricted limits prevent our describing more than a few, which we shall select as well from the indigenous as exotic.

† Superior extremity of the mandibles unprovided with a series of transverse spines or corneous points. Tarsi furnished with a thick hairy brush, which conceals the crotchets.

Sp. Avicularia.—*Aranea Avicularia*, Linn. The bird-catching spider, Shaw. (Pl. XLVI. fig. 1)—Body nearly two inches long, very hairy, especially in the young. Thorax depressed, large, oval, truncated posteriorly. General colour black; the extremities of the palpi, the feet, and inferior hairs of the mouth, reddish. Hooks of the mandibles strong, conical, and very black. This species is said to dwell in the clefts of trees, and in hollows among rocks and stones. According to Madame Merian, it surprises small birds on their nests, and sucks their blood with avidity. It forms a tube-shaped cell, narrow at its posterior extremity, composed of a fine white semi-transparent tissue, resembling muslin. The cocoon of this species is like a large walnut in size and form. Its native countries are Cayenne and Surinam. Other nearly allied species also occur in those parts of South America, as well as in Africa and the East Indies. Their bite is dangerous, although the accounts given by Piso and other authors is no doubt exaggerated. To this section may be referred the *M. blondi* (Pl. XLVI. fig. 2), *cancerides*, *fasciata*, *atra*, and *brunnea* of Latreille.

†† Superior extremity of the first piece of the mandibles provided with corneous points like the teeth of a rake. The tarsi are not so covered with hair as to conceal the crotchets.

The species of this section inhabit dry and mountainous places, where they form tunnels or subterranean galleries, sometimes two feet in depth. At the entrance they construct a door, moving upon a hinge, and formed of silk and clay, undistinguishable from the surrounding soil. There is what we may not improperly call a mat of silk fastened to the inner surface of the door, on which the animal frequently reposes, probably for the sake of guarding the entrance, and being at hand to secure its passing prey. A fine silk tube, which is the proper dwelling, clothes the interior of the gallery. M. Dufour is of opinion that the females alone excavate the tunnels.

Sp. Cæmentaria.—*Araignée mineuse*, Dorthes. In *Linn. Trans.* ii. (Pl. XLVI. fig. 3.)—The female of this species is about eight lines in length, of a reddish-brown colour, somewhat pale on the edges of the thorax. The mandibles are blackish, and are each furnished near the articulation of the crotchet with five points, of which the innermost is the shortest. The abdomen is mouse-coloured, with darker spots. The first article of all the tarsi is

furnished with small spines, the crotchets of the last have a spire at their base, and a double range of pointed teeth. The spinners are but slightly projecting. The *M. carminans* of M. Latreille (2d edit. of the *Nouv. Dict. d'Hist. Nat.*) is supposed to be the male of this species. He differs in the greater length of his legs; in the crotchets of the tarsi, of which the teeth are more numerous; in the want of the spines, and the greater shortness of the spinners. His two anterior feet are terminated beneath by a strong spine.

This species inhabits Spain, the southern parts of France, and other shores of the Mediterranean. Its habits are presumed to be nocturnal, as it is never seen abroad or at work during the day.[1] It forms its tunnel in strong earth, free from stones, and on a sloping surface to avoid moisture. It resists the opening of its door with its utmost strength, and continues struggling in the entrance till the light has fairly entered, after which it retreats into the earth. The door is beautifully formed, and suspended on a hinge from above, so that it always shuts close of its own accord. It preys upon beetles and other large and strong insects. When its door is cut off or unhinged, it forms another in its place, which, according to Rossi, differs from the first in not being movable. The Italian author does not mention by what means its entrance and exit are then accomplished; but Latreille has suggested that the experiment may have been tried just before the commencemen of winter, and that the second operculum was closed with a view to exclude the rigours of that inclement season.

In the following genera of this division the palpi are inserted upon an inferior dilatation of the external side of the maxillæ, and consist of only five articles. The languette, at first very small, as in the genus Atypus, afterwards becomes elongated and advanced between the jaws. The last joint of the palpi in both sexes is lengthened and antennated towards the extremity. The males are not provided with a strong spur at the extremity of the two anterior legs.

Genus Atypus, Latreille. Oletera, Walckenaer.—Languette very small, and almost covered by the external portion of the base of the maxillæ. Eyes contiguous, and grouped upon a tubercle.

Sp. Sulzeri, Latreille. *Aranea Picea*, Sulzer. (Pl. XLVI. fig. 4.)—General colour blackish. Length of the body eight lines. Thorax nearly square, depressed posteriorly, enlarged and broadly truncated in front. The mandibles are strong, and their claw is furnished near the base with a tooth-like projection. The last article of the palpi in the male is pointed at the extremity.

This is the only species of the genus known in Europe. It was first described by Sulzer as a Swiss species (*Geschichte der Insecten*. Pl. XLVI. fig. 2). It has since been observed by several French entomologists at Sevres, near Paris, and was discovered in this country by Dr Leach, near Exeter. Its habits are curious and interesting. It constructs for its dwelling a silky scabbard, intermingled with moss, eight or ten inches long. Its direction is at first horizontal over the surface of the ground, and then perpendicular beneath the surface. The eggs are deposited at the bottom, enveloped in a white web. The animal itself is slow in its movements. It is most frequently met with in the month of July. It appears to have been described and figured by Roemer as the *subterranean spider*.

An American species, the *Atypus rufipes* of M. Milbert, of which the body is entirely black, and the feet rufous, occurs in the neighbourhood of Philadelphia.

Genus Erodion, Latreille. Missulena, Walckenaer.—This genus differs from the preceding in its straight, elongated languette, which projects between the jaws. Its eyes are spread over the front of the thorax.

Sp. Occatorius, Latreille, Walckenaer. Body black, about an inch in length. Brought from New Holland by M. Lesueur.

The second division of this section exhibits the prolonged languette of the Erodions, and the palpi composed of five articulations; but the claws of the mandibles are folded inwards instead of downwards. The spinners are six in number; and the first pair of legs, instead of the fourth, are the longest. Some of these Arachnides have only six eyes.

Genus Dysdera, Latr. Walck.—Eyes six, disposed in the form of a horse-shoe, opening outwards. Mandibles strong and projecting. Maxillæ straight, and dilated towards the insertion of the palpi.

Sp. Erythrina (Pl. XLVI. fig 5.)—Mandibles and thorax sanguineous; colour of the legs lighter. Abdomen soft and silky, and of a grayish yellow.

Inhabits the south of France and England, beneath stones. It is rare in the latter country, but has been taken near Plymouth, Exeter, and London. A variety of this species has been described by Scopoli under the name of *Aranea hombergii*.

Genus Filastata, Latr.—Eyes eight, placed on a small elevation at the anterior extremity of the thorax. Mandibles small; maxillæ arched on their exterior side.

Of this genus the *F. testacea* of Walckenaer was discovered near Marseilles. The *F. bicolor* is described in the *Faun. Franc. Arach.* vi. 1–3.

Sect. II.—Dipneumones.

A. Sedentariæ.

The genera of this great division are possessed of only a pair of pulmonary sacks, and corresponding stigmata. The palpi, composed of five joints, are inserted on the exterior side of the maxillæ, near their base, generally in a sinus. The languette is advanced between the maxillæ, and is sometimes nearly square, sometimes triangular or semicircular. The spinners are six in number. The last article of the palpi in the males is more or less ovoid, and usually contains the generative organs in an excavation.

The first four tribes of this section may be considered as forming a large group, which we name *Sedentariæ*. They either spin webs for the capture of their prey, or throw out isolated and irregular threads for the same purpose. Their eyes are grouped across the front of the thorax. Of these there are usually eight; four or two in the centre, and two or three on each side. Sometimes there are only six eyes.

The first three of these tribes, viz. *Tubitelæ, Inæquitelæ*, and *Orbitelæ*, are sometimes included under the more general appellation of Rectigrade, from their straightforward mode of progression, particularly as contrasted with that of the fourth tribe or *Laterigradæ*, which, like many of the crustaceous class, can direct their steps in different directions without turning the body. In these tribes the relative length of the legs is variable. In many the first and the last pair are the longest; in others the two

[1] The eyes of spiders are occasionally observed to shine in the dark like those of cats, moths, &c., and they probably enjoy the faculty of seeing both by night and day.

Arachnides.

anterior pairs; while in some the third and fourth pair are the most extended. The eyes, in their general disposition, do not form a crescent, or the segment of a circle.

TRIBE I.—TUBITELÆ.

Spinners cylindrical, close to each other, directed backwards. The feet are robust; the first and last pair are the longest.

GENUS CLOTHO, Walckenaer. UROCTEA, Dufour.—Mandibles very small, capable of little extension, and without teeth. Crotchets small, body short, legs long, the third and fourth pair rather longer than the preceding. The eyes are disposed as in genus Mygale. The maxillæ have on their external side a slight dilatation at the insertion of the palpi, and terminate in a point. The languette is triangular. The superior or lateral spinners are the longest; but the most peculiar character, according to M. Dufour, is the existence, in the position of the intermediate spinners, of a pair of comb-shaped valves, which open or close at the will of the animal.

Sp. 5-maculata.—Body about an inch in length, of a chesnut-brown colour; the abdomen black, with five small round yellowish spots, of which four are disposed transversely in pairs, and the fifth is single and posterior.

This species was found in Egypt by M. Savigny. It occurs in Dalmatia, and near Montpellier; also in Catalonia, and other parts of Spain. Its manners have been described by M. Dufour.

GENUS DRASSUS, Walck.—Mandibles robust, projecting, toothed beneath. Maxillæ obliquely truncated at their extremity. The eyes are nearer the anterior edge of the thorax, and the line formed by the four posterior exceeds in length that formed by those on the anterior line. The fourth and second pair of feet are obviously longer than the others. The legs and first joints of the tarsi are armed with sharp points.

The spiders of this genus live under stones, in the clefts of walls, and among leaves. They form little dwelling-places of white silk. The cocoons of some are orbicular, flattened, and composed of two valves applied one against another.

Sp. Relucens.—Small, cylindrical, with a yellow thorax, covered with a purple silky down. The abdomen is thin, red, and green, with metallic reflections, and two transverse lines of golden yellow, of which the anterior is arched. One variety has also four additional golden spots. The species is generally found running on the ground. It is common in the environs of Paris, and is one of the most beautiful of the tribe.

GENUS SEGESTRIA, Latr.—Eyes six, of which four are anterior on a transverse line, and two posterior, placed on each side behind the two lateral eyes of the preceding line. The languette is elongated and almost square. The first and second pair of feet are the longest, and the third pair the shortest.

The species of this genus spin cylindrical elongated webs in the clefts of old walls, in which they lie concealed, with their anterior pair of legs stretched forwards. Divergent threads of glutinous silk border the external opening to their habitation, and form a net for the capture of their insect prey.

Sp. Senoculata.—Thorax blackish-brown. Abdomen oblong, grayish, with a longitudinal band of blackish spots. Legs pale brown, obscurely banded. Inhabits rocks and old buildings.

GENUS ARANEA, Latr. TEGENERIA, Walck.—The two upper spinners conspicuously longer than the others. The four anterior eyes placed in a curved line, bending backwards. The first and last pair of legs the longest.

This genus inhabit the interior of our dwellings; also the angles of old walls, on plants, hedges, &c. They construct large webs, nearly horizontal, at the higher part of which is a tube or tunnel, where the spider lies concealed.

Sp. Domestica.—Of a livid ash colour. Thorax of the male without spots. On that of the female there is on each side a blackish band. Abdomen blackish, with a longitudinal spotted band on the back.

This is the most frequent inhabitant of our houses, and an object of more than common aversion. It sometimes attains to a large size. According to Homberg, it is subject, especially in the kingdom of Naples, to a disease which renders it more than usually hideous. Its body becomes covered with scales, among which a number of mites engender. Geoffroy was of opinion that a spider was supplied only with a certain portion of spinning material; that if the web was intentionally destroyed, and an individual frequently obliged to reconstruct its web, it became at last incapable of further exertion in that line, and would probably perish for want of the usual means of subsistence.

The spiders of this country are entirely harmless, from their want of power to pierce the skin. But that they are furnished with a poisonous liquid, which they instil into the wound of their victims, cannot be doubted. Olivier, indeed, reports, that a farmer in one of the Isles d'Hières was bitten by a large spider while turning a sheaf of wheat. The wound occasioned at first only a slight inflammation, so trivial that it was for some time neglected, till its increase created alarm. Gangrene and death ensued. They may be taken internally with impunity. " J'ai vue," says Latreille, " le célèbre astronome Lalande avaler de suite quatre gros individus de cette espèce." (*A. domestique.*)

GENUS ARGYRONETA, Latr.—Maxillæ inclined upon the languette, of which the form is triangular. The four central eyes form a quadrangle; the lateral pair of each extremity are grouped together, and placed on a small eminence.

Sp. Aquatica. Aranea Aquatica, Lin. Geoff.—Of a blackish-brown colour, the abdomen deeper, surface silky, the back with four impressed points. Lives in ditches and slow-running waters, beneath the surface of which it spins a beautifully constructed web. " The habitation of *aranea aquatica*, the other spider to which I alluded, is chiefly remarkable for the element in which it is constructed, and the materials that compose it. It is built in the midst of water, and formed in fact of air! Spiders are usually terrestrial; but this is aquatic, or rather amphibious: for though she resides in the midst of water, in which she swims with great celerity, sometimes on her belly, but more frequently on her back, and is an admirable diver, she not unfrequently hunts on shore, and having caught her prey, plunges with it to the bottom of the water. Here it is she forms her singular and unique abode. She would evidently have but a very uncomfortable time were she constantly wet; but this she is sagacious enough to avoid, and, by availing herself of some well-known philosophical principles, she constructs for herself an apartment, in which, like the mermaids and sea-nymphs of fable, she resides in comfort and security. The following is the process:—First she spins loose threads in various directions, attached to the leaves of aquatic plants, which may be called the frame-work of her chamber; and over them she spreads a transparent varnish resembling liquid glass, which issues from the

middle of her spinners, and which is so elastic that it is capable of great expansion and contraction; and if a hole be made in it, it immediately closes again. Next she spreads over her belly a pellicle of the same material, and ascends to the surface. The precise mode in which she transfers a bubble of air beneath this pellicle is not accurately known; but from an observation made by the ingenious author of the little work from which this account is abstracted, he concludes that she draws the air into her body by the anus, which she presents to the surface of the pool, and then pumps it out from an opening at the base of the belly, between the pellicle and that part of the body, the hairs of which keep it extended. Clothed with this aerial mantle, which to the spectator seems formed of resplendent quicksilver, she plunges to the bottom, and, with as much dexterity as a chemist transfers gas with a gasholder, introduces her bubble of air beneath the roof prepared for its reception. This manœuvre she repeats ten or twelve times, until at length, in about a quarter of an hour, she has transported as much air as suffices to expand her apartment to its intended extent, and now finds herself in possession of a little aerial edifice—I had almost said an enchanted palace—affording her a commodious and dry retreat in the very midst of the water. Here she reposes unmoved by the storms that agitate the surface of the pool, and devours her prey at ease and in safety. Both sexes form these lodgings. At a particular season of the year the male quits his apartment, approaches that of the female, enters it, and enlarging it by the bubble of air that he carries with him, it becomes a common abode for the happy pair.[1] The spider which forms these singular habitations is one of the largest European species, and in some countries not uncommon in stagnant pools."[2]

Tribe II.—Inæquitelæ.

External spinners conical, convergent, slightly projecting, disposed *en rosette*. Legs slender, first and last pair usually the longest. The maxillæ are inclined on the tongue, and are either narrow or present no sensible enlargement at their superior extremity. The abdomen is more voluminous, softer, and more highly coloured than in the preceding tribe. Their webs constitute an irregular net-work of various forms, the threads of which cross each other in different directions. They bind their prey with cords, which, though silken, secure them very effectually. The species are short-lived, and tend their eggs very carefully till the exclusion of the young.

Genus Scytodes, Latr.—Eyes six, disposed in pairs. M. Dufour states that the crotchets of the tarsi are inserted in a supplementary article.

Sp. Thoracica. (Pl. XLVI. fig. 6.)—Pale reddish-white, spotted with black. Thorax large, somewhat orbicular. Abdomen not globose.

This species inhabits houses. It has been found near Dover, but is otherwise scarcely known as a British species.

Genus Theridion, Walck.—Eyes eight in number, of which four in the centre form a square, the two anterior being placed upon a small eminence, and a pair are placed on each side upon a common elevation. The thorax is almost triangular, or shaped like a heart reversed.

Sp. Malmignatto. *Aranea 13-guttata*, Fab.—Lateral eyes, separated from each other. Body black, with thirteen small round spots of a blood-red colour on the abdomen. This species inhabits Corsica, the inhabitants of which island hold it in great dread, from the belief that its bite is dangerous, if not mortal.

Another species, the *Theridion benignum* of Walckenaer, may from its name be presumed to possess another character. It lives in autumn among the clusters of grapes, where it watches for its prey, and thus deters many insects from injuring the fruit. The prejudice against this genus probably arises from several of them being of a dark colour, with red spots resembling drops of blood upon their bodies.

Genus Episinus, Walck.—Eyes eight, near each other, and placed upon a common elevation. The thorax narrow and almost cylindrical.

Sp. Truncatus.—Thorax acute in front, rather longer than broad, obscure brown above, reddish brown beneath. Abdomen pyramidal, truncated behind, its anterior portion brown, third pair of legs whitish, the others brown.

Genus Pholcus, Walck.—Eyes eight, tuberculated, divided into three groups, of which there is one on each side composed of three eyes disposed in a triangle, and a third in the centre, somewhat advanced, composed of two eyes on a transverse line.

Sp. Phalangioides, Walck. *Araignée domestique à longues pattes*, Geoff.—Body long, narrow, pubescent, of a livid or pale yellow colour. The abdomen is almost cylindrical, very soft, and spotted above with black. The legs are very long and slender, with whitish rings at the extremities of the thighs and tibiæ.

This species is common in houses in the western parts of England. Its body vibrates like that of some tipulæ. The female carries her eggs in an agglutinated mass between her mandibles.

Tribe III.—Orbitelæ.

In this tribe the exterior spinners and the legs resemble those of the preceding, but the maxillæ differ, being straight, and sensibly broader at their extremity. The first and second pair of legs are the longest. The eyes are eight in number, of which four are placed quadrangularly in the centre, and a pair on each side. These spiders differ from the *Inæquitelæ* in the form of their webs, which are composed of a regular net-work, formed of concentric circles, crossed by straight lines or radii, proceeding from the centre, where the animal lies, to the circumference. Some conceal themselves in cavities, or in chambers built by themselves, near the margins of their webs, which are sometimes horizontal, sometimes perpendicular. Their eyes are numerous, agglutinated, and inclosed in a large cocoon.

Genus Linyphia, Latr.—Four central eyes, of which the posterior pair are larger, and separated by a larger space; the others are in pairs, one on each side, and placed obliquely. The maxillæ are enlarged at their superior extremity.

This genus constructs among brooms and other bushes a slender, open, horizontal net, from which various threads proceed irregularly upwards to different points.

[1] *Mémoire pour servir à commencer l'Histoire des Araignées Aquatiques.*
[2] *Introduction to Entomology*, by Kirby and Spence, vol. i. p. 469.

Sp. Triangularis.—Pale red, inclining to yellow. Thorax with a dark dorsal line, bifid in front. Abdomen oval, inclining to globose, with spots and angulated bands of brown and white. Inhabits the European hedges, and constructs its webs on brooms and pine-trees.

Genus Uloborus, Latr.—Four posterior eyes placed at equal distances on a straight line, and the two lateral eyes of the first line nearer the anterior margin of the thorax than the intermediate pair, so as to form an arch bent backwards. The maxillæ commence in this genus to enlarge a little above their base, and terminate in the form of a spatula. The tarsi of the last three pair of legs are terminated by a single claw. The first article of the two posterior pair have a range of small hairs.

These spiders repose in the centre of their webs, with their four anterior feet stretched forwards; the third pair are extended laterally, and the posterior pair backwards.

Sp. Walckenarius, Latr.—Of a reddish-yellow colour, covered by a silky down, forming on the upper part of the abdomen two series of small bundles. Length about five lines. The legs are marked with paler rings. Occurs near Bordeaux, and other southern departments of France.

Genus Tetragnatha, Latr.—Eyes placed four and four on two nearly parallel lines, and separated by almost equal intervals. Maxillæ long, narrow, enlarged only at their superior extremity. Mandibles also very long, especially in the males. Their web is vertical.

Sp. Extensa.—Abdomen oblong, golden green, with the sides and two lower lines yellowish. Sits with its legs extended on a vertical web. Inhabits moist places.

Genus Epeira, Walck.—A pair of eyes on each side, almost contiguous; the other four forming a central quadrangle. The maxillæ dilated from their base.

With the exception of that of *E. curcubitina*, which is horizontal, the webs of this genus are either vertical or inclined. Some repose in the centre of their webs, with their bodies reversed, or heads downwards; others construct a sheltering habitation, sometimes formed of leaves spun together, sometimes like a silken tube, or of a more open form like a bird's nest, in the vicinity of their nets. Some foreign species construct such powerful webs as to arrest the flight of small birds, and even to incommode the traveller while journeying through the forests. Many of the species are remarkable for the beauty of their colours, their singular forms, and still more singular habits. Between 60 and 70 species are described by M. Walckenaer in his *Tableau des Aranéides;* and M. Leon Dufour has greatly contributed to illustrate the history of this extensive genus in the *Annales des Sciences Physiques* of Brussels, and the *Annales des Sciences Naturelles* of Paris. We regret that the limits of our present undertaking do not admit of our entering into further details.

Sp. Diadema. (Pl. XLVI. fig. 7.)—Reddish; abdomen globose-oval, with an elevated angle on each side near the base; dorsal band darker, broad, triangular, dentated, with a triple cross of yellowish-white spots, and four impressed dots disposed in a quadrangle. Legs and palpi spotted with black.

This is one of the largest of the British species. It frequents the borders of woods, rocks, and gardens; also moors and other desert places. It varies considerably both in size and colour. We are indebted to Treviranus for an account of its anatomical structure. The heart presents a character not observed in that of any other species. From its inferior and anterior part proceed two muscles, which, at first united in one, diverge as they approach the posterior portion of the abdomen. The heart itself exhibits several branches, the two anterior of which are sent to the branchia; and the function of these last-named organs, according to Treviranus, is to absorb humidity from the atmosphere, and convey it to the circulating system. The true respiratory organs are discoverable in a species of stigmata placed in the thorax and abdomen. These stigmata are not pierced, like those of insects; but numerous vessels are seen distributed over their surface.

The sceptre or diadem spider, as this species is frequently called, pairs about the end of summer, and deposits its eggs in autumn. The eggs are of a fine yellow, inclosed in a cocoon of a close texture, but covered with a looser substance of a yellowish hue. This spider forms no nest, but shelters itself beneath a leaf or some other natural covering. Its web is large and vertical. The young are hatched in spring, and are at first yellow, with a blackish spot on the upper part of the abdomen.

M. Vautier has described a singular species of this genus, remarkable for the posterior enlargement of its abdomen, which is terminated by a couple of arched and elongated spines. (*Annales des Sciences Naturelles*, tome i. p. 261.) It is named *Epeira curvicauda.* (Pl. XLVI. fig 8.)

Tribe IV.—Laterigradæ.

The species which constitute this tribe are, like those of the preceding, of sedentary habits; but they differ in their mode of progression, being able to walk sideways and backwards, as well as straight forward like the others. Hence the designation of the tribe. Their four anterior feet are always longer than the others. In some the first pair are longer than the second; in others they are nearly equal. The mandibles are usually small, with their crotchets transversely folded, as in the preceding tribes. The eyes are always eight in number, frequently unequal, and forming by their union a crescent, or the segment of a circle. The maxillæ in the generality of this species are inclined upon the lip. The body is generally flattish, crab-shaped, with the abdomen large, rounded, and triangular.

The genera included in this division can scarcely be said to spin webs,—they merely throw out a few isolated threads. They are usually found on plants, tranquil and stationary; sometimes concealed between two leaves, of which they fasten the edges together. They watch their eggs with great care till the young are hatched.

Genus Micrommata. Sparassus, Walck.—Maxillæ straight, parallel, rounded on their edges. Eyes disposed four and four, on two transverse lines, of which the posterior is the longer, and arched backwards. The second and first pair of feet are the longest. The languette is semicircular.

Sp. Smaragdina.—Colour bright green, sides bordered with yellow. Abdomen greenish-yellow, with a darker green line upon the back.

This species places its cocoon in the centre of three or four leaves fastened together and lined with silk.

Genus Senelops, Dufour.—Maxillæ straight, or slightly inclined, without lateral sinus, pointed, and obliquely truncated on the internal side. Languette semicircular. Six eyes in front, on a transverse line; two others behind, one on each side. The legs are long; the first pair are the shortest.

Sp. Omalosoma.—Four lines in length, very flat, of a reddish-gray colour, with cinereous spots, and the feet ringed with black. The abdomen appears to present

posteriorly the vestige of rings or segments, forming a sort of dentation along the sides.

This rare species was discovered by M. Dufour in the kingdom of Valentia. It inhabits rocks, and runs with singular rapidity. It occurs both in Egypt and Syria.

Genus Philodromus, Walck.—Maxillæ inclined upon the languette, which is higher than broad. The eyes, nearly equal in size, are disposed in the form of a cross or semicircle. The mandibles are lengthened and cylindrical.

Sp. Tigrina.—Thorax very broad, flattened, of a reddish fawn-colour, brown laterally and posteriorly, white in front. The pentagonal abdomen variously coloured by means of minute red, brown, and white hairs, by which it is covered. It is bordered with brown along the sides, and is marked on the dorsal region with from four to six impressed points. The belly is whitish. The legs are long, slender, reddish, with brown spots.

This species is common on trees. When touched it immediately either runs off with great rapidity, or suddenly drops to the ground. Its cocoon, of a beautiful white colour, incloses about one hundred unagglutinated eggs. It places them in the clefts of trees, and guards them with great care.

Genus Thomisus, Walck.—Mandibles shorter than in the preceding genus, wedge-shaped. Four posterior feet, shorter than the others. The sexes frequently differ in their size and colours.

Sp. Citreus.—Colour citron-yellow. The abdomen large, broader behind; the back with two red spots. Inhabits flowers. The female is common in Britain; the male more rare, of a smaller size, brown, banded with yellowish-green.

B. Erraticæ.

The four preceding tribes are characterized by their usually sedentary habits. The remainder of the Araneides are of a more wandering disposition. This is in proper accordance with their other capabilities; for, as they cannot spin webs for the capture of their prey, they are under the necessity of moving about from place to place to extend the sphere of those exertions, the successful issue of which depends on agility as well as cunning. "Such," says Evelyn, "I did frequently observe at Rome, which, espying a fly at three or four yards distance, upon the balcony where I stood, would not make directly to her, but crawl under the rail, till, being arrived to the antipodes, it would steal up, seldom missing its aim; but if it chanced to want anything of being perfectly opposite, would, at first peep, immediately slide down again,—till, taking better notice, it would come the next time exactly upon the fly's back; but if this happened not to be within a competent leap, then would this insect move so softly, as the very shadow of the gnomon seemed not to be more imperceptible, unless the fly moved; and then would the spider move also in the same proportion, keeping that just time with her motion, as if the same soul had animated both these little bodies; and whether it were forwards, backwards, or to either side, without at all turning her body, like a well-managed horse; but if the capricious fly took wing and pitched upon another place behind our huntress, then would the spider whirl its body so nimbly about, as nothing could be imagined more swift; by which means she always kept the head towards her prey, though, to appearance, as immovable as if it had been a nail driven into the wood, till by that indiscernible progress (being arrived within the sphere of her reach) she made a fatal leap swift as lightning upon the fly, catching him in the pole, where she never quitted hold till her belly was full, and then carried the remainder home."[1]

Though the species above alluded to, and others constituting the ensuing tribes, spin no webs, they are yet provided with a sufficiency of the necessary material to enable them to construct cocoons for their eggs, and also to throw out an occasional thread to break their fall when leaping on a vertical surface.

The eyes of the erratic spiders are always eight in number, and are grouped rather along than across the thorax, forming a curvilinear triangle, or a truncated or quadrilateral oval. One or two pair of eyes are generally much larger than the others. The thorax is large, and the legs robust.

Tribe V.—Citigradæ.

In this tribe the legs are generally fitted for running. The maxillæ are always straight, and rounded at their extremities. The eyes are grouped in a curvilinear triangle, or in an oval or oblong figure, of which the anterior side is much narrower than the thorax taken in its greatest breadth. The thorax itself is ovoid, narrower in front, and somewhat ridged or keel-shaped in its longitudinal centre.

The females for the most part keep close to their cocoons, which they carry about them, either suspended at their extremities, or applied between the chest and the base of the abdomen. They watch over their young for some time after they are hatched.

Genus Oxyopus, Latr. Sphasus, Walck.—Eyes ranged two and two on four transverse lines, of which the two at the extremes are the shortest; they describe a kind of oval figure, truncated at each end. The languette is elongated, narrow at the base, dilated and rounded at the extremity. The first pair of legs is the longest; the fourth and second are nearly equal; the third is the shortest.

Sp. Variegatus.—Body hairy and gray, variegated with red and white. Legs pale reddish, spotted with brown; the tibial *spines* elongate. Inhabits France.

Sp. Lineatus. (Pl. XLVI. fig. 9.)—Abdomen elongated, yellowish, with lengthened black spots on the sides, and a black longitudinal band beneath. This species forms its web on low growing plants, but nestles among the leaves of trees about the period of laying.

Genus Ctenus, Walck.—Eyes placed on three transverse lines (2, 4, 2) forming a curvilinear triangle, reversed, and truncated anteriorly. The languette is square and almost isometric. The fourth pair of feet are the longest; the first pair are next in length; the third are the shortest.

This genus, according to Latreille, was established for the reception of a species found in Cayenne. Others, possessed of the same generic characters, have been found both in that colony and in Brazil, but their descriptions have not yet been made public.

Genus Dolomedes, Latr.—Eyes disposed on three transverse lines (4, 2, 2,) representing a quadrilateral figure, somewhat broader than long. The two posterior are

[1] Evelyn's *Travels in Italy.*

placed upon an eminence. The second pair of legs are equal to the first, if not somewhat longer; and the fourth pair are the longest of all. The languette is square, and, like that of the preceding genus, is as broad as high.

Of this genus, some have the two exterior eyes of the anterior line larger than the pair comprised between them; and the form of the abdomen is oblong oval, with a terminal point. The females construct a silken nest, funnel-shaped, or in the form of a bell, which they place in a thicket, or among leaves near the summit of a tree. In this they deposit their cocoons of eggs, of which they are exceedingly careful. When they leave their retreats, either to hunt for prey, or from any cause of alarm nearer home, they never fail to carry their bundle of eggs along with them. Clerk (*Aranei suecicæ*) mentions his having observed species of this genus spring with great activity upon flying insects.

Other species of Dolomedes have the four anterior eyes of equal size, and the abdomen oval, and rounded at the extremity. These inhabit the margins of water, run over the surface with agility, and even proceed a little beneath the surface without being wetted. The females form coarse irregular nets, suspended between the branches of plants, and place their cocoons upon them.

Sp. Mirabilis. Aranea saccata, Linn.—Colour pale reddish, covered with grayish down. Thorax heart-shaped, anteriorly abruptly sloping; the anterior angles and dorsal line whitish. Abdomen conical, suboval; darker on the back. Inhabits the woods of Europe. The female carries about her eggs inclosed in a dirty orange-coloured or whitish bag.

Genus Lycosa, Latr.—Eyes disposed in a quadrilateral figure, longer than broad, the posterior pair not placed on an eminence. The first pair of feet are sensibly longer than the second, but shorter than the fourth, which are the longest of all. The maxillæ are truncated obliquely at their external extremity. The languette is square, but rather longer than broad.

The species of this genus run swiftly on the ground. They live in holes, either previously formed by the accidents of nature, or hollowed out by themselves, and fortified along their interior walls by silken threads. Some dwell in the cavities of walls, where they form silken tunnels, covered externally by minute particles of earth and sand. In these retreats they undergo the periodical renewal of their skins; and also pass the winter, after having previously closed up the outer orifice of their dwellings. The females likewise deposit their eggs in these elongated cells. Their cocoons are usually fixed to the extremity of the abdomen, and when the mothers go abroad, they have thus no difficulty in carrying their eggs along with them. As soon as the young are hatched, they collect on the back of the female parent, and remain there till they gain sufficient strength to shift for themselves. The species are exceedingly voracious, and defend the possession of their domiciles with the greatest courage.

Sp. Tarentula. Aranea tarentula, Linn.—(Pl. XLVI. fig. 10.)—Colour ashy brown above; thorax with a radiated line, and margins griseous; abdomen marked anteriorly with trigonal spots, posteriorly with arcuate transverse streaks of black, bordered with white; beneath saffron-coloured, with a transverse black band; thighs and tibiæ beneath rufous white, with two black spots.

This species, an inhabitant of the south of Europe, is the celebrated tarentula, of which so many extraordinary accounts have been given by travellers. It is scarcely necessary to observe that these are fabulous. Its bite was said to produce symptoms equally severe with those of the most malignant fever, and of such a nature as to admit of being cured only by means of music. Some authors have even given a list of the tunes which are most efficacious in restoring the *tarentolati* (for so the patients were called) to health. The true tarentula occurs in the south of Italy, especially near the town of Tarentum, from which it has no doubt derived its name. It is the largest of the European species.

A species of this genus exists in the south of France, which bears a close resemblance to the Italian species, and appears to have been confounded with it by Olivier. It is the *Lycosa Melanogaster* of Latreille, and the *Tarentula Narbonensis* of Walckenaer, and differs from the species above described chiefly in being somewhat less, and in having the abdomen black beneath, and the edges only of a red colour.

Genus Myrmecia, Latr.—Eyes placed on three transverse lines; four in front, then two somewhat nearer the centre than the outer eyes of the first line, and two others behind the preceding pair. The mandibles are strong. The maxillæ are rounded and hairy at the extremity. The tongue is almost square, somewhat longer than broad. The feet are long, almost filiform, the fourth and first pair being the longest. The thorax appears as if divided into three portions, of which the anterior is the largest, and of a square form; and the others are hunched or knot-shaped. The abdomen is much shorter than the thorax, and is covered from its origin as far as the middle by a solid epidermis.

Sp. Rufa.—Length about six lines. Fulvous, shining, nearly smooth, with the extremities of the palpi, the thighs, the first article of the posterior feet, and the end of the abdomen, blackish. Found near Rio Janeiro.

Tribe VI.—Saltigradæ.

In this group the eyes are placed in a square figure, of which the anterior line extends along the breadth of the thorax. The thorax is demi-ovoid, or nearly square; flat, or but slightly bulged above; as broad before as elsewhere, and sloping suddenly down the sides. The legs are adapted both to running and leaping, and the thighs of the anterior pair are generally remarkably large and strong.

Several of the species construct among leaves and stones small oval sacks of silk, open at both ends, in which they seek refuge during bad weather, and while changing their skins. When any danger threatens these retreats they appear on the outside, and after a moment's reconnoitring run off with great agility. The females form small tents, which afterwards serve as cradles for their young, and where the mother and her progeny dwell for some time together. The males, in their battles with each other, exhibit many singular manœuvres.

The genus *Tessarops* of M. Rafinesque, and that of *Palpimanus* established by M. Dufour, both belong to this tribe. That first mentioned is said to have only four eyes. The latter is very rare, and was discovered in Valentia We are not yet acquainted with the characters of either

Genus Eresus, Walck.—Four eyes approached in a small trapezium, near the centre of the anterior portion of the thorax; and four others on its sides, forming a larger square. The languette is pointed and triangular. The tarsi are terminated by three crotchets.

Sp. Moniligerus.—Black; abdomen above cinnabar-coloured, with four or six black dots, arranged in two longitudinal lines; joints of the legs whitish; hinder sides of the thorax, the thighs, and the first joint of the four hinder legs, pale cinnabar. This is the *Aranea quadrigut-*

tata of Rossi's *Fauna Etrusca*. It inhabits France, Germany, and England.

GENUS SALTICUS, Latr. ATTUS, Walck.—Four eyes on a transverse line on the anterior portion of the thorax, the two intermediate larger than the others; the remaining eyes are placed two and two on each side of the thorax; they thus form a kind of parabola or part of a square, open posteriorly. The languette is very obtuse, and truncated at the summit. The tarsi have only two crotchets at their extremity. The mandibles of many of the males are very large. The shape of the thorax and the length and proportions of the legs vary according to the species.

Sp. Scenicus. Aranea scenica, Linn.—Black, margin of the thorax covered with white down; abdomen short ovate, covered above by a reddish white pubescence, with three transverse arcuate lines, and the termination white; the first band is basal and entire, the others acutely bent anteriorly, and interrupted in the middle.

This species is called in Britain the hunting spider. It occurs on walls and palings, and is a common species, of considerable beauty. It loves exposure to light and heat, and is frequently seen near windows in sunny weather. Its movements are lively and amusing. When it sees a fly or a gnat it moves towards it with a slow and gentle motion, and then springs upon it with a single rapid bound. It leaps upon its prey as securely down a perpendicular wall as on a horizontal surface, by means of a thread which, previous to each of its bounds, it has the precaution to attach to the plane of its position. The palpi of the female are whitish; her legs reddish-gray, with darker spots. The mandibles of the male are very large.

FAMILY II.—PEDIPALPI.

Palpi very large, extended in the form of arms, and terminated either by pincers or a claw. Mandibles with two fingers, of which one is movable. Abdomen composed of distinct segments, without any terminal spinners. Sexual organs at the base of the abdomen. Thorax consisting of a single piece, and presenting near its anterior angles three or two eyes, approached or in groups, and two other eyes close together in the centre of its anterior or posterior margin. Four or eight pulmonary sacks.

TRIBE I.—TARENTULÆ.

Our present division corresponds to the genus tarentula of Fabricius. The abdomen is attached to the thorax by a pedicle, or by a portion of the transverse diameter, without comb-shaped plates at its inferior base, or sting at its extremity. The stigmata are four in number, placed near the base of the abdomen, and covered by a plaque. The mandibles are terminated merely by a claw or movable crotchet. The languette is elongated, narrow, dart-shaped, concealed. Maxillæ two, formed by the first joint of the palpi. Eyes eight, of which three are disposed in the form of a triangle near each anterior corner, and two are placed upon a tubercle near the centre of the anterior margin.

Naturalists have as yet acquired but a slight knowledge of this tribe of Arachnides. They inhabit chiefly the warmest countries of Asia and America.

GENUS PHRYNUS, Olivier.—Palpi terminating in a claw. Body flat, thorax broad, crescent-shaped. Abdomen without a tail. The two anterior tarsi long, slender, antenniform.

This genus was named Tarentula by Fabricius, but we prefer retaining the name previously bestowed by Olivier, not only on account of its possessing a prior claim, but because the term Tarentula, as generally understood, applies to a spider of the genus *Lycosa*, the *Aranea tarentula* of Linnæus.

Sp. Lunatus. (Pl. XLVI. fig. 11.)—The arms or foot-palpi of this species are nearly three times the length of the body. They are unfurnished with spines, except at the extremity of the fourth article. This is the *phalangium lunatum* of Pallas. *Spicil. Zool.* fasc. 9. tab. fig. 5, 6.

Sp. Reniformis. Phalangium reniforme, Linn. Herbst. *Tarentula reniformis*, Fabr. (Pl. XLVI. fig. 12.)—Arms very spiny on their interior margins; the third and fourth articulations elongated. The fifth articulation is furnished with four spines. According to Maugé, this species is much dreaded by the negroes of the Antilles.

GENUS THELYPHONUS, Latr.—Palpi shorter and thicker than those of the preceding genus, terminated by pincers or double fingers. Body long, thorax oval, abdomen furnished with a slender articulated prolongation or tail. The anterior tarsi are short, with few articulations.

This genus appears to have been confounded by Gronovius with *Scorpio*, by Linnæus with *Phalangium*, and by Fabricius with *Tarentula*. It forms the passage in the natural progress of generic forms to the scorpion tribe.

Sp. Caudatus, Latr. *Phalangium caudatum*, Linn.—(Pl. XLVI. fig. 13.)—Some confusion seems to exist in regard to the exact or characteristic locality of this species. It is now said to occur in Java. South America furnishes another species, called by the inhabitants of Martinique *vinaigrier*, on account of its extremely acid odour.

TRIBE II.—SCORPIONIDES.

Abdomen sessile, or united to the thorax by its entire breadth, and furnished at its lower base with two movable comb-shaped plates, and terminated by a knotted base, armed with a sting at its extremity. Stigmata eight in number, four on each side along the belly. Mandibles terminated by two fingers, of which the exterior is movable.

The thorax of scorpions assumes the form of a lengthened square. There is a triangular appendage at the base of each of the four anterior feet, which in combination produce the appearance of a lip of four divisions; but of these, according to the views of Latreille, the lateral pair ought to be regarded as maxillæ, and the two others as forming the languette. The abdomen is composed of twelve articulations, including those of the tail, which are six in number. The first division of the abdomen is composed of two parts, the anterior of which bears the sexual organs, the posterior the comb-shaped appendages. These last-named parts are composed of a principal portion, narrow, lengthened, jointed, movable at its base, and furnished along its inferior side with a range of small, narrow, elongated, parallel plates, hollowed interiorly, united to the principal piece before mentioned, and somewhat resembling the teeth of a comb; their number seems to vary according to the species, and probably even with the age of the individual. The uses of these organs in the economy of the animal have not yet been determined. The four following segments of the abdomen have each a pair of pulmonary sacks and stigmata. Immediately behind the sixth segment the abdomen becomes suddenly narrow, and the six following knotty rings compose the tail, terminated by an arched slender point, beneath the extremity of which are two small holes, from which, at

the will of the animal, there flows a poisonous fluid, contained in an interior reservoir. The tarsi resemble each other, and are composed of three articulations, the last of which is armed with a pair of crotchets. The four posterior legs have a common base, and the first article of the haunches is as it were soldered; the posterior pair are in part joined by their back part to the abdomen.

Two nervous cords, which derive their origin from the brain or superior ganglion, unite at intervals and form seven other ganglia, of which the last belongs to the tail. In all other Arachnides, according to Latreille, the number of these ganglia never exceeds three.

Eight stigmata mark the position of an equal number of whitish purses, containing a great number of small delicate plates, among which it is believed the air permeates. A muscular vessel prevails along the back, and communicates by means of two other vessels with each of these purses. The intestinal canal is straight and slender. The liver is composed of four pair of glandular bunches, which discharge their fluid into the intestines at four points. The females are viviparous.

Scorpions occur in the warmer regions of Europe, Asia, Africa, and America. Several of the larger exotic species are poisonous, but the bite of the European kinds is rarely attended by fatal consequences, except to small animals. Maupertuis tried various experiments upon dogs and poultry with the scorpions of Languedoc. Only one dog died. The others, as well as the poultry, though repeatedly stung by *exasperated* scorpions, suffered no injury. Redi's experiments on pigeons were followed by a different result. They generally died in convulsions in about five hours after the infliction of the wound. Some, however, appeared to suffer no inconvenience from the bite of these animals. This difference may be attributed to the particular condition, or rather the quantity of the poison contained in the vessels at the time of the trial. The scorpions of Tuscany are so harmless that they are handled by the peasants without any fear.

Scorpions generally inhabit sombre and shady places, under stones, among old ruins, deserted dwelling-houses, and even, though more rarely, such as are occupied by man. They prey upon various kinds of insects, which they sting with their envenomed tails. They are very fond of the eggs of spiders and of insects. In running, they usually carry their tails curved forwards over their backs; and they possess the power of moving them in all directions, either as offensive or defensive weapons. We have already mentioned that they produce their young alive. Redi states the number of these to amount to between 26 and 40, but some species are more prolific. Maupertuis found from 27 to 65 in the bodies of those which he examined. They were suspended or connected by a lengthened thread, and each was inclosed in a very delicate membrane. The European kinds appear to produce in August, and are afterwards observed to change their skins. Some naturalists are of opinion that they couple twice a year. The female carries her young for several days upon her back, and watches over and defends them for about a month.

In the preceding generalities we have given the principal characters of the old genus scorpio. That genus has been recently divided into two, in conformity with the number of the eyes.

Genus Scorpio, Latr.—Eyes six.

Sp. Europæus.—Colour brown, varying in shade. Feet and terminal joint of the tail of a paler yellowish brown. Claws angular and heart-shaped. Pectens, or comb-shaped appendages, each with nine teeth.

The characters given by Linnæus to his S. Europæus do not accord with our observations on those found in France and Italy. "Cauda sub aculeo mucronata est." An American species is furnished with a projecting point *beneath the sting*, and the existence of that feature in the Transatlantic species seems to have induced De Geer to mistake the latter for the one described by Linnæus as inhabiting the southern countries of Europe.

Genus Buthus, Leach.—Eyes eight.

Sp. Occitanus. (Pl. XLVI. fig. 14.)—Colour yellowish or reddish. Tail rather longer than the body, with elevated and delicately granulated lines. Each pecten furnished with 28 teeth or upwards. About two inches in length.

This is the species experimented on by Maupertuis. He inclosed about 100 in one place, and after the lapse of a few days he found only 14 survivors, which had killed and eaten their companions. It occurs in France, Portugal, and Spain; likewise in Barbary.

Sp. Afer. (Pl. XLVI. fig. 15.)—Nearly half a foot long, and of a blackish-brown colour, with large heart-shaped claws, chagrined on their surface, and slightly haired. A notch in the anterior angle of the thorax. Number of teeth in each comb, thirteen. Occurs both in Africa and India.

Sp. Americanus.—Body slender, elongated, yellowish, with brown spots. Combs with twenty-eight teeth. Arms long and thin; claws filiform. Tail three times the length of the body. Sting with a point beneath. Inhabits America.

The *Scorpio dentatus* of Herbst is allied to the preceding. It inhabits Sierra Leone.

Order II.—Trachearíæ.

The Tracheal Arachnides are distinguished by their respiratory organs, which consist of radiated or branched tracheæ, receiving air only by two stigmatic openings. They possess no (ascertained) circulating system, and their eyes vary from two to four. Müller assigns six eyes to the *Hydrachna umbrata*, but Latreille is of opinion that some optical or other deception may have interfered with the usual accuracy of the great Danish naturalist. The respiration of the Pycnogonides is unknown, no stigmata having been observed in that family.

The Arachnides of this order are the smallest of their class. Some species are almost microscopical. They are naturally divided into two great divisions. Those which belong to the first are more nearly allied to the preceding order, the pulmonary Arachnides, in the form and structure of their masticating organs; such as pertain to the second have the parts of the mouth more simply constructed of certain parts, which, in union with the languette, constitute a kind of trunk or sucker. But many of the species are so minute, even in their general dimensions, that the examination of these organs, and the consequent classification of the species in accordance with a *cibarian* system, are attended with considerable difficulty, and, in the opinion of Latreille, ought not to be had recourse to, except in default of other more obvious characteristics.

The long-legged spider (commonly so called), which is a species of *Phalangium*, frequently met with in hay fields and other places during the summer season, is a familiar example of this order. So also are mites and other acarideous species.

Family I.—Pseudo-Scorpiones.

Thorax articulated, the anterior segment the larger. Abdomen distinct and annulated. Palpi large, in the form of feet or claws. Both sexes with eight feet, having two equal hooks at the end of the tarsi, the two anterior

sometimes excepted. Two mandibles (*antenne-pinces* or *chelicères* of Latreille) terminated by a couple of fingers; and two maxillæ formed by the first article of the palpi. This family consists of two genera, the habits of which are terrestrial; their bodies oval or oblong.

GENUS GALEODES, Oliv. SOLPUGA, Lichtenstein.

Mandibles very large, with vertical, strongly toothed fingers, of which one is superior, fixed, frequently furnished at its base with a slender pointed appendage; the other movable. Palpi large, advanced, in the form of feet or of antennæ, terminated by a short button-shaped article, vesicular and hookless. Anterior pair of feet resembling the palpi, but smaller; they are also hookless. Each of the other feet has the terminal joint of the tarsus furnished with a pair of hooks. The posterior pair of feet have five remarkable scaly excrescences placed upon foot-stalks, and ranged along the inferior surface of their first two articulations. The eyes, two in number, are very close to each other, and are situated on an eminence of the anterior portion of the first segment of the thorax, which presents the appearance of a large head bearing the anterior pair of feet, in addition to the masticating organs.

According to M. Dufour the terminal article of the palpi incloses a particular disc-shaped organ, of a whitish colour and pearly lustre, not visible externally unless the animal is irritated. The lip (*labre*) has the form of a small beak, much compressed, recurved, pointed, and hairy. The languette is small, keel-shaped, and terminates in two divergent threads, each placed on a small articulation. Latreille perceived a pretty large stigmatic opening on each side of the body, between the first and second feet, and another cleft at the base of the abdomen. The abdomen is oval and composed of nine rings. We lately received two species of this genus from Persia.

Sp. Araneoides, Olivier. (Pl. XLVII. fig. 1.)—*Solpuga Arachnoides*, Herbst.—Colour pale yellowish-brown. Inhabits Africa and the western countries of Asia.

GENUS CHELIFER, Geoff. OBISIUM, Illiger.—Palpi elongated, furnished with didactile pincers at their extremity. Eyes placed on the sides of the thorax. Legs nearly equal in size, each terminated by a pair of crotchets. Body flat. Thorax almost square.

These animals run swiftly, both backwards and forwards. They carry their eggs about with them after the manner of spiders. The elder Hermann is of opinion that they spin webs. Such of the species as have the thorax divided or impressed by a transverse line form the genus Chelifer of Dr Leach. Their eyes are two in number. Others have the thorax undivided, and of these the eyes amount to four. They form the genus Obisium of the last-named author.

Sp. Fasciatus.—Hands oval. Segments of the abdomen bordered with white. Lives beneath the bark of willow and other trees. Sometimes occurs near London. Leach, in *Linn. Trans.* xi.

Sp. Cancroides. (Pl. XLVII. fig. 2.)—This species measures about a line and a half in length. The body and legs are of a reddish brown. The palpi are about twice the length of the body. It is a European species, inhabiting old books, herbariums, &c. and preys upon the bodies of several destructive insects. It ought therefore to be cherished in the live state by collectors.

FAMILY II.—PYCNOGONIDES.

Trunk composed of four segments, occupying almost the entire length of the body, terminated at each extremity by a tubular article, of which the anterior portion, sometimes simple, sometimes accompanied by mandibles (*antenne-pinces*) and palpi, or by one or other of these organs, constitutes the mouth. Both sexes have eight feet proper for running; but the females are moreover provided with two false feet, placed near the anterior pair, and serving to carry the eggs.

The species of which this family is composed inhabit the sea. They usually keep themselves concealed among sea-weed along the shores, and feed upon small marine animals. Their movements are slow. Their bodies are generally linear, the legs very long, composed of from eight to nine articles, and terminated by two unequal crotchets, of which the smaller is cleft. The first articulation of the body, or that which represents the head and mouth, forms an advanced, nearly cylindrical tube, pierced at its extremity by a triangular opening. It also bears the mandibles and palpi. The former are linear or cylindrical, composed of two pieces, of which the last is pincer-shaped, with the inferior or fixed claw shorter than the other. The palpi are filiform, with a crotchet at the end, and composed of from five to nine articles. Each of the succeeding segments of the body, with the exception of the last, serves as a point of attachment to a pair of legs; and the segment which articulates with the mouth is provided on its dorsal portion with a tubercle bearing the eyes, and on its ventral portion (in the females) with a small additional pair of feet on which the eggs are distributed. The terminal segment is small, cylindrical, and pierced at its extremity. The stigmatic openings in the bodies of this family have not yet been discovered.[1]

M. Savigny is of opinion that this family forms the natural transition from the class Arachnides to the crustaceous tribes, and great uncertainty still prevails in the minds of naturalists regarding their true position in the system. We place them in the position which they now occupy in our present arrangement, in accordance with the views of M. Latreille. M. Milne Edwards, who has studied these animals in their native places, informed that celebrated entomologist, that in the interior of the Pycnogonides he observed cæca or lateral expansions of the intestinal canal.

GENUS PYCNOGONUM, Brunnich.—In this genus the mandibles and palpi are wanting, and the length of the feet scarcely exceeds that of the body, which is proportionally short and thick. The species are parasitical on cetaceous animals.

Sp. Balænarum. (Pl. XLVII. fig. 3.)—*Phalangium Balænarum*, Linn.—Inhabits the European Ocean. This species is frequently taken by the trawl-fishers in Plymouth Sound. It has been found by M. d'Orbigny on the coasts of France.

GENUS PHOXICHILUS, Latr.—In this genus the palpi are wanting, as in the preceding; but we observe a pair of mandibles, and a greater elongation of the legs.

To this genus belong *Pycnogonum spinipes* of the *Fauna Groenlandica*, *Phalangium hirsutum* of Montagu (*Linn. Trans.* ix.), *Nymphon hirtum* of Fabricius, &c.

GENUS NYMPHON, Fab.—Resembles the preceding genus

[1] Recent observations induce the belief that these creatures breathe through their skins,—a peculiar character, which, when satisfactorily established, may lead to their being erected into a separate order, intermediate in some respects between the Arachnides and the apterous insects of the parasitical order. (See *Règne Animal*, tome iv. p. 277, *note*.)

in the narrow and oblong form of its body, the length of its legs, and the presence of mandibles; but in addition to these organs there are likewise a pair of palpi.

Sp. Gracile, Leach. (*Zool. Misc.* i. 45.)—Colour cineıeous; thighs cylindrical. Inhabits most parts of the British seas. We are doubtful whether this species should be considered as synonymous with the *Nymphon grossipes* (*Phalangium grossipes*, Linn.) figured on Pl. XLVII. fig. 4. The term *grossipes* is certainly very inapplicable to either kind.

Genus Ammothea, Leach.—Mandibles much shorter than the rostrum, with equal joints, the fingers arcuate, and meeting at their tips. Palpi nine-jointed, the third joint very long. Legs slender; coxæ with the middle joint longest; tibiæ with the first joint rather the shortest; tarsi with the first joint small; claws double, unequal. Egg-bearing organs nine-jointed, inserted under the first legs, behind the rostrum.

Sp. Carolinensis. (Pl. XLVII. fig 5.)—Body entirely brown, testaceous; back with three trigonate tubercles. (*Zool. Miscell.* i. 34.) From South Carolina.

Family III.—Holetra.

The groups composing this family are characterized by the union of the thorax and abdomen in a single mass, beneath a common epidermis. The thorax is almost divided into two by a contraction; and the abdomen, in some species, presents the appearance of rings, formed by the folds of the epidermis. The anterior extremity of the body frequently projects in the form of a beak or muzzle. The generality are provided with eight feet; some have only six.

Tribe I.—Phalangita, Latr.

Mandibles very conspicuous, terminated by didactylous pincers. Palpi filiform, and composed of five articles, of which the last is terminated by a small nail. Two distinct eyes. Two maxillæ formed by a prolongation of the radical article of the palpi; and besides these there are sometimes four other jaws, which, however, result merely from a dilatation of the haunches of the first two pair of legs. Body oval or rounded, and covered, at least on the thorax, by a skin of a somewhat solid texture. The legs, which are always eight in number, are long, and distinctly divided, like those of insects. Many are provided near the origin of the two posterior legs with two stigmata, one on either side, concealed by the haunches. The species of this tribe are for the most part of active habits. The generative organs are placed internally beneath the mouth.

Genus Phalangium, Linn. Fab.—Mandibles projecting, much shorter than the head. Eyes placed upon a common tubercle. The feet are long and slender, and when separated from the body they for some time afterwards exhibit signs of irritability. The females are provided with a membranous oviduct, filiform, annulated, and flexible. The tracheæ are tubular.

The species of this genus are of predacious habits. They prey upon small insects, which they seize with their mandibles, pierce with their crotchets, and suck to death. They are of pugnacious tempers. Though analogous to spiders in their external forms, they cannot spin. They are short-lived, as those hatched in the spring are all supposed to die in the autumn.

Sp. Cornutum, Linn. (the male). *Opilio, ejusd.* (the female).—Body oval, reddish or ash-coloured above, white beneath. Palpi long. Two rows of small spines on the tubercle which bears the eyes. Thighs with prickles. Mandibles horny in the males. A blackish band with a festooned border on the back of the female.

Of certain species of this genus Mr Kirby has formed his genus *Gonoleptes.* (See *Linn. Trans.* vol. xii. Plate XXII. fig. 16.)

Genus Siro, Latr.—Mandibles projecting, almost as long as the body. Eyes distant, each placed upon an isolated tubercle.

Sp. Rubens. (Pl. XLVII. fig. 6.)—Colour pale red; legs paler. Dwells in moss at the roots of trees.

Genus Macrocheles, Latr.—Mandibles long and projecting. Eyes sessile, or none. Two anterior feet, very long, and antenniform. The upper part of the body forms a plaque or scale, without any distinct rings.

According to Latreille, the *Acarus marginatus* and *tes tudinarius* of Hermann (*fils*) belong to this genus.

Genus Trogulus, Latr.—Anterior extremity of the body advanced in the form of a hood or *chaperon*, and receiving in an inferior cavity the mandibles and other parts of the mouth. The body is very flat, and cover ed by a strong skin.

Sp. Nepæformis.—Colour obscure ash-colour. Central portion of the dorsal part of the abdomen, and the sides, obsoletely subcarinated. External apex of the first joint of the tarsi produced. Inhabits France and Germany, lurking beneath stones.

Tribe II.—Acarides.

Sometimes furnished with mandibles composed of a single pincer, didactylous or with a simple claw, and concealed in a sternal lip; sometimes furnished with a sucker formed of plates or laminæ joined together. A few have only a simple cavity for the mouth, without additional appendages.

The species of this tribe (corresponding to the genus *Acarus* of Linnæus) are almost microscopical, and are universally distributed. Some are erratic, and occur in a great variety of situations, among stones, on trees, among flour, cheese, and various other substances, whether animal or vegetable; others are parasitical on the skins of living creatures, which they sometimes greatly weaken by their excessive multiplication. The disease called itch, if not occasioned by, is at least in some way connected with, the presence of minute species of this family. Dr Galet has demonstrated that that disease may be communicated by the transmission of mites from one (infected) individual to another. Small mites have even been found in the brain and in the eyes of the human race.

Many of the species, when first produced, have only six feet. They are oviparous, and deposit a great number of eggs.

Genus Trombidium, Fab.—Mandibles *en griffe*, or terminated by a movable claw. Palpi projecting, pointed, with a movable appendage or finger at the extremity. Two eyes, each placed at the end of a small fixed pedicle. Body divided into two parts, of which the first or anterior is very small, and bears, besides the eyes and mouth, the first two pair of legs.

Sp. Holosericeum.—Of a blood-red colour. Abdomen almost square, narrower behind, and notched. Back furnished with papillæ, hairy at the base, and globular at their extremities. Common in gardens during spring.

Sp. Tinctorum. (Pl. XLVII. fig. 7.)—This species is three or four times larger than the preceding. It occurs in the East Indies, and produces a fine dye.

Genus Erythræus, Latr.—Mandibles and palpi as in Trombidium, but the body is undivided, and the eyes are not mounted on a pedicle.

Sp. Phalangioides.—Legs very long, the last joint broad, compressed. Body obscure red, with a dorsal band of orange yellow. Inhabits most European countries, running on the ground with great rapidity.

Genus Gamasus, Latr.—Mandibles didactylous; palpi projecting, distinct, filiform.

Some species of this genus have the upper surface of the body clothed, in whole or in part, with a scaly skin, while others are entirely soft.

Sp. Coleoptratorum.—Anterior pair of legs somewhat longer than the others. Coriaceous parts of the back fuscous.

Inhabits the excrements of horses and cattle, and is frequently found adhering in great numbers to the bodies of coleopterous insects of the genus Scarabæus, Hister, &c.

To this genus belongs the *Acarus marginatus* of Hermann, which is sometimes found in the brain (*corpus callosum*) of the human race.

Genus Cheyletus, Latr.—Mandibles didactylous. Palpi thick, arm-shaped, falcated at the extremities.

Sp. Eruditus. Acarus eruditus, Schrank.—Colour brownish. Inhabits books and museums.

Genus Oribata.—Mandibles didactylous. Palpi short and concealed. Body covered by a coriaceous or scaly skin, in the form of a shield or buckler. Legs long, or of medium length.

The body in this genus is prolonged anteriorly in the form of a muzzle. There is sometimes an indication of a thorax. The ends of the tarsi are terminated by a single crotchet in some, by two or three in others, without any vesicular ball or cushion. The species are found beneath stones, among moss, and on trees. Their movements are slow.

Sp. Geniculata.—Of a brownish chesnut colour, shining, hairy. Legs pale brown, thighs sub-clavate. Common in Sweden, Germany, and England.

Genus Uropoda, Latr.—Mandibles pincer-shaped; palpi not conspicuous. Body covered by a scaly skin, and terminated by a slender filament, by means of which the species adhere to the bodies of coleopterous insects.

Sp. Vegetans. (Pl. XLVII. fig. 8.)—Brown, smooth, and shining. Inhabits France and England, attaching itself to the legs and other parts of insects by its pedunculated anus.

Genus Acarus, Fab. Latr.—Furnished like the preceding genera with didactylous mandibles, and very short or concealed palpi; but the body is soft, and unfurnished with a scaly crust. The tarsi are provided at their extremity with a vesicular tuft. Many species live on the substances used as aliments by the human race.

Sp. Siro. The cheese-mite. (Pl. XLVII. fig. 9.)—Whitish, with two brown spots. Body ovate, the middle coarctate, with long hairs. Legs of equal length. Inhabits houses, feeding on flour and long-kept cheese.

Sp. Scabiei. (Pl. XLVII. fig. 10.)—A microscopical species, which inhabits the skin of man in a diseased state. It appears, from the observations of Bonnani and others, that this insect usually accompanies the disease called the *itch*.

Genus Bdella, Latr.—Palpi elongated, bent, terminated by hairs or bristles. Four eyes, posterior feet the longest. Sucker prolonged in the form of a conical or awl-shaped beak. Found in moss, beneath stones, and under the bark of trees.

Sp. Rubra. La Bdelle rouge of Latreille. (Pl. XLVII. fig. 11.)—Rostrum longer than the thorax. Colour coccineous, legs paler than the body. Dwells beneath stones. This is the *pince rouge* of Geoffroy, and the *Acarus longicornis* of Linnæus. It is a minute insect, measuring scarcely half a line in length.

Genus Smaridia, Latr.—Distinguished from the preceding genus by the palpi, which are scarcely longer than the sucker; straight, and without bristles at the extremity. Eyes two. Anterior pair of legs longer than the others.

Sp. Sambuci. Acarus Sambuci, Schrank.—Colour red, the body slightly haired. Movements slow. Dwells beneath the bark of trees, more especially that of the elder, observed by Latreille in the south of France. This genus is represented in Pl. XLVII. fig. 12., by a figure of *Smaridia passerina.*

Genus Ixodes.—Palpi inclosed in the sucker, along with which they form a short projecting beak, truncated, with a slight expansion at the end.

The animals of this genus occur among bushes and underwood, from which they detach themselves to fasten on dogs, sheep, cattle, and other quadrupeds, to which they adhere with remarkable tenacity. Their eggs, of which they lay a prodigious quantity, are, according to M. Chabrier, obtruded by the mouth.

Sp. Reduvius. Acarus reduvius, Linn. (Pl. XLVII. fig. 13.)—The colour and appearance of this species vary according to its state of repletion. The legs are black.

Genus Argas.—Palpi conical, composed of four articles, not inclosed in the sucker.

Sp. Reflexus. Acarus marginatus, Fab. (Pl. XLVII. fig. 14.)—Pale yellowish, or flesh-coloured, with deeper anastomosing lines. Inhabits houses in France, sucking the blood of doves.

A species of this genus found in Persia (the *malleh de mianeh*) is considered to be extremely poisonous. It appears, however, from the observations of M. Szovits, a naturalist recently employed by the Russian government to explore the Caucasus, that the bite of these bugs of Miana, as they are sometimes called (*Argas Persicus* of Fischer), is in reality by no means dangerous.

The three following genera correspond to the genus *Hydrachna* of Müller. Their habits are aquatic, and their forms oval, or nearly globular, and of a soft consistence. The number of their eyes varies from two to four, and even to six, according to Müller. They were usually confounded with the mites till the time of the last-named observer, who inferred that as they lived habitually in a different element, they ought to form a separate division. They resemble small spiders, and probably on that account received the name of Hydrachna, which signifies water-spider. Fabricius, who only employed in the formation of his groups characters drawn from the structure of the mouth, has united Hydrachna with Trombidium. The observations of Latreille have led not only to the distinct separation of these two genera, but to the subdivision of the genus Hydrachna into at least three distinct groups of species, all of which may be readily distinguished from the various kinds of mites (Acari) by their ciliated or natatorial legs.

The minute beings now under consideration occur

abundantly in stagnant or slowly moving waters. The spring season is the most favourable for the observance of their habits. They *run* through the water with great rapidity, with a continual movement of their legs. Their dispositions are carnivorous, and their food consists of animalcular species, of minute insects, small flies, and aquatic larvæ. Müller kept many Hydrachnæ in vessels of water full of *animalcula infusoria*, millions of which were eaten in a few days, soon after which the Hydrachnæ were found in a state of great languor, and transparent from exhaustion. They speedily revived when a few drops of water containing animalcules were mingled with that through which they swam.

The males are usually much less than the females, and the sexes frequently differ in colour. Only four or five species were known before the time of Müller, to whose persevering labours we owe the best elucidation which has yet been given of their history.[1]

Latreille is of opinion that the structure of the masticating organs authorizes the establishment of the three generic groups which follow.

Genus Eylais, Latr.—Mandibles terminated by a movable crotchet.

Sp. Extendens. Atax extendens, Fab. (Pl. XLVII. fig. 15.)—Body rounded, smooth, shining, immaculate, red. Hinder legs straight. Inhabits stagnant waters.

Genus Hydrachna, Latr.—Mouth composed of plates forming a projecting sucker. Palpi provided at their extremity with a moveable appendage.

Sp. Geographica. (Pl. XLVII. fig. 16.)—Black, marked with coccineous spots. Inhabits gently flowing waters. A beautiful species, not uncommon in several parts of Britain.

Sp. Cruenta. (Pl. XLVII. fig. 17.)—Distended, red; legs of nearly equal length. This is the *Trombidium globator* of Fabricius, and the *mite aquatique ronde* of De Geer.

Genus Limnochares, Latr.—Resembles Hydrachna in its sucker-shaped mouth, but the palpi are simple.

Sp. Holosericea.—Body ovate, red, rugose, soft; eyes black. This is the *Acarus aquaticus* of Linnæus, and the *mite satinée aquatique* of De Geer. Inhabits the waters of Europe, and occurs frequently in ponds during the summer months. It varies in colour from a bright red to a grayish red. According to Fabricius, it deposits its eggs on water scorpions (*Nepæ*).

The remaining genera are distinguished from all other Arachnides by having only six legs. Their habits are parasitical.

Genus Caris, Latr.—Sucker and palpi apparent. Body rounded, very flat, and covered by a scaly skin.

Sp. Vespertilionis.—Body fuscous. Found on bats.

Genus Leptus.—Sucker and palpi apparent. Body soft and ovoid.

Sp. Autumnalis. Acarus Autumnalis, Shaw. (Pl. XLVII. fig. 18.)—Colour red, very minute. Common during the summer months on grasses and other plants, from which it detaches itself, and fixing in the skin of the human species, occasions an insupportable itching. "Acarus Autumnalis," says Dr Shaw, "popularly known by the name of the harvest bug, is also one of the most minute of the genus, and is of a bright red colour, with the abdomen bent on its hind part, with numerous white bristles. This troublesome insect will make itself sufficiently known to most people, during the months of July, August, and September. It is easily distinguishable on the skin by its bright red colour, and adheres so tenaciously when it has once fixed itself, as to be scarcely separated without violence; its motion when disengaged is pretty quick, though by no means equal to that of some other acari. On the part where it fixes it causes a tumour, generally about the size of a pea, sometimes much larger, accompanied by a severe itching. These insects abound on vegetables, and are generally contracted by walking in gardens, amongst long grass, or in corn fields." (*General Zoology*, vol. vi. p. 464.)

According to Mr White of Selbourne, this minute creature greatly abounds in the chalky districts of Hampshire. He was assured that the warreners are much infested by them, and are sometimes thrown into fever by their bites. Another species is common on *Phalangium opilio.*

Genus Aclysia, Audouin.—Form like that of a bagpipe. A syphon, without distinct palpi, placed beneath the anterior extremity, which is narrow, curved, and obtuse. The legs are very small.

The species of this genus are parasitical on the bodies of water-beetles of the genus *Dytiscus.* The only one of which we have any knowledge (*A. dytisci*) is described by M. Victor Audouin, in the 1st vol. of the *Mém. de la Soc. d'Hist. Nat. de Paris.* We found it on *Dytiscus marginalis*, in the vicinity of Edinburgh. A second species has been recently discovered in Russia by Count Manheiren.

Genus Astoma, Latr.—Neither sucker nor palpi visible. The mouth consists merely of a small opening, situated in the breast. The body is soft, and oval; the legs very short.

Sp. Parasitica. (Pl. XLVII. fig. 19.)—Body coccineous, slightly contracted in the centre. This is the *mite parasite* of De Geer. It inhabits the bodies of flies and other insects.

Genus Ocypete, Leach.—This genus, arranged by Dr Leach in the same stirps as *Trombidium*, is placed by Latreille at the end of his Hexapod Arachnides. It differs from those with which it is conjoined by the possession of mandibles.

Sp. Rubra, Leach, *Linn. Trans.* xi.—Colour red, back furnished with a few long hairs. The legs are covered with many hairs of a rufous cinerescent colour. The eyes are blackish brown. This curious little animal, which is not larger than a grain of sand, is parasitical, and frequently occurs on the larger tipulæ, adhering to their legs. Dr Leach obtained no less than 16 specimens from one insect.

[1] See O. F. Müller's *Hydrachnæ*, 1 vol. 4to, 1781.

The following more special works may be consulted regarding the Arachnides, in addition to the general system in which they are treated of in their order of occurrence:—A Natural History of Spiders and other curious Insects. By Eleazar Albin. Lond. 1736. Aranei Suecici, descriptionibus et figuris æn. illustrati, &c. By Carolus Clerk. Holmiæ, 1757. Aranei, or the Natural History of Spiders, including the principal parts of the well-known work on the English Spiders, by Eleazar Albin; and also the whole of the celebrated publication on Swedish Spiders, by Charles Clerk, revised and enlarged, &c. (J. W.)

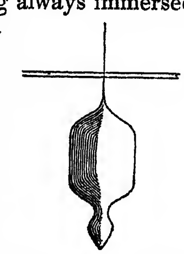
ARACHNOIDES, in *Anatomy*, an appellation given to several membranes,—as the tunic of the crystalline humour of the eye, the external lamina of the pia mater, and one of the coverings of the spinal marrow.

ARACK. See Arrack.

History. ARÆOMETER (composed of αραιος, *levis, tenuis*, and μετρον, *mensura*), a measure of the comparative density and rarity of bodies. The name does not occur in ancient authors; hydroscopium and baryllium being the ancient names of the instrument. This instrument was known in the civilized part of the Roman empire about the year 400, as appears from the fifteenth epistle of Synesius, addressed to Hypatia, daughter of Theon; and to Hypatia some modern writers have erroneously ascribed its invention. The instrument is also described in some verses annexed to Priscian; and the principles on which its operation is founded are to be seen in the treatise of Archimedes on floating bodies (*De Humido Insidentibus*). The term, as used by writers on natural philosophy, is chiefly applied to instruments which are made to float, so as to indicate the specific gravity of the liquids in which they are placed: the *pêse liqueur* and hydrometer, in common use for measuring the specific gravity of vinous spirits, are instruments of this kind.

Theory. A floating body displaces a portion of the liquid, the weight of which is equal to its own weight: the liquid acting upwards with a force equal to this weight, and the weight of the body acting downwards with the same force, equilibrium takes place. If the body be afterwards placed in a liquid of less density, the part of the body immersed will be greater than when the body was in the more dense liquid, because it requires a greater volume of this less dense liquid to equal the weight of the floating body. The absolute weights of two bodies being the same, their specific gravities are in the inverse ratio of their volumes $\frac{G}{g} = \frac{v}{V}$, when G is put for the specific gravity of the first body, g for that of the second; V for the volume of the first, and v for the volume of the second. On this principle the common hydrometer is constructed; the instrument described by Synesius is also of this kind. In order that a small difference in the volume immersed may be sensible, the part which is intersected by the surface of the fluid is in the form of a very slender cylinder, the great bulk of the instrument being always immersed in the liquid. At the inferior part is a small ball, containing mercury or small lead shot, which serves as ballast, bringing the centre of gravity low, so that the instrument may float erect, and without much lateral oscillation. The common hydrometers are made of glass, and sometimes of brass, or tin or pewter, and some have been made of amber as objects of curiosity. When made of glass, a scale, inscribed upon paper, is inserted in the cylindrical stalk: the division of the scale at which the surface of any liquid intersects the stalk, denotes the specific gravity of that liquid.

Aræometer with scale.

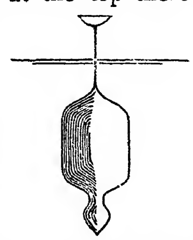


Mode of forming the scale. The divisions of the scale should be formed by immersing the instrument in liquids of known specific gravity, and marking a number corresponding to that specific gravity opposite to each division. The specific gravities of water and alcohol mixed in various proportions have been accurately ascertained by Mr

Gilpin. (See his Tables, and Dr Blagden's paper in the *Philosophical Transactions.*) On immersing the instrument in a mixture of known proportions of these two liquids, the point at which the surface intersects the stalk is to be marked with the number expressing the specific gravity of the mixture taken from the table. Some hydrometers, such as that constructed by the French chemist Beaumé, and which is much used in France under the name of *Aréomètre de Beaumé*, have the scale divided into equal parts, so that the divisions do not correspond as they ought to do with the numbers which express specific gravities.

Fahrenheit's.

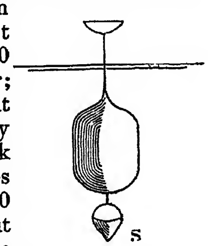
In the aræometer of Fahrenheit, the uncertainty arising from the erroneous division of the scale is obviated, no division being required. The form of the instrument is the same as that just described, only at the top there is a small cup, into which weights are put, so as to bring the surface of the denser liquid to a fixed mark on the stalk: when the instrument is placed in a liquid of less density, some of the weights are taken out till the mark again comes to the surface. Suppose the weight of the instrument and of the weights in the cup together equal to 1000, when sunk to the mark in



distilled water at a certain temperature; the instrument is now taken out of the water and immersed in a liquid, where 10 must be taken out of the cup in order to bring the mark to the surface; the immersion in water indicates that a volume of water weighs 1000; the immersion in the second liquid shows that an equal volume of this liquid weighs 990; when the volumes of bodies are equal, the specific gravities are directly as the absolute weights $\frac{G}{g} = \frac{W}{w}$, consequently the specific gravity of the second liquid is 990, that of water being 1000. To save computation, it is convenient that the whole weight of the apparatus, when in distilled water at a certain temperature, should be represented by 1000; for this purpose the instrument-maker divides the weight of the apparatus into 1000 parts, and forms small weights consisting of one, two, three, &c. of these 1000th parts, the relation of which to the ounce or pound does not require to be known; the weights thus formed are to be used with the instrument.

Nicholson's.

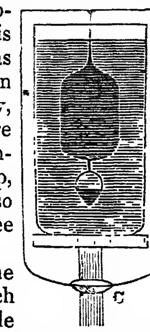
The aræometer of Nicholson is like that of Fahrenheit, with the addition of an immersed cup, whereby it is rendered proper for ascertaining the specific gravity of solids. Suppose that it requires 400 grains in the exterior cup to sink the instrument to the mark in distilled water, at 60 degrees of Fahrenheit's thermometer; 1*st*, The body under examination is put into the exterior cup, and weights (say 300 grains) are taken out till the mark again stands at the surface; this gives the absolute weight of the body 300 grains. 2*dly*, The body is then put into the immersed cup S, taking care



S

to brush off any air-bubbles with a hair pencil, and in order to bring the mark to the surface, a weight (say 100 grains) must be put into the exterior cup, that is, the weight of a volume of water equal to the body is 100 grains. The first part of the process gave the absolute weight of the body 300 grains; and the volumes being equal, the specific gravities are as the absolute weights; consequently the specific gravity of the body is 300, that of water being 100. This aræometer may be used to find the specific gravity of liquids: the process, in that case, is the same as that described above in speaking of the aræometer of Fahrenheit. The aræometer of Nicholson is useful to the mineralogist for ascertaining the specific gravity of minerals, the specific gravity being a convenient character for distinguishing one kind of mineral from another. It is sometimes made of tinned iron, but where more accuracy is required, copper is the material employed. When put together, it does not exceed a foot in length, and therefore is suited to form a part of the travelling mineralogist's apparatus.

Some aræometers have been constructed with the exterior cup C placed underneath, and supported by a stirrup, whose upper part is fixed to the stalk of the aræometer, as represented on the margin. This is done in order to place the centre of gravity low, that the aræometer may thereby float more steadily. The aræometer floats in a cylindrical vessel fitted to the size of the stirrup, and this vessel is supported on a stand so formed as not to interfere with the free motion of the stirrup.



C

Deparcieux's.

The aræometer of Deparcieux is like the common hydrometer, only the ball is much more voluminous. This renders it capable of indicating the small difference which exists in the specific gravity of the water of different springs, for which purpose Deparcieux proposed it. The dilatation of the large glass bulb by heat has a considerable effect on the operation of this instrument, and this dilatation being different in different instruments, renders the results inaccurate. The different aræometers above mentioned have the advantages of being easily made and easily carried about; but where the specific gravity of a body is required with the greatest accuracy, recourse must be had to the hydrostatic balance, which ought to be constructed with the utmost care by the most skilful artist.

The following algebraic expressions may serve to elucidate some of the properties of the aræometers hitherto spoken of:

g is the specific gravity of water, which is 1000 ounces when the ounce and foot are taken as unities, 1000 ounces avoirdupois being the weight of a cubic foot of water.

z is the diameter of the wire-stalk of the aræometer.

π is 3·1415, &c. the number expressing the periphery of a circle whose diameter is 1.

$\frac{1}{4}\pi z^2$ is the surface of a transverse section of the wire-stalk.

v is the volume of the bulb or body of the aræometer.

w is the whole weight of the aræometer.

x is the length of the stalk that is plunged in the water.

$\frac{1}{4}x\pi z^2$ is the volume of the immersed portion of the stalk.

When the aræometer floats in equilibrio, it displaces a volume of water equal to its own weight; therefore, $w = g\,(v + \frac{1}{4}\,x\pi v^2)$, and, $g = \frac{w}{v + \frac{1}{4}x\pi z^2}$, $x = \frac{4(w - gv)}{2g\pi z^2}$.

$w - gv$ is the difference between the quantity of water displaced by the whole aræometer, and the quantity displaced by the bulb alone; $w - gv$, therefore, is the volume of water displaced by the immersed portion of the stalk. As the diameter of the stalk z is very small, the cylinder of water $w - gv$, which has z for its diameter, is likewise very small, and does not exceed a few grains in weight; therefore a small variation in w (the weight of the aræometer), or in g (the density of the liquid), occasions a great variation in x (the length of the immersed part of the stalk). The value of x changes rapidly, when z (the diameter of the stalk) is changed,

Aræometer.

Sensibility to the specific gravity of liquid.

because the value of x is divided by z^2, which is the square of a very small quantity.

When the aræometer is immersed in a liquid of another specific gravity g^1, then the equation is $x^1 = \frac{2(w-g^1 v)}{g^1 \pi z^2}$; subtract the value of x^1 from that of x, and there results $x - x^1 = \frac{2w(g-g^1)}{gg^1 \pi z^2}$. This is the diminution in the length of the immersed part of the stalk, which takes place when the aræometer is transferred to a liquid of a greater density. By this formula it is seen, that the sensibility of the aræometer, that is, the length of the portion of the stalk which emerges upon transferring the aræometer to a denser liquid, is augmented, in the first place by increasing w (the weight of water displaced by the aræometer), that is, by increasing the volume of the body of the aræometer; secondly, by diminishing z (the diameter of the stalk), which is in the denominator of the value of $x - x^1$; consequently, the faculty of the aræometer to show the different densities of liquids is in general expressed by the fraction $\frac{w}{z^2}$.

With regard to the vertical mobility of the aræometer, when put in motion by placing a small weight s in its exterior cup, substitute $w+s$ for w; then, $x^1 = \frac{4(w+s-gv)}{2g\pi z^2}$. Take the difference between this and $x = \frac{4(w-gv)}{2g\pi z^2}$: this difference is $x^1 - x = \frac{4s}{g\pi z^2}$; which shows that the length of the portion of the stalk that a small weight causes to immerge is proportional to $\frac{s}{z^2}$, or in the direct ratio of the small weight, and in the inverse ratio of the square of the diameter of the stalk.

When the small weight, the density of the liquid, and the length of that part of the stalk which is submerged on adding the small weight, are known, then this equation will give the diameter of the stalk in known quantities $z = 2\sqrt{\frac{s}{g\pi(x^1-x)}}$.

When the weight of the whole aræometer is known in ounces, &c., and the specific gravity of one of two liquids (water, for instance) is known, the difference of specific gravity between that liquid and another liquid may be had in known quantities.

g is the specific gravity of water.

g^1 is the specific gravity of the second liquid, which is here supposed more dense.

w is the weight of the volume of water displaced by the aræometer.

s is a small additional weight placed on the exterior cup to keep the aræometer, when placed in the denser liquid, at the same point of immersion as when it floated in water.

$w+s$ is the whole weight of the apparatus when floating in the denser liquid.

The equation $g^1 = \frac{w+s}{v+\frac{1}{4}x\pi z^2}$ is obtained by substituting g^1 for g, and $w+s$ for w, in the equation $g = \frac{w}{v+\frac{1}{4}x\pi z^2}$, which was given above. Divide by $g = \frac{w}{v+\frac{1}{4}x\pi z^2}$, and there results $\frac{g^1}{g} = \frac{w+s}{w}$, which gives the proportion of the density of the second liquid to the density of water. By subtraction there results $\frac{g^1-g}{g} = \frac{s}{w}$ and $g^1 - g = \frac{sg}{w}$; that is, the difference between the density of the second liquid and the density of water is found by multiplying the small weight by 1000 ounces, and dividing this product by the number of ounces, &c. which denote the weight of the aræometer uncharged.

Aræostyle || Arafat.

Bead aræometer.

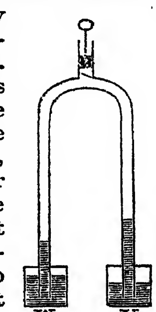
Small bodies, whose specific gravities are known, serve to indicate the specific gravity of a liquid in which they just remain suspended. In this way beads of glass three or four tenths of an inch in diameter are employed, each of which remains suspended in spirit of a certain specific gravity. The density of each of these beads, or rather bubbles, is regulated by the proportion between the quantity of glass and the cavity which the glass incloses. A piece of bees-wax, whose specific gravity, by the addition of lead, is such that the body is just suspended in brine of a known density, is used as an aræometer in some salt works. The fresh egg of a common fowl is just sustained by brine of a certain specific gravity, and is employed as an aræometer.

Homberg's.

The aræometer of Homberg consists of a phial with a slender neck and glass stopper, so made that it may be filled with the same volume of different liquids. It is employed in finding the specific gravity of liquids in the following way: 1*st*, The phial is filled with distilled water, and then weighed in a balance; 2*dly*, the phial is emptied, and again filled with the liquid whose specific gravity is sought, and weighed in a balance: the proportion of the weight of the contents of the phial in the second process to the weight of its contents in the first, is the specific gravity required. The inconveniences which have prevented this method from being generally used are, the difficulty of completely cleaning the phial from the liquid which it previously contained; the difficulty of filling the phial exactly with the same volume of each liquid; and the variation of the volume of the phial from changes of temperature.

Pump aræometer.

The pressure of the atmosphere supports columns of different fluids, whose height is inversely as the densities of the fluids. An aræometer has been constructed on this principle. It is a curved tube, one leg of which has its extremity immersed in water, and the other in the spirit whose density is to be tried. On rarefying the air in the tube, by means of a pump fixed at the upper part of the tube, the water ascends in one leg, and the spirit in the other; the height of the column of each liquid being measured by a scale of equal parts applied to each branch of the tube. This instrument has never come into use, probably on account of the difficulty of ascertaining with precision the points at which the surfaces of the columns are terminated.



(W.A.C.)

ARÆOSTYLE (ἀραίος and στῦλος), in *Architecture*, a term used by Vitruvius to signify the greatest interval which can be made between columns.

ARÆOSYSTYLE (compounded of the Greek words ἀραιός, σύν, στῦλος), in *Architecture*, an arrangement of columns in pairs, with an interval, usually equal to half a diameter, between the coupled columns, and an interval of three diameters and a half between the pairs.

ARÆOTICS (ἀραιωτικά), in *Medicine*, remedies which rarefy the humours, and render them easy to be carried off by the pores of the skin.

ARAFAH, the ninth day of the last month of the Arabic year, named *Dhoulhegiat*, on which the pilgrims of Mecca perform their devotions on Mount Arafat.

ARAFAT, a mountain near Mecca in Arabia, held in high

Aragon. veneration by the Mahometans. A visit to it constitutes a necessary part of the great pilgrimage. (See MECCA.) The mountain consists of a granite rock about 150 feet high, which is ascended by staircases, partly cut in the rock and partly composed of solid masonry. On this hill Adam is said to have met his wife Eve after a long absence; and it is thence called Arafat or *Gratitude*. On the summit is a chapel which the Mahometans believe to have been built by Adam. The interior was destroyed in 1807.

ARAGO, D. F. J. *See Sixth Preliminary Diss.* § 500.

ARAGON, or ARRAGON, a province, or, as it is usually denominated by the inhabitants of the peninsula, a kingdom, of Spain, and one of the component parts of that monarchy, situated between Lat. 40. 0. and 42. 51. N., and between Long. 2. 10. W. and 1. 45. E. It is bounded on the north by the Pyrenees, which separate it from France; east by Catalonia and Valencia; south by Valencia; and west by Navarre and the two Castiles. The length from north to south is 215 miles, and its breadth from 65 to 135 miles, with an area of 11,088 geographical square miles, and a population in 1849 of 847,105. In 1833 it was divided into the new provinces of Zaragoza, Huesca, and Teruel. The province is divided by the river Ebro into two nearly equal parts, which are distinguished as *Trans-ibero* and *Cis-ibero*. Its surface is very irregular: the western part, towards Old Castile, begins with the Sierra de Moncayo, but from the foot of these mountains to the Ebro the country is a continued level and fertile plain in the centre. To the south the ground rises gradually till it attains considerable elevation in the mountains near Cuença, in which are the sources of the most considerable rivers of Spain, some of which direct their courses to the Mediterranean, while otners force their way to the Atlantic. Mountains, branching from the Pyrenees, traverse the northern part, and it has likewise some mountains in the south; but these are of less elevation. The temperature of Aragon is extremely varied. In the north, near the Pyrenees, the climate is rigorous; while in the south, especially towards the Mediterranean, it is very mild.

The agricultural productions of the province necessarily vary with the variations in the elevation and aspect of the land. The greater part is appropriated to feeding flocks of Merino sheep, and their wool forms the most important of the productions of the province; in return for which they receive the manufactures of England and France. Wheat is grown more than sufficient for its own consumption, and it contributes to supply the neighbouring province of Navarre. Its wine and oil are generally more than its own demands require, and they are both of the best quality which Spain produces; but having none but difficult communication with any other country where these valuable articles are wanted, the cultivation of them languishes. Near the banks of the Ebro flax and hemp are grown in more than sufficient quantities for the domestic manufactures; and a supply of the latter is furnished to some of the maritime towns of Biscay, where it is preferred for cables to any other. The supply of horses and cows is not equal to the demands of the inhabitants, the deficiency being made up from the adjoining provinces. The mountainous parts abound with excellent ship-timber, but the badness of the roads prevents this branch of commerce from being carried on to any great extent.

The manufactures of the province are inconsiderable; that of silk, which was formerly extensive, has been gradually on the decline for some years. Manufactories for coarse cloths occupy the inhabitants of the city of Albarracin, and the large village of Tarazona; and some cloths of fine wool are made at Jaca, and some baize in its vicinity. Linen and sail-cloth are also made, but the quantity of each is small. There are iron manufactories on the mountains, where the abundance of trees calculated for making charcoal has introduced forges; but the badness of the roads checks their extension.

Aragon is not deficient in mineral riches, though the labour applied to them, as to most other objects in Spain, is in a very languid state. Near the Pyrenees, besides mines of iron, there are three mines of lead and one of copper, and, what is unique in Spain, a mine of cobalt. Besides these, there is a mine of alum near Alcaniz, which is very productive; and there are also quarries of marble and jasper.

At two leagues N.N.E. of Albarracin is the extraordinary fountain called Cella, at an elevation of 3700 feet above the sea. From this fountain the river Xiloca issues, and running through a beautiful country of 30 miles in extent, filled with inclosures, orchards, gardens, and vineyards, joins its waters, near Calatayud, to the more copious stream of the Xalon, which descends from Old Castile; and these united, lose their names by mingling their waters with the Ebro. Between the stream of the Xiloca and the mountains which separate Aragon from Molina, is a very extensive lake called Gallocanta, which covers about 6000 acres of land; and at a little distance from the lake are the ruins of the ancient city Bilbilis, which has derived celebrity from being the native place of the Roman poet Martial.

The principal river of Aragon is the Ebro, to which most of the other rivers in the province are tributary. (See EBRO.) The soil is generally dry; but the valleys are usually well-watered and fertile. The Imperial Canal of Aragon, which extends in the direction of the Ebro from Tudela almost to Sastago, is about eighty miles in length, nine feet in depth, and has an average breadth of sixty-nine feet. It is navigable for vessels of from 60 to 80 tons burthen. This great work was commenced by Charles V. in 1529, but remained unfinished for nearly 200 years.

The capital of Aragon is Zaragoza, a city of more than 40,000 inhabitants; for the description of which, with its memorable resistance to the French invaders, see ZARAGOZA. The other considerable cities and towns are Teruel, Daroca, Calatayud, Borja, Tarazona, Alcaniz, Caspe, Barbastro, Monzon, Huesca, and Jaca. At the most western part of the province a district called Cinco-villas is remarkably fruitful. The whole extent of 17,000 acres derives its fertility principally from an artificial canal, cut for the purpose of irrigation, called the royal canal of Tauste, by means of which the whole of the land may be flooded at pleasure.

The name of this kingdom was derived from the small but precipitous torrent Aragon, which rises in the Pyrenees, and, running from north to south, falls into the Ebro.

A great portion of the Pyrenees is in the province of Aragon. They run from east to west, presenting towards Spain the convex part of a kind of spherical segment, losing their height gradually towards each extremity. The highest point of this range of mountains, called by the French Mont Perdu, and by the Spaniards Monte Perdido and Las Tres Sorores, is visible from the city of Zaragoza. According to the actual measurement of the naturalist Ramond, who reached its summit in 1802, it is 11,430 feet above the level of the sea. Its top is constantly covered with snow, the permanent limits of which, on the same authority, are stated at 7750 feet of elevation. Before the measurement of Ramond, the point called Canigu was supposed to be the highest peak of this range, but it was thereby ascertained to be but 10,050 feet high.

There are at least fifty passes through the Pyrenees from France into Spain, but few of these are practicable except for the peasantry. The regular carriage roads over these mountains are the following:—1. The *Col de Pertus*, between Perpignan and Jonquera; 2. The pass of *Puy Moriens*, between the valley of Sagre and that of the Ariège; 3. The *Port de Confranc*, between Zaragoza and Pau; 4. The *Port de Roncevaux*, between Pamplona and St Jean; 5. The pass of *Bedassoa*, between Vittoria and Bayonne. From an accurate survey by the French engineers, it appeared there were upwards of eighty practicable passages,

of which twenty-eight would allow of cavalry, and seven of artillery and wheel-carriages. None of these had been ever examined by the Spanish government, though it was more than suspected that a very considerable contraband traffic had been conducted through these passes, in spite of the vigilance of the officers of revenue in both kingdoms.

Previous to the reign of Ferdinand and Isabella the political constitution of Aragon was the most liberal in Europe. Formally monarchical, its genius and maxims were purely republican. The kings, who were long elective, retained only the shadow of power; while its real exercise was in the hands of the Cortes; an assembly consisting of the nobility, the equestrian order, the representatives of the cities and towns, and the ecclesiastical order.

No law could pass without the assent of every member who had a right to vote. Without the permission of the Cortes no tax could be imposed, war could not be declared, nor peace concluded. Besides these, and other extraordinary privileges enjoyed by the Cortes, the Aragonese possessed another safeguard against despotic power in the election of a *Justiza*, or supreme judge, who acted as the guardian of the people, and the controller of the prince. He was the supreme interpreter of the laws, and was accountable to the Cortes alone for the manner in which he discharged the duties of his high office.—See *Robertson's History of Charles V.*, vol. i. § 3.

The history of Aragon before its union with Castile by the marriage of Ferdinand and Isabella, when it was merged in the kingdom of Spain, will be found in the general history of that country. It had, before this epoch, a succession of twenty sovereigns, from the year 1035 to 1516.—See *Zurita, Anales de Aragon; Viage de* Ponz; *Geografia de* Don Isidoro de Antillon; *Historia de la Economia Politica de Aragon*, por Don Ignacio de Asso.

ARAGONA, a town of Sicily, situated on a hill, seven miles N.N.E. of Girgenti. It is ill-built, but has some curious antiquities, and an old castle containing a fine gallery of pictures. In its vicinity is the celebrated mud-volcano of Maccaluba. Pop. 6500.

ARAGONITE, a carbonate of lime, with a small quantity of carbonate of strontia in its composition. See MINERALOGY.

ARAHAL, a town of Spain, in the province of Sevilla, 7 leagues south-east of the city of that name. The population, amounting to about 7000, is chiefly agricultural.

ARAL, a vast lake or inland sea, in Asia, about 200 miles eastward of the Caspian, between Lat. 40° and 47° N. Long. 57° and 61° E. Its form is irregularly oblong, extending from N.N.E. to S.S.W., about 290 miles by 130 from W. to E. It is separated from the Caspian by a plateau of the moderate elevation of 700 feet above that sea. Its western shores are steep and rocky; the southern and eastern are low and sandy, interspersed with marshes. Its waters are saline, but are readily drunk by horses. It abounds with the same species of fish as are found in the Caspian; and in both is found a species of seal which M. Vallenciennes has lately characterized as a peculiar species, different from the *Phoca Vitulina* of Linnæus and Pallas. In winter it is partially frozen, so that persons pass on the ice from the mouth of the river Sir to the town of Kourgrat. This sea receives two large rivers, the Amur, anciently the Oxus, from the west, and the Sir or Jaxartes from the east. Its name, in the language of the Kirghese-Tartars, is *Aral-Denghis*, or Sea of Islands, a group of which were described by the Russians in 1850 as near the middle of the sea, and have been named the Isles of Nicholas I., Constantine, Bellinghausen, and Lazareff. The level of the surface of this lake, compared with the Caspian and Black Sea, has not been well ascertained. Some barometrical measurements, little to be trusted, made its surface about 117 feet above the Caspian; but later, and seemingly more accurate observations, with the same instrument, reduce this difference to 34 feet. Indeed M. Von Humboldt is inclined to think that the surfaces of both seas are on the same level, and both on the same vast *Aralo-Caspian* depression of the Asiatic continent, which he reckons to occupy "a space of 18,000 square geographic leagues; that is to say, 900 square leagues greater than France, with a depression of about 81 English feet below the level of the Black Sea."—(*Asie Centrale*, ii. 311.) (T. S. T.)

ARALIACEÆ, a natural order of plants, of which the genus Panax is the chief. The Ginseng of the East is *P. fruticosa*, and there are several species of Panax in the New World and in Australia.

ARAM, the name given by the Hebrews to the extensive territory lying between Phœnicia, Palestine, Arabia Deserta, and the Tigris, and the mountain-range of Taurus. Aram, or Aramæa, seems to have corresponded generally to the Syria and Mesopotamia of the Greeks and Romans.

ARAMAIC LANGUAGE. This was divided into two dialects—the western and the eastern; the former is the Syriac, and the latter is the Chaldaic or Babylonic. Both, though nearly dead tongues, are yet used by some tribes about the ancient Aram, and in the hills near Mosul; and it was the most common dialect of the Jews after the Babylonian captivity till their dispersion by the Romans.

ARANDA DE DUERO, a town of Spain, in the province of Burgos, on the right bank of the river Duero. Pop. 4200. Long. 3. 40. 34. W. Lat. 41. 40. 12. N.

ARANGOES, pierced beads of rough carnelian, of various shapes and qualities, formerly imported from Bombay in considerable quantities for re-exportation to Africa. The best are barrel-shaped, from two to three inches long. Since the abolition of the slave-trade few have been imported.

ARANJUEZ (the ancient *Ara Jovis*), a town of Spain, in the province of New Castile, 28 miles S.S.E. of Madrid. It is situated in a fertile and well-watered valley on the left bank of the Tagus, immediately above the junction of that river with the Xarama, in Lat. 40. 1. 54. N. Long. 3. 37. 30. W. It is usually the residence of the Spanish Court from Easter till the end of June, during which time the population is increased from 4000 to about 12,000. The town is built in the Dutch style, with avenues of trees, and has numerous hotels, public gardens, theatres, and other places of amusement. The palace was begun by Philip II. and enlarged and embellished by his successors. The gardens are much admired for their rural beauties, fine shaded walks, fountains, and cascades. During the Peninsular war, this place suffered severely from the French. The treaty of 1772 between France and Spain, by which they pledged themselves to assist each other in opposing the English in America, was concluded here; and here, on the 18th of March 1808, broke out the insurrection which ended in the abdication of Charles IV. in favour of his son Ferdinand.

ARARAT (Turkish *Aghur Tagh*, Armenian *Macis*), a famous mountain of Armenia, at the point where the territories of Persia, Turkey, and Asiatic Russia meet—its principal summit being in Lat. 39. 42. N., Long. 44. 35. E. It consists of two immense conical masses, the summits of which, according to Parrot, are seven miles apart. They differ considerably in elevation, the summit of the Greater Ararat being 17,323 feet above the level of the sea, and 14,300 above the plain, while the Lesser Ararat is only 13,093 feet above sea level. The loftiest peak is covered with perpetual snow, which, however, does not form a glacier, and it reaches no lower than 14,100 feet above the sea. On the other summit it only lies from the end of October to the beginning of September. Ararat is isolated, except on the north, where it is connected with a chain extending along the valley of

the River Aras towards Erzeroum. It is a volcanic mountain; but there was no record of an eruption until 1840, when a vast column of vapour, mingled with dark smoke, was observed to proceed from a chasm on its flank to a great height; and an undulating motion of the earth, lasting only about two seconds, rolled from the mountain to the east and south-east. The village of Arguri and the monastery of St. James, with their inhabitants, were buried under the mass of stones and mud that was thrown out. This mountain is generally supposed to have been the place where Noah landed from the ark after the waters of the Flood had abated. The Jews, in the first century of the Christian era, identified the Ararat of Genesis with Armenia. The Armenians revere Mount Macis as the place of descent, and the Persians call it Koh-i-Nuh, or Noah's Mountain. Several attempts have been made to reach the top of Ararat, but few persons have succeeded in getting beyond the limit of perpetual snow. This is said to have been accomplished in 1829 by a German in the employment of Russia, and more recently in 1845 by Professor Abich; but the natives stoutly deny that either of these gentlemen reached the summit. In July 1856 a party of five English gentlemen succeeded in performing this feat.

ARAS, the ancient Araxes, a large river of Armenia, rises near the city of Erzeroum, and the sources of the Phrat or western branch of the Euphrates, and flows eastward for about 500 miles, when it joins the Kur. It is a very rapid and muddy river, with steep banks that prevent its waters being used for the purpose of irrigation. About 200 miles from its source it is joined by the Arpa-chai.

ARATUS, the son of Clinias, was born at Sicyon about 271 B.C. On the murder of his father by Abantidas, he was rescued from a similar fate by the care of a relative who conveyed him to Argos. At the age of twenty, with the assistance of some Argians, he deposed the tyrant Nicocles, and thus, without bloodshed, restored freedom to his native Sicyon. In 245 he was elected chief of the Achæan League, which office he frequently held in subsequent years; and he was mainly instrumental in confirming that great confederation which restored the liberties of Greece. (See Achæans.) In Aratus were combined many private virtues with splendid abilities; but he was more eminent as a statesman than as a general; for in his wars with the Ætolians and Spartans he was frequently unsuccessful. He died at the age of 58, as commonly reported by poison administered to him by the order of Philip of Macedon; but the symptoms of his disorder afford no certain grounds for such an assumption. His countrymen paid divine honour to his memory; and two yearly festivals (*Arateia*), were celebrated at Sicyon, one to commemorate his birth, the other his deliverance of the city from tyranny.—Plutarch, *Aratus* and *Agis;* Polybius ii. iv. vii. viii.

Aratus, a Greek poet, born at Soli, or Solæ, a town in Cilicia, which afterwards changed its name, and was called Pompeiopolis in honour of Pompey the Great. He flourished about the 124th, or, according to some, the 126th Olympiad, in the reign of Ptolemy Philadelphus, king of Egypt. He discovered in his youth a remarkable poignancy of wit, and capacity for improvement; and having received his education under Dionysius Heracleotes, a Stoic philosopher, he espoused the principles of that sect. Aratus was physician to Antigonus Gonatas, the son of Demetrius Poliorcetes, king of Macedon. His poem, entitled Φαινόμενα, describes the nature and motion of the fixed stars, and shows the particular influences of the heavenly bodies, with their various dispositions and relations. He wrote this poem in Greek verse. It was translated into Latin by Cicero, who tells us, in his first book *De Oratore*, that the verses of Aratus are very noble. This piece was translated by others as well as Cicero, there being a translation by Germanicus Cæsar, and another into elegant verse by Festus Avienus. An edition of the *Phænomena* was published by Grotius at Leyden, in quarto, in 1600, in Greek and Latin, with the fragments of Cicero's version, and the translations of Germanicus and Avienus; all which the editor has illustrated with curious notes. A valuable edition was published at Oxford, by Fell, in 1672, in 8vo; but the most complete is that of Buhle, published at Leipsic in 1801, in 2 vols. 8vo. There were several other works ascribed to Aratus, none of which have come down to us: Hymns to Pan; Astrology and Astrothesy; a composition of Antidotes; an Ἐπιθυτικόν on Theopropus; an Ἠθοποιά on Antigonus; an Epigram on Phila, the daughter of Antipater and wife of Antigonus; an Epicedium of Cleombrotus; a Correction of the Odyssey; and some Epistles in prose. Virgil, in his Georgics, has imitated or translated many passages from this author; and St Paul has quoted a passage of Aratus. It is in his speech to the Athenians (Acts xvii. 28), wherein he tells them that some of their own poets have said, Τοῦ γὰρ καὶ γένος ἐσμέν, For we are also his offspring. These words are the beginning of the fifth line of the *Phænomena.*

ARAUCANIA, an independent territory of South America, between Lat. 37. and 39. 50. S. and Long. 70. and 75. 20. W. It is bounded on the north by the river Biobio, which separates it from Chili, south by the Valdivia, east by the Andes, and west by the Pacific Ocean.

The Araucanians are remarkable for the fierce and almost uninterrupted struggle they have maintained for upwards of 300 years against the encroachments of the Spaniards on their territory. They are of moderate stature, strong, muscular, and well-built, with a light copper complexion, lank hair, oval faces, prominent cheek-bones, the nose somewhat flat, the eyes small, and expressive of vivacity. Their general aspect indicates some degree of sternness and resolution; they are bold and intrepid in war, patiently enduring fatigue, and fearlessly exposing their lives.

The country is divided into four tetrarchies, each governed by a *Toqui.* Each tetrarchy is divided into five provinces, governed by an *Apo-ulmen*, and each of the provinces is subdivided into nine districts, severally presided over by an *Ulmen.* The *Toquis* are independent of each other, but form a federal union for the public welfare. They have no maintenance from the state, nor are their subjects bound to render them any kind of personal service, except in time of war. A great council, composed of *Toquis*, *Apo-ulmens*, and *Ulmens* is convened upon any emergency. In time of war, a commander-in-chief is chosen, generally from the *Toquis*, but should none of them possess the requisite qualifications, one of the inferior rulers is elected. The others swear obedience to him, and furnish him with their contingent of men. Before the arrival of the Spaniards their army of course consisted of infantry only; but they soon saw the value of cavalry, and in a short time they could muster a considerable body of horse. The cavalry are armed with lances and swords; the infantry with pikes and clubs mounted with iron. Formerly they used the sling and bow, but these were soon laid aside. Every soldier is the rightful possessor of the booty he can seize; but a fair division is made of the plunder taken in common, the toqui himself receiving no larger share than a private soldier.

Their religious system is somewhat similar to their political government. They believe in a supreme Being, whom they call the Spirit of Heaven, and who is the great toqui of the universe. Under this spirit there are *apo-ulmens*, or inferior deities, and in the lowest rank are *ulmens* or genii. They have no temples, idols, or priests, and only sacrifice on solemn occasions. They believe in the immortality of the soul. Polygamy prevails among them; a man being allowed as many wives as he can purchase. Their principal

wealth consists in flocks and herds, and their industry is confined to husbandry. See AMERICA, CHILI.

ARAUCARIA, a beautiful genus of the Coniferæ. It differs from other firs by its broad shining leaves. The first species was found in the mountains of Araucania; and the two other known species are found in various parts of South America, and in some islands in the Pacific. *A. excelsa* grows freely in sheltered situations in Britain, where it is called *Norfolk Island Pine*.

ARAUSIO, *Civitas Arausiensis* or *Arausicorum*, or *Colonia Secundanorum;* so called, because the veterans of the second legion were there settled; now *Orange*, in the west of Provence, on an arm of the river Aigues. See ORANGE.

ARAVULLI, a range of mountains in Rajpootana, extending about 300 miles from north-east to south-west, where they are separated from the Vindhya mountains by the valley of the river Mhye. The Aravulli form a series of ridges, covering a breadth of from 6 to 60 miles, with a general elevation of 3600 feet. They rise abruptly from the western desert, but fall gradually towards the east. Their general geological character is of primitive formation, with rocks of granite, compact dark blue slate, gneiss, and sienite; and the summits of the diverging ranges, west of Ajmere, are quite dazzling, says Colonel Tod, not with snow like the Himalayas, but with enormous masses of vitreous rose-coloured quartz. To the north of Komulmair, 25° north latitude, two of their ridges form a continuous table-land between them, 6 to 20 miles in width, as far as Ajmere, where it breaks up from the tabular form, and sends off numerous branches of low rocky hills, through Jeypour and Alwar, which reach the Jumnah in the vicinity of Delhi. That part of the range between Komulmair and Ajmere, called Mairwarra, or the region of hills, is inhabited by the Mairs, a branch of the Mairas, one of the aboriginal tribes of India, who have lived for ages by robbery, being at constant war with their Rajpoot neighbours. They have yielded, however, to British influence, and give fair promise of becoming a civilized and industrious people.

ARBACES was governor of Media under Sardanapalus king of Assyria. Disgusted by the effeminacy of the king, he stirred up his people to revolt, and dethroned Sardanapalus, who thereupon burnt himself in his palace. Arbaces founded the monarchy of the Medes, which lasted 317 years under eight kings, till Astyages was expelled by Cyrus. Arbaces reigned 28 years, and died B.C. 848. (Diodorus, ii.) Herodotus gives a different account; but the authority of Ctesias, whose original work has perished, is followed by most ancient historians. (V. Paterculus i. 6; Justin, i. 3; Strabo, xvi. 737.)

ARBALEST, or CROSS-BOW. See CROSS-BOW.

ARBE, anciently ARBA, an island and city of Illyria, in the Gulf of Quarnaro. Of this island, which has been but slightly noticed by geographers, there is a full account in the Abbé Fortis's *Account of Dalmatia.* The appearance of the island is exceedingly pleasant. On the east it has a very high mountain, at the foot of which the rest of the island is extended to the westward, and divided into beautiful and fruitful plains interspersed with little hills fit to bear the richest products. At the extremity that looks to the north a delightful promontory, called Loparo, stretches into the sea: it is crowned with little hills, which almost inclose a fine cultivated plain. Near this promontory are the two small islands of S. Gregorio and Goli. The city stands between two harbours on a rising ground almost peninsular.

ARBELA, now ARBIL or ERBIL, a town of Asiatic Turkey, to the east of the Tigris, in Long. 44. 5. E. and Lat. 36. 11. N., 40 miles east of Mosul. It appears to have been once a very large town, but is now quite decayed. It is built on an artificial mound, about 150 feet high, surrounded by a wall inclosing about a thousand houses, and there are about 500 more at its foot. Its inhabitants are Kurds and Turks. It is famous in history as having given its name to the last decisive battle, B.C. 331, between Alexander the Great and Darius Codomannus, the last king of Persia. The battle was fought in the plain of Gaugamela, fifty miles distant, and Alexander pursued the fugitives to Arbela. See GREECE.

ARBERG, a town of Switzerland, in the canton of Bern, with a handsome castle, where the bailiff resides. It is seated on the river Aar, in a kind of island; and since 1830 has been fortified. Long. 7. 15. E. Lat. 47. 0. N. Pop. 850.

ARBITRARY, that which is left to choice or arbitration, or not fixed by any positive law or injunction.

ARBITRARY *Punishment*, in *Law*, denotes such punishments as are by statute left to the discretion of the judge. It is a general rule in arbitrary punishments, that the judge cannot inflict death. Hence all punishments that are not capital have acquired the name of *arbitrary punishments*, even although they be expressly pointed out by statute.

ARBITRATION, a term derived from the nomenclature of the Roman law, and applied to an arrangement for taking and abiding by the judgment of a selected person in some disputed matter, instead of carrying it to the established courts of justice. Arrangements for avoiding the delay and expense of litigation, and referring a dispute to friends or neutral persons, are a natural practice, of which traces may be found in any state of society; but it is to the Justinian jurisprudence that we owe it as a system which has found its way into the practice of European nations in general, and has even evaded the dislike of the English common lawyers to the civil law. The eighth section of the fourth book of the Pandects is devoted to this subject, and may be consulted through the commentary of Heineccius, or a more minute critical inquiry by Gerard Noodt, in his commentary on this section (Opera, ii. 135). Almost all the advantages, as well as the defects of the system in modern practice, seem to have been anticipated by the Roman jurists. Thus it is shown that voluntarily selected judges can only properly decide questions which the parties themselves could settle by giving and taking, and that they ought not to be authorized to deal with criminal inquiries or public questions; while, by excluding matters of personal status, such as marriage or legitimacy, the Roman jurists anticipated the principle, that even private questions which may affect the public morals or policy cannot be thus extrajudicially disposed of. They dwell on the principal advantage of the system in excluding appeal from the arbiter's decision on any such ground as erroneous law, or false views of the influence of well-investigated facts. But, on the other hand, they discuss, with their usual scientific subtlety, the many defects, such as excess of authority, neglect of form, and partiality in receiving pleadings or evidence, and the like, by which arbitrations become vitiated; and thus these jurists at once suggest what is ever the defect of a system of arbitration, that the more it performs its function of doing justice, the more it becomes what the established tribunals of the country ought to be, and fosters two systems of judicature where one should be sufficient. Some of the civilians make a distinction between the *arbitrator*, the name technically applicable to a person voluntarily chosen by parties to decide disputes, and the *arbiter* an officer to whom the prætor remitted questions of fact as to a jury. In this sense arbiters appear to have been employed as a substitute for jury trial in some of the old provincial laws of France; and hence, perhaps, it comes that, by a very remarkable provision in the French code of commerce, all questions between partners touching the partnership must be referred to arbitration. In the code of civil procedure, the title *des arbitrages* is treated so fully and minutely, as very forcibly to convey the impression of a separate system of voluntary jurisdiction being created for performing what ought to be accomplished by the ordinary tribunals in a well-regulated judicial system. In Scotland, the practice of arbitration has been

imported from the Roman law without requiring, as in England, statutory intervention. From the peculiarities of the Scottish system of registration, the decree-arbitral, or decision of the arbiter, when recorded in pursuance of the consent of the parties in their contract of arbitration, or submission, can be enforced as the decree of a court. (J. H. B.)

ARBITRATION, in the *Law of England* (according to Blackstone), is "where the parties, injuring and injured, submit all matters in dispute, concerning any personal chattels or personal wrong, to the judgment of two or more *arbitrators;* who are to decide the controversy: and if they do not agree, it is usual to add, that another person be called in as *umpire* (*imperator*), to whose sole judgment it is then referred: or frequently there is only one arbitrator originally appointed." The decision must be in writing (unless otherwise expressly provided in the submission), and is called an *award;* and thereby the question is as fully determined, and the right transferred or settled, as it could have been by the agreement of the parties or the judgment of a court of law or equity.

There were, however, many inconveniences attending this mode of proceeding; and in the year 1698, the legislature accordingly interfered and passed the act 9th and 10th Will. III., cap. 15, which enacted that, "for promoting trade, and rendering the awards of arbitrators the more effectual in all cases, for the final determination of controversies referred to them by merchants and traders, or others, concerning matters of account or trade, or other matters;" all merchants and others, desiring to end any controversy, suit, or quarrel (for which there is no other remedy but by personal action or suit in equity), by arbitration, may agree that their submission of their suit to the award or umpirage of any person shall be made a rule of any of the courts of record, and may insert such agreement in their submission; which agreement being proved by the affidavit of one of the witnesses thereto, the court shall make a rule that such arbitration or umpirage pursuant to such submission shall be conclusive; and, after such rule made, the parties disobeying the award shall be liable to be punished, as for a contempt of court; unless such award shall be set aside, as procured by corruption or undue means in the arbitrators or umpire, to be proved on oath to the court, before the last day of the next term after the award is made.

An application for an attachment for not performing an award, may be resisted at any time for defects appearing on the face of the award itself; for such an award, after that time, might be pleaded in bar to any action brought upon it, although it cannot be *set aside* for such defects after the end of the next term. Submissions of disputes to arbitration may be by consent of the parties, or with the interposition of a court of justice; by rule of court, or order of a judge, when a cause is pending, either by bond, agreement in writing, or by parol. A verbal agreement, however, to abide by an award cannot be made a rule of court. Nor can matters purely criminal be submitted to the decision of an arbitrator. And by the 12th and 13th Vict. c. 45, §§ 12–15, the provisions of the former statutes as to arbitrations are extended to "controversies and disputes, for which the remedy is by appeal to a court of general or quarter sessions of the peace." Lastly, although the right of real property cannot pass by a mere award, yet if a party be awarded to convey land, and refuse, he will be liable to an action, or to an attachment for not performing the award.

The agreement of reference must be expressed with great care and accuracy;—provisions should be inserted giving power to either party to make the submission a rule of court, to enable the court to refer the matter back to the same or to another arbitrator; and in case of the death of either party before award, for its making and delivery to his representatives; and also as to the costs, which are usually directed to be in the discretion of the arbitrator as to those of the reference, and as to those of the cause to abide the event of the award; and a certain day should be appointed on or before which the arbitrator is to make his award, with a power to such arbitrator to enlarge the time.

When arbitrators have the power of electing an umpire, they may choose him, and call in his assistance as soon as they begin to take the subject into consideration; and this is the more convenient practice, as it secures a decision upon a single investigation of the controversy.

As to the award; it must be in pursuance of the submission, and embrace all the matters submitted, and not extend beyond it in the subject-matter, in persons, in time, or in particular circumstances; it must be certain; it must make a final end and determination of all matters contained in the submission; it must be mutual, that is, it must not be entirely of things to be performed by one party, without such things being in satisfaction of the matters in difference; and finally, it must not be unreasonable, illegal, or impossible to be effectuated.

Formerly, a submission to arbitration, being a mere authority, might be revoked at any time before execution, by an instrument of as high a nature as that by which the submission was created. But now, by the Law Amendment Act (3d and 4th Will. IV., cap. 42), the submission to arbitration by *Rule of Court*, or *Judge's order*, or *order of Nisi Prius*, or if there be an *agreement to make the submission a Rule of Court*, cannot be revoked by any party thereto, without leave of the court or a judge. The death, however, of either party, before award is a revocation of the authority, unless otherwise provided in the submission; and so also is the marriage of a female before award; the marriage operating as a civil death to all her rights as a *feme sole.*

Under this statute the attendance of witnesses, or production of documents before the arbitrator, may be compelled by a rule of court, or order of a judge, on payment of expenses and loss of time; and the arbitrators are empowered to administer oaths to the witnesses, where it is so agreed or ordered by the rule or order of reference. Any witnesses failing to attend are deemed to be guilty of contempt of court, or giving false evidence guilty of perjury.

The court or judge may also, in the cases within the statute, enlarge the time for an arbitrator to make his award.

As to the mode of enforcing an award, see ATTACHMENT. (R. M—M.)

ARBOIS, a town of France, department of Jura, formerly Franche-Compté, famous for its wines. Pop. 6370. Long. 5. 47. E. Lat. 46. 55. N.

ARBON, a town of Switzerland, canton of Thurgau, chief of the circle of the same name. It contains 1100 inhabitants, and has some trade in cotton goods. It is on the Lake of Constance. Long. 9. 25. E. Lat. 42. 27. N.

ARBOR, in *Mechanics*, the axis or spindle of a machine, as of a crane or a windmill. Also that part of a machine which sustains the rest.

ARBROATH, or ABERBROTHOCK, a seaport and manufacturing town of Scotland, in the county of Forfar, 17 miles north-east of Dundee, 15 miles E.S.E. of Forfar, and 60 miles N.N.E. from Edinburgh, situated on the North Sea, at the mouth of the river Brothock, 12 miles north-west of the Bell-Rock lighthouse, in Lat. 56. 34. N. Long. 2. 35. W.

Arbroath was early celebrated for its abbey, founded by William the Lion in 1178, and dedicated to the famous Thomas à Becket, archbishop of Canterbury. It was created a royal burgh in 1186, and the charter was renewed in 1589. King John of England granted it very unusual privileges; for, by charter under the great seal, he exempted it *a teloniis et consuetudine* in every part of England, except London. The founder of this abbey was buried there, but there are no remains of his tomb. The monks belonged to

the Tyronensian order, and came from Kelso, the abbot of which place declared them to be free from his jurisdiction. In 1320, a convention of the Scottish nobles was held in this abbey by Robert I., where a letter was addressed to the pope, praying him to admonish and exhort Edward II. not to invade their territory. This letter is remarkable for the spirit and independence of its style, considering the time and circumstances under which it was written.—See Hailes' *Annals of Scotland.*

In 1394, an agreement was entered into by John Geddie, the abbot, and the burgesses of Arbroath, by which the former obliged himself and his successors to maintain a sufficient harbour at their own expense. The last abbot was the too famous Cardinal Beaton, at the same time archbishop of St Andrews. This abbey, like many other buildings of the same class, fell a sacrifice to the zeal of the Reformers in 1560; but its former magnificence and splendour are attested by the remains of its walls, cloisters, towers, piers, and the fine window of the chancel.

At the commencement of the eighteenth century, Arbroath was a place of little importance, but it has gradually been enlarged and improved, and is now a flourishing town, with considerable manufactures of hemp and flax. The principal manufacture is that of linen, which gives employment to a great part of its population. It has seventeen spinning mills, several bleach-works, two tanneries, two iron founderies, several ship-building yards (with a patent slip), rope-works, and breweries. Among its public buildings are the town-hall, prison, trades-hall, and the parish church, to which a handsome spire 150 feet high has lately been added; two chapels of ease, three Free churches, an Episcopal, a Catholic, an Independent, and several Secession chapels. It has three branch banks, a savings bank, three news rooms, a subscription and a mechanics' library, and an academy. A weekly newspaper, the *Arbroath Guide,* is published on Saturday. During the course of last century, the Abbot's harbour was superseded by a more commodious one a little to the west of the other, which has lately been much enlarged and improved at a cost of L.50,000. A neat signal tower 50 feet in height, with an excellent telescope, communicates with the Bell-Rock lighthouse; and on its north pier is a fixed red light, at an elevation of 24 feet, which is visible eight miles off. Its imports are hemp, flax, vitriol, manganese, coal, &c.; its exports, paving-flags, barley, potatoes, fish, &c. In 1849, there were 116 vessels, of the aggregate burden of 12,609 tons, belonging to the port; and in that year the gross amount of customs' duty received at its port was L.13,946, being upwards of L.2000 above that of the preceding year. It is connected with Forfar by a railway, which also unites it with the Scottish Midland and the Aberdeen lines; and it communicates with Dundee by the Arbroath and Dundee Railway. The municipal government is vested in a provost, two bailies, a treasurer, a dean of guild, and twelve councillors; and it has seven incorporated trades. Arbroath unites with Forfar, Montrose, Brechin, and Bervie, in sending a member to parliament. By the census of 1851, Arbroath had 1737 inhabited houses, and 17,008 inhabitants. The market-day is Saturday; and fairs are held on the last Saturday of January, the first Saturday after Whitsunday, the 1st of July if a Saturday, or on the first Saturday thereafter, and the first Saturday after Martinmas.

ARBURG, or Aarburg, a city of Switzerland, in the circle of Zoffingen, and canton of Aargau. It stands at the confluence of the rivers Aar and Wigger, and has been almost entirely rebuilt since its destruction by fire in 1840. In 1850 it contained 1650 inhabitants, who manufacture cotton goods and hosiery. Conspicuous on the height above is the citadel, built in 1660, now a military storehouse.

ARBUTHNOT, Alexander, principal of the university of Aberdeen in the reign of James VI. of Scotland, was born in the year 1538. He studied first at Aberdeen, and was afterwards sent over to France, where, under the famous Cujacius, he applied himself to the study of the civil law. In the year 1563 he returned to Scotland and took orders. Whether he was ordained by a bishop or by presbyters is a matter of uncertainty. In 1568 he was appointed minister of Arbuthnot and Logie Buchan; and in the following year Mr Alexander Anderson being deposed, he was made principal of the King's College at Aberdeen in his room. In the General Assembly which met at Edinburgh in the years 1573 and 1577 he was chosen moderator, and to the end of his life was an active supporter of the Reformed religion. He died in 1583, in the forty-fifth year of his age, and was buried in the College church of Aberdeen. It was by him that Buchanan's *History of Scotland,* published in 1582, was edited. The only production of his own is his *Orationes de Origine et Dignitate Juris,* printed at Edinburgh in 1572, 4to. His contemporary Thomas Maitland wrote a copy of Latin verses on the publication of this book: they are printed in the *Delit. Poet. Scot.* The same collection contains an elegant epitaph on him by Andrew Melvil.

Arbuthnot, *John,* M.D., the son of an Episcopal clergyman in Scotland, was born soon after the Restoration, at Arbuthnot, near Montrose. Having gone through a course of academical studies and obtained the degree of doctor of physic at Aberdeen, he went to London, where he began to display his talents in teaching mathematics, in which he was well skilled. *An Examination of Dr Woodward's Account of the Deluge,* &c., in 1697, first made him known to the learned world. This performance was received with great applause; and in 1700 a treatise *On the Usefulness of Mathematical Learning* increased his reputation. A very interesting paper *On the Regularity of the Births of both Sexes,* demonstrating from authentic proofs the universal similarity which is observed by nature in this circumstance, and drawing from these several political and moral inferences, which he presented to the Royal Society, procured his election in 1704 into that body. Meanwhile he was acquiring considerable eminence in his own profession, and was appointed physician extraordinary to Prince George of Denmark, and shortly afterwards one of the physicians in ordinary to Queen Anne. He was admitted in 1710 a fellow of the college. He formed about this period a very intimate acquaintance with Pope, Gay, and Swift, which lasted with unabating affection during the rest of his life. In 1714, in co-operation with Pope and Swift, he engaged in writing a satire upon all the abuses of science in every branch, under the form of the history of a fictitious character, and in the grave ironical style. The plan was never finished, but the *Memoirs of Martinus Scriblerus,* published in Pope's works, form a part, of which much is the performance of Dr Arbuthnot. It is very probable that the whole of the first book is of his composition, in which the profound knowledge that is displayed, and the good-natured pleasantry with which the satire is directed, has gained it the character of one of the most original, learned, and interesting pieces in the English language. Those parts which relate to anatomy, the manners and customs of antiquity, and logic, are particularly his performance.

On the death of Queen Anne, which was a serious blow to his personal and political views, Arbuthnot visited Paris, where he spent some time. On his return he retired from St James's, where his services were no longer required, and attended to the practice of his profession. His literary pursuits were carried on at the same time with undiminished ardour, though considerable intervals elapsed between the publication of his works. A work entitled *Tables of Ancient Coins, Weights, and Measures,* explained and exemplified in several dissertations, appeared in 1727, in a 4to volume,

which is the chief of his serious performances. Although there are inaccuracies in it which could hardly be avoided in so intricate a subject, it is a work of great merit, and is still considered as a standard authority, though the more recent work of Hussey is generally preferred. A treatise *On the Nature and Choice of Aliments*, which was published in 1732, and another published in 1733, *On the Effects of Air on Human Bodies*, finish the list of his acknowledged works. Respecting his humorous works, which were the productions of his leisure hours, they are so confounded with those of his contemporaries, that it is not easy to distinguish them. But a piece which, independent of any other, would rank him among the best humorous writers in the English language, entitled the *History of John Bull*, is confidently ascribed to him. It is written with great wit and humour, and all the circumstances and characters are most admirably adapted. Among his several avowed ironical pieces are, *A Treatise concerning the Altercation or Scolding of the Ancients*, and the *Art of Political Lying*.

In the year 1751 there were published two small volumes, entitled *The Miscellaneous Works of Dr Arbuthnot;* but the greater part of what they contain is denied by his son to be of his composition. Through all his pieces of this kind there runs a vein of good-natured pleasantry; and this tends to confirm the character given of him by Swift, "He has more wit than we all have, and his humanity is equal to his wit."

In these occupations he passed his days, amid all the pleasures that can render domestic life happy, in the affection and estimation of his friends, beloved and esteemed by all his literary associates, who have each taken great pains to celebrate their mutual friendship. Swift, in one of his poems, sincerely laments that he is

> Far from his kind Arbuthnot's aid,
> Who knows his art, but not his trade.

Pope has dedicated to him an epistle called a *Prologue to the Satires*. Of his two sons, he witnessed the death of one; and the other, with several daughters, survived him. At length, from an inveterate asthma, he fell into a dropsical disorder; and in order to try the effect of a change of air, he repaired to Hampstead, though without any hope of recovery. Returning to his house in London, he died February 27, 1734–5.

ARBUTUS, a genus of the natural order Ericaceæ, and some of them very ornamental shrubs in our pleasure grounds. This is especially the case with *A. Unedo*, a plant indigenous in southern Europe, which stands our British climate well, attaining a height of 20 feet, and bears a berry somewhat resembling a strawberry. A specimen of *A. Andrachne*, even higher still, remarkable for the iron-brown colour of its epidermis, which it annually sheds, is growing in the open air at Otterspool near Liverpool.

ARC, Joan of (*Jeanne d'Arc*), generally called the *Maid of Orleans*, one of the most famed heroines in the annals of history, was born about the beginning of the fifteenth century at Domremy, near Vaucouleurs, in Lorraine, where her father, a peasant named Jacques d'Arc, resided. When she was able in the least degree to earn a sustenance for herself, her parents, who were poor, put her to service at a small inn, where she performed several offices more properly belonging to the other sex, such as riding the horses to water, and attending them in the fields, and many other similar services. At the time when Charles VII. was reduced to a very low condition, and the greatest part of his country had been overrun by the English, Joan, probably then at the age of 27 or 28, imagined herself favoured with heavenly visions, in one of which she was commanded by St Michael to go immediately to the relief of Orleans, at that time closely besieged by the English army, and then to procure the consecration of the king at Rheims. In February 1429 her parents took her to the governor of Vaucouleurs, named Baudricourt, who at first held her pretended inspiration to be no more than an idle tale, and treated it with contempt; but at last, induced by her entreaties, he sent her to Chinon, where the king then was, in order that she might be introduced to him. Charles, that he might test her alleged powers, determined to present her to a company of his nobles, where no mark of dignity tended to distinguish him from them; and it is asserted that she immediately recognized him, and informed him of secrets which he had endeavoured to conceal from every person. She boldly engaged to accomplish the two objects of her mission, and required that they should arm her with a consecrated sword which lay in the church of St Catherine of Fierbois; and although she had never seen it, she accurately described every particular concerning it. The manner in which she acted inspired many with confidence; and certain doctors of the church were appointed to examine into the nature of her inspiration, and matrons to give proofs of her virginity. The report which they gave was very favourable; but being next put into the hands of the parliament, they treated her as frantic, and demanded that she should show them a miracle. She answered, that although she had not any at that time to present, she would soon accomplish one at Orleans. At length being fully armed and mounted, she was sent to Orleans along with the army destined for its relief. Her exemplary enthusiasm reanimated the soldiery, and the camp was soon freed from disorder and intemperance. Entering Orleans, she introduced a convoy; and boldly attacking the English in their forts, she routed them with great slaughter, and struck them with such a panic that they were even obliged to raise the siege with precipitate haste. The dignity of a superior mind and an exalted heroism reigned through all her actions. Various other successes followed in a short time, and the dismayed English everywhere fled before the hand of a conquering enemy whom they had but lately contemned. Joan now thinking it proper to perform her other promise of crowning the king at Rheims, proceeded with him as he marched through the kingdom, in order to receive submission of the towns, which he did without any opposition. Arriving at Rheims, the keys of the city were delivered to him; and, entering the town, he was anointed with the holy oil of Clovis, and crowned, Joan standing by his side in full armour, and displaying her consecrated banner. Charles filled with gratitude for her important services, ennobled her family, and conferred upon it the title of *the Sys*, with an adequate estate in hand. The two objects of her mission being now accomplished, Joan prepared to retire into the country; but Dunois, the general, being sensible of her importance on account of her pretended inspiration, endeavoured to persuade her to remain in arms until the English should be fully driven from the country; which by his persuasions he effected. Advised by him, she cast herself into Compiegne, then closely besieged by the English and the Duke of Burgundy. Having there made a sally upon the enemy, she drove them from their intrenchments; but being basely deserted by her followers, she was taken prisoner. The English, with a malignant spirit of revenge, resolved to show no mercy to their heroic captive. The Duke of Bedford the regent, having ransomed her from the captors, appointed a criminal prosecution against her, upon the charges of employing sorcery and magic, and of being impious. He was joined in the accusation by the clergy, and by the university of Paris. Joan was carried in irons before an ecclesiastical commission at Rouen, where several capricious interrogatories were put to her during a trial of about four months, to which she answered with steadiness and gravity. Among several other questions, she was interrogated why she had assisted at the coronation of Charles with the standard in her hand. She boldly replied, "Because the person who shared in the danger had a right

Arch.

to share in the glory." Her defence was not so strong concerning her pretended inspiration and visions, which were the most dangerous points of the attack. She appealed to the pope upon being accused on these grounds of impiety and heresy, but her appeal was not allowed. At length she was condemned of being a blasphemer and sorceress, and accordingly delivered over to the power of the civil magistrate. A view of the dreadful punishment that awaited her at last overpowered her resolution, and she endeavoured to escape it, by making a disavowal of her pretended revelations, and a full renunciation of her errors. Her sentence was then changed into perpetual imprisonment; but this punishment did not assuage the fury of her barbarous enemies. They craftily laid a man's dress in her chamber; and Joan, induced by the sight of an apparel in which she had gained so much honour, put it on; and upon being discovered, her enemies condemned her to the stake, interpreting the action into a relapse of heresy. She suffered her punishment in June 1431, at the market-place of Rouen, with great firmness; and even the English themselves beheld the scene with tears. Her unjust and cruel death was an indelible stigma on the character of her prosecutors. Charles did nothing towards avenging her cause; but ten years afterwards contented himself with procuring the restoration of her memory by the pope, and a reversion of the process. She was styled in that act a "martyr to her religion, her country, and her king." In their enthusiastic admiration, her countrymen were not so slow in honouring her memory. Many marvellous stories were related by them concerning her death. Some supposed that she was not actually dead, and continually expected that, as formerly, she would come, and at their head lead them on to victory. A consistent and uniform judgment respecting the actions and address of this personage cannot be made by posterity. That she gave herself up to the influence of a heated fancy, and that she was confident in the idea of her divine inspiration, and that this notion was so improved by certain favourites of Charles as to excite the emotions of the public, seems to be the most probable supposition.

Arcade ‖ Arch.

ARCADE, in *Architecture*, is used to denote any opening formed by an arch in the wall of a building.

ARCADIA, a very mountainous country in the centre of Peloponnesus, bounded on the north by Achaia, east by Argolis, west by Elis, and south by Messenia and Laconia. Its greatest length was about 50 miles, and its breadth from 35 to 41 miles. The Alpheus and its tributaries were its principal rivers. The Arcadians derived their origin from the eponymous hero Arcas; and they are called by the Greek writers autochthones, or aborigines. Their great tutelary deity was Pan, who presided over rural affairs. The Arcadians were a simple and frugal people, and especially fond of music, which they cultivated with great success. When the rest of Peloponnesus was conquered by the Dorians, they maintained their independence. They were originally governed by kings; but about the year 670 B.C. they abolished monarchy, and their several cities—the most important of which were Mantinea, Orchomenus, Tegea, Pheneos, and Psophis—became independent republics. The Arcadians joined the Achæan League, and finally submitted to the Romans.

ARCESILAUS, a celebrated Greek philosopher, about 300 years before the Christian era, was born at Pitane, in Æolis. He founded the New Academy, called also the *Second* or *Middle* school. He was a man of great erudition, and had many disciples. The middle school laid it down as a principle, that we could know nothing, nor even assure ourselves of the certainty of this position; from whence they inferred that we should affirm nothing, but always suspend our judgment. They held that a philosopher was able to dispute upon every subject, and bring conviction with him, even upon contrary sides of the same question; for there are always reasons of equal force both in the affirmative and negative of every argument. According to this doctrine, neither our senses nor even our reason are to have any credit; and therefore, in common affairs, we are to conform ourselves to received opinions. Arcesilaus died in his 76th year in a fit of intoxication, and was succeeded by his disciple Lacydes, who met a similar fate.

ARCH.

Arch defined.

1. Arch, in *Building*, is an artful disposition and adjustment of several stones or bricks, generally in a bow-like form, by which their weight produces a mutual pressure and abutment; so that they not only support each other, and perform the office of an entire lintel, but may be extended to any width, and made to carry the most enormous weights.

History of architecture connected with arches.

2. In those mild climates which seem to have been the first inhabited parts of this globe, mankind stood more in need of shade from the sun than of shelter from the inclemency of the weather. A very small addition to the shade of the woods served them for a dwelling. Sticks laid across from tree to tree, and covered with brushwood and leaves, formed the first houses in those delightful regions. As population and the arts improved, these huts were gradually refined into commodious dwellings. The materials were the same, but more artfully put together. At last agriculture led the inhabitants out of the woods into the open country. The connection between the inhabitant and the soil became now more constant and more interesting. The wish to preserve this connection was natural, and fixed establishments followed of course. Durable buildings were more desirable than those temporary and perishable cottages—stone was substituted for timber.

But as these improved habitations were gradual refinements on the primitive hut, traces of its construction remained, even when the choice of more durable materials made it in some measure inconvenient. Thus it happened that while a plain building, intended for accommodation only, consisted of walls, pierced with the necessary doors and windows, an ornamented building had, superadded to these essentials, columns, with the whole apparatus of entablature borrowed from the wooden building, of which they had been essential parts, gradually rendered more suitable to the purposes of accommodation and elegance.

3. This view of ornamental architecture will go far to account for some of the more general differences of national style which may be observed in different parts of the world. The Greeks borrowed many of their arts from their Asiatic neighbours, who had cultivated them long before.

4. The ancient Egyptian architecture seems to be a refinement on the hut built of clay, or unburnt bricks, mixed with straw—everything is massive.

5. The Arabian architecture seems a refinement on the tent. A mosque is like a little camp, consisting of a number of little bell tents, stuck close together round a great one. A caravansery is a court surrounded by a row of such tents, each having its own dome. The Greek church of St Sophia at Constantinople has imitated this in some degree; and the copies from it, which have been multiplied in Russia as the sacred form for a Christian church, have added to the original model of clustered tents in the

strictest manner. We are sometimes disposed to think that the painted glass (a fashion brought from the East) was an imitation of the painted hangings of the Arabs.

6. The Chinese architecture is an evident imitation of a wooden building. Sir George Staunton says, that the singular form of their roofs is a *professed* imitation of the cover of a square tent.

In the stone buildings of the Greeks, the roofs were imitations of the wooden ones; hence the lintels, flying cornices, ceilings in compartments, &c.

7. The pediment of the Greeks seems to have suggested the greatest improvement in the art of building. In erecting their small houses, they could hardly fail to observe occasionally, that when two rafters were laid together from the opposite walls, they would, by leaning on each other, give mutual support, as in Plate XLVIII. fig. 1. Nor is it unlikely that such a situation of stones as is represented in fig. 2 would not unfrequently occur by accident to masons. This could hardly fail of exciting a little attention and reflection. It was a pretty obvious reflection, that the stones A and C, by overhanging, leaned against the intermediate stone B, and gave it some support, and that B cannot get down without thrusting aside A and C, or the piers which support them. This was an approach to the theory of an arch; and if this be combined with the observation of fig. 1, we get the disposition represented in fig. 3, having a perpendicular joint in the middle, and the *principle of the arch* is completed. Observe that this is quite different from the principle of the arrangement in fig. 2. In that figure the stones act as wedges, and one cannot get down without thrusting the rest aside. The same principle obtains in fig. 4, consisting of five arch-stones; but in fig. 3 the stones B and C support each other by their mutual pressure (independent of their own weight), arising from the tendency of each lateral pair to fall outwards from the pier. This is the principle of the arch, and would support the key-stone of fig. 4, although each of its joints were perpendicular, by reason of the great friction arising from the horizontal thrust exerted by the adjoining stones.

This was a most important discovery in the art of building; for now a building of any width may be roofed with stone.

8. We are disposed to give the Greeks the merit of this discovery; for we observe arches in the most ancient buildings of Greece, such as the temple of the sun at Athens, and of Apollo at Didymos—not indeed as roofs to any apartment, nor as parts of the ornamental design, but concealed in the walls, covering drains or other necessary openings; and we have not found any *real* arches in any monuments of ancient Persia or Egypt. Sir John Chardin speaks of numerous and extensive subterranean passages at Tchelminar, built of the most exquisite masonry, the joints so exact, and the stones so beautifully dressed, that they look like one continued piece of polished marble; but he nowhere says that they are arched—a circumstance which we think he would not have omitted: no arched door or window is to be seen. Indeed one of the tombs is said to be arch-roofed, but it is all of one solid rock. No trace of an arch is to be seen in the ruins of ancient Egypt; even a wide room is covered with a single block of stone. In the pyramids, indeed, there are two galleries whose roofs consist of many pieces; but their construction puts it beyond doubt that the builder did not know what an arch was; for it is covered in the manner represented in fig. 5, where every projecting piece is more than balanced behind. Yet there are perfect arches, both circular and pointed, in the pyramidal remains at Djebel-el-Berkel, the ancient Napata, in Meroe, the cradle of Egyptian art. The arched dome, however, seems to have arisen in Etruria, and originated in all probability from the employment of the augurs, whose business it was to observe the flight of birds. Their stations for this purpose were *templa*, so called *a templando*, on the summits of hills. To shelter such a person from the weather, and at the same time allow him a full prospect of the country around him, no building was so proper as a dome set on columns; which accordingly is the figure of a temple in the most ancient monuments of that country. We do not recollect a building of this kind in Greece except that called the *Lanthorn of Demosthenes*, but this is covered by a single stone. In the later monuments and coins of Italy or of Rome we commonly find the Etruscan dome and the Grecian temple combined; and the famous Pantheon was of this form, even in its most ancient state.

9. It does not appear that the arch was considered as a part of the *ornamental* architecture of the Greeks during the time of their independency. It is even doubtful whether it was employed in roofing their temples. In none of the *ancient* buildings where the roof is gone can there be seen any rubbish of the vault or mark of the spring of the arch. It is not unfrequent, however, after the Roman conquests, and may be seen in Athens, Delos, Palmyra, Balbeck, and other places. It is very frequent in the magnificent buildings of Rome; such as the Coliseum, the baths of Diocletian, and the triumphal arches, where its form is evidently made the object of attention. But its chief employment was in bridges and aqueducts; and it is in these works that its immense utility is the most conspicuous: for by this happy contrivance a canal or a road may be carried across any stream, where it would be almost impossible to erect piers sufficiently near to each other for carrying lintels. Arches have been executed 130 feet wide, and their execution demonstrates that they may be made four times as wide.

10. As such stupendous arches are the greatest performances of the masonic art, so they are the most difficult and delicate. When we reflect on the immense quantity of materials thus suspended in the air, and compare this with the small cohesion which the firmest cement can give to a building, we shall be convinced that it is not by the force of the cement that they are kept together; they stand fast only in consequence of the proper balance of all their parts. Therefore, in order to erect them with a well-founded confidence of their durability, this balance should be well understood and judiciously employed. We doubt not but that this was understood in some degree by the engineers of antiquity; but they have left us none of their knowledge. They must have had a great deal of mechanical knowledge before they could erect the magnificent and beautiful buildings whose ruins still enchant the world; but they kept it among themselves. We know that the Dionysiacs of Ionia were a great corporation of architects and engineers, who undertook and even monopolized the building of temples, stadiums, and theatres, precisely as the fraternity of masons in the middle ages monopolized the building of cathedrals and conventual churches. Indeed the Dionysiacs resembled the mystical fraternity now called free-masons in many important particulars. They allowed no strangers to interfere in their employment; they recognised each other by signs and tokens; they professed certain mysterious doctrines, under the tuition and tutelage of Bacchus, to whom they built a magnificent temple at Teos, where they celebrated his mysteries as solemn festivals; and they called all other men profane because not admitted to these mysteries. But their chief mysteries and most important secrets seem to be their mechanical and mathematical sciences, or all that academical knowledge which forms the regular education of a civil engineer.

We know that the temples of the gods and the theatres required an immense apparatus of machinery for the celebration of some of their mysteries; and that the Dionysiacs contracted for those jobs, even at far distant places, where they had not the privilege of building the edifice which was to contain them. This is the most likely way of explaining the very small quantity of mechanical knowledge that is to be met with in the writings of the ancients. Even Vitruvius does not appear to have been of the fraternity, and speaks of the Greek architects in terms of respect next to veneration. The *Collegium Murariorum*, or incorporation of masons at Rome, does not seem to have shared the secrets of the Dionysiacs.

11. The art of building arches has been most assiduously cultivated by the associated builders of the middle ages of the Christian church, both Saracens and Christians, and they seem to have indulged in it with fondness: they multiplied and combined arches without end, placing them in every possible situation.

12. Having studied this branch of the art of building with so much attention, they were able to erect the most magnificent buildings with materials which a Greek or Roman architect could have made little or no use of. There is infinitely more scientific skill displayed in a Gothic cathedral than in all the buildings of Greece and Rome. Indeed these last exhibit very little knowledge of the mutual balance of arches, and are full of gross blunders in this respect; nor could they have resisted the shock of time so long, had they not been almost solid masses of stone, with no more cavity than was indispensably necessary.

13. Anthemius and Isidorus, whom the Emperor Justinian had selected as the most eminent architects of Greece, for building the celebrated church of St Sophia at Constantinople, seem to have known very little of this matter. Anthemius had boasted to Justinian that he would outdo the magnificence of the Roman Pantheon, for he would hang a greater dome than it aloft in the air. Accordingly he attempted to raise it on the heads of four piers, distant from each other about 115 feet, and about the same height. He had probably seen the magnificent vaultings of the temple of Mars the Avenger, and the temple of Peace at Rome, the thrusts of which are withstood by two masses of solid wall, which join the side walls of the temple at right angles, and extend sidewise to a great distance. It was evident that the walls of the temple could not yield to the pressure of the vaulting without pushing these immense buttresses along their foundations. He therefore placed four buttresses to aid his piers. They are almost solid masses of stone, extending at least ninety feet from the piers to the north and to the south, forming as it were the side walls of the cross. They effectually secured them from the thrusts of the two great arches of the nave which support the dome; but there was no such provision against the push of the great north and south arches. Anthemius trusted for this to the half dome which covered the semicircular east end of the church, and occupied the whole eastern arch of the great dome. But when the dome was finished, and had stood a few months, it pushed the two eastern piers with their buttresses from the perpendicular, making them lean to the eastward, and the dome and half dome fell in. Isidorus, who succeeded to the charge on the death of Anthemius, strengthened the piers on the east side by filling up some hollows, and again raised the dome. But things gave way before it was closed; and while they were building in one part, it was falling in in another. The pillars and walls of the eastern semicircular end were much shattered by this time. Isidorus seeing that they could give no resistance to the push which was so evidently directed that way, erected some clumsy buttresses on the east wall of the square which surrounded the whole Greek cross, and was roofed in with it, forming a sort of cloister round the whole. These buttresses, spanning over this cloister, leaned against the piers of the dome, and thus opposed the thrusts of the great north and south arches. The dome was now turned for the third time, and many contrivances were adopted for making it extremely light It was made offensively flat, and, except the ribs, was roofed with pumice stone; but, notwithstanding these precautions, the arches settled so as to alarm the architects, and they made all sure by filling up the whole from top to bottom with arcades in three stories. The lowest arcade was very lofty, supported by four noble marble columns, and thus preserved in some measure the church in the form of a Greek cross. The story above formed a gallery for the women, and had six columns in front, so that they did not bear fair on those below. The third story was a dead wall filling up the arch, and pierced with three rows of small, ill-shaped windows. In this unworkmanlike shape it has stood till now, and is the oldest church in the world; but it is an ugly mis-shapen mass, more resembling an overgrown potter's kiln, surrounded with furnaces pierced and patched, than a magnificent temple. We have been thus particular in our account of it, because this history of the building shows that the ancient architects had acquired no distinct notions of the action of arches. Almost any mason of our time would know, that as the south arch would push the pier to the eastward, while the east arch pushed it to the southward, the buttress which was to withstand these thrusts must not be placed on the south side of the pier, but on the south-east side, or that there must be an eastern as well as a southern buttress.

14. No such blunders are to be seen in a Gothic cathedral. Some of them appear, to a careless spectator, to be very massive and clumsy; but when judiciously examined, they will be found very bold and light, being pierced in every direction by arcades; and the walls are divided into cells like a honeycomb, so that they are very stiff, while they are very light.

Dr Hooke's principle of arches

15. About the middle, or rather towards the end, of last century, when the Newtonian mathematics opened the road to true mechanical science, the construction of arches engrossed the attention of the first mathematicians. The first hint of a principle that we have met with is Dr Hooke's assertion, that the figure into which a chain or rope, perfectly flexible, will arrange itself when suspended from two hooks, is, when inverted, the proper form for an arch composed of stones of uniform weight. This he affirmed on the principle, that the figure which a flexible festoon of heavy bodies assumes, when suspended from two points, is, when inverted, the proper form of an arch of the same bodies, touching each other in the same points; because the force with which they mutually press on each other in this last case are equal and opposite to the forces with which they pull at each other in the case of suspension.

This principle is strictly just, and may be extended to every case which can be proposed. We recollect seeing it proposed in very general terms in 1759, when plans were forming for Blackfriars Bridge in London; and since it is perhaps equal in practical utility to the most elaborate investigations of the mathematicians, our readers will not be displeased with a more particular account of it in this place.

explained

16. Let ABC (fig. 6) be a parcel of magnets of any size and shape, and let us suppose that they adhere with great force by any points of contact. They will compose such a flexible festoon as we have been speaking of if

suspended from the points A and C. If this figure be inverted, preserving the same points of contact, they will remain in equilibrio. It will indeed be that kind of equilibrium which will admit of no disturbance, and which may be called a *tottering equilibrium*. If the form be altered in the smallest degree, by varying the points of contact (which indeed are points in the *figure of equilibration*), the magnets will no more recover their former position than a needle, which we had made to stand on its point, will regain its perpendicular position after it has been disturbed.

But if we suppose planes *d e*, *f g*, *h i*, &c. drawn through the points of mutual contact *a*, *b*, *c*, each bisecting the angle formed by the lines that unite the adjoining contacts (*f g*, for example, bisecting the angle formed by *a b*, *b c*), and if we suppose that the pieces are changed for others of the same weights, but having flat sides, which meet in the planes *d e*, *f g*, *h i*, &c., it is evident that we shall have an arch of equilibration, and that the arch will have some stability, or will bear a little change of form without tumbling down: for it is plain that the equilibrium of the original festoon obtained only in the points *a*, *b*, *c*, of contact, where the pressures were perpendicular to the touching surfaces; therefore, if the curve *a*, *b*, *c*, still passes through the touching surfaces perpendicularly, the conditions that are required for equilibrium still obtain. The case is quite similar to that of the stability of a body resting on a horizontal plane. If the perpendicular through the centre of gravity falls within the base of the body, it will not only stand, but it will require some force to push it over. In the original festoon, if a small weight be added in any part, it will change the form of the curve of equilibration a little, by changing the points of mutual contact. This new curve will gradually separate from the former curve as it recedes from A or C. In like manner, when the festoon is set up as an arch, if a small weight be laid on any part of it, it will bring the whole to the ground, because the shifting of the points of contact will be just the contrary to what it should be to suit the new curve of equilibration; but if the same weight be laid on the same part of the arch now constructed with flat joints, it will be sustained if the new curve of equilibration still passes through the touching surfaces.

17. These conclusions, which are very obviously deducible from the principle of the festoon, show us, without any further discussion, that the longer the joints are, the greater will be the stability of the arch, or that it will require a greater force to break it down. Therefore it is of the greatest importance to have the arch-stones as long as economy will permit; and this was the great use of the ribs and other apparent ornaments in the Gothic architecture. The great projections of those ribs augmented their stiffness, and enabled them to support the unadorned compartments of the roof, composed of very small stones, seldom above six inches thick. Many old bridges are still remaining, which are strengthened in the same way by ribs.

Having thus explained, in a very familiar manner, the stability of an arch, we proceed to give the same popular account of the general application of the principle.

and applied.

18. Suppose it be required to ascertain the form of an arch which shall have the span AB (fig. 7), and the height F 8, and which shall have a road-way of the dimensions CDE above it. Let the figure ACDEB be inverted, so as to form a figure A *c d e* B. Let a chain of uniform thickness be suspended from the points A and B, and let it be of such a length that its lower point will hang at, or rather a little below, *f*, corresponding to F. Divide AB into a number of equal parts, in the points 1, 2, 3, &c. and draw vertical lines, cutting the chain in the corresponding points 1, 2, 3, &c. Now take pieces of another chain, and hang them on at the points 1, 2, 3, &c. of the chain A *f* B. This will alter the form of the curve. Cut or trim these pieces of chain, till their lower ends all coincide with the inverted road-way *c d e*. The greater lengths that are hung on in the vicinity of A and B will pull down these points of the chain, and cause the middle point *f* (which is less loaded) to rise a little, and will bring it near to its proper height.

It is plain that this process will produce an arch of perfect equilibration; but some further considerations are necessary for making it exactly suit our purpose. It is an arch of equilibration for a bridge that is so loaded that the weight of the arch-stones is to the weight of the matter with which the haunches and crown are loaded, as the weight of the chain A *f* B is to the sum of the weights of all the little bits of chain very nearly. But this proportion is not known beforehand; we must therefore proceed in the following manner:—Adapt to the curve produced in this way a thickness of the arch-stones as great as are thought sufficient to insure stability; then compute the weight of the arch-stones, and the weight of the gravel or rubbish with which the haunches are to be filled up to the road-way. If the proportion of these two weights be the same with the proportion of the weights of chain, we may rest satisfied with the curve now found; but if different, we can easily calculate how much must be added equally to or taken from each appended bit of chain, in order to make the two proportions equal. Having altered the appended pieces accordingly, we shall get a new curve, which may perhaps require a very small trimming of the bits of chain to make them fit the road-way. This curve will be very near to the curve wanted.

We have practised this method for an arch of 60 feet span and 21 feet high, the arch-stones of which were only two feet nine inches long. It was to be loaded with gravel and shivers. We made a previous computation, on the supposition that the arch was to be nearly elliptical. The distance between the points 1, 2, 3, &c. were adjusted, so as to determine the proportion of the weights of chain agreeable to the supposition. The curve differed considerably from an ellipse, making a considerable angle with the verticals at the spring of the arch. The real proportion of the weights of chain, when all was trimmed so as to suit the road-way, was considerably different from what was expected. It was adjusted. The adjustment made very little change in the curve. It would not have changed it two inches in any part of the real arch. When the process was completed, we constructed the curve mathematically. It did not differ sensibly from this mechanical construction. This was very agreeable information; for it showed us that the first curve, formed by about two hours' labour, on a supposition considerably different from the truth, would have been sufficiently exact for the purpose, being in no place three inches from the accurate curve, and therefore far within the joints of the intended arch-stones. Therefore this process, which any intelligent mason, though ignorant of mathematical science, may go through with little trouble, will give a very proper form for an arch subject to any conditions.

19. The chief defect of the curve found in this way is a want of elegance, because it does not spring at right angles to the horizontal line; but this is the case with all curves of equilibration, as we shall see by and by. It is not material; for, in the very neighbourhood of the piers, we may give it any form we please, because the masonry is solid in that place; nay, we apprehend that a deviation from the curve of equilibration is proper. The construction of that curve supposes that the pressure on every part of the arch is vertical; but gravel, earth, and rub-

Arch.

bish, exert somewhat of a hydrostatical pressure laterally in the act of settling, and retain it afterwards. This will require some more curvature at the haunches of an arch to balance it; but what this lateral pressure may be, cannot be deduced with confidence from any experiments that we have seen. We are inclined to think, that if, instead of dividing the horizontal line AB in the points 1, 2, 3, &c. we divide the chain itself into equal parts, the curve will approach nearer to the proper form.

Theory founded on this principle.

20. After this familiar statement of the general principle, it is now time to consider the theory founded on it more in detail. This theory aims at such an adjustment of the position of the arch-stones to the load on every part of the arch, that all shall remain in equilibrio, although the joints be perfectly polished and without any cement. The whole may be reduced to two problems. The first is to determine the vertical pressure or load on every point of a line of a given form, which will put that line in equilibrio. The second is to determine the form of a curve which shall be in equilibrio when loaded in its different points, according to any given law.

The whole theory is deducible from one principle, which will be found fully developed in the article Roof. It is this: when an assemblage of beams or other pieces of solid matter AB, BC, CD, DE, fig. 8, freely movable about its angles as so many joints, is retained in equilibrium by the joint effect of the pressures produced by the weight of its parts, the thrust at any angle, if estimated in a horizontal direction, is the same throughout, and may be represented by any horizontal line BT; and that if a vertical line QS be drawn through T, the thrust exerted at any angle D by the piece CD, in its own direction, will then be represented by BR, drawn parallel to CD; and in like manner, that the thrust in the direction ED is represented by BS, &c.; and, lastly, that the vertical thrust or loads at each angle B, C, D, by which all these other pressures are excited, are represented by the portions QC, CR, RS, of the vertical intercepted by those lines; that is, all these pressures are to the uniform horizontal thrust as the lines which represent them are to BT. The horizontal thrust, therefore, is a very proper unit, with which we may compare all the others. Its magnitude is easily deduced from the same proposition; for QS is the sum of all the vertical pressures of the angles, and therefore represents the weight of the whole assemblage. Therefore as QS is to BT, so is the weight of the whole to the horizontal thrust.

21. To accommodate this theory to the construction of a curvilinear arch vault, let us first suppose the vault to be polygonal, composed of the chords of the elementary arches. Let AVE (fig. 12) be a curvilinear arch, of which V is the vertex, and VX the vertical axis, which we shall consider as the axis or abscissa of the curve, while any horizontal line, such as HK, is an ordinate to the curve. About any point C of the curve, as a centre, describe a circle BLD, cutting the curve in B and D. Draw the equal chords CB, CD. Draw also the horizontal line CF, cutting the circle in F. Describe a circle BCDQ passing through B, C, D. Its centre O will be in a line COQ, which bisects the angle BCD; and C *c*, which touches this circle in C, will bisect the angle *b* C *d*, formed by the equal chords BC, CD. Draw CLP perpendicular to *cb*, and DP perpendicular to CD, meeting CL in P. Through L draw the tangent GLM, meeting CD in G, and the vertical line CM in M. Draw the tangent F *a*, cutting the chords BC, CD, in *b* and *d*, and the tangent to the circle BCDQ in *c*. Lastly, draw *d* N parallel to *bc*.

From what will be demonstrated in the article Roof, it appears that if BC, CD be two pieces of an equilibrated heavy polygon, and if CF represent the horizontal thrust in every angle of the polygon, C *d* and C *b* will severally represent the thrusts exerted by the pieces DC, BC, and that *bd*, or CN, will represent the weight lying on the angle BCD, by which those thrusts are balanced. In the mean time the reader may, without that article, understand the nature of the equilibrium in the following manner. Produce *d* C to *o*, so that C *o* may be equal to C *d*. Draw *bn* to the vertical parallel to *d* C, and join *no*. It is evident that *bno*C is a parallelogram, and that *n* C ($=bd$) = CN. Now the thrust or support of the piece BC is exerted in the direction C *b*, while that of DC is exerted in the direction C *o*. These two thrusts are equivalent to the thrust in the diagonal C *n*; and it is with this compound thrust that the load or vertical pressure CN is in *immediate* equilibrium.

22. Because *b*CL, NCF are right angles, and FCL is common to both, the angles *b*CF and MCL are equal; therefore the right-angled triangles *b*CF and MCL are similar. And since CF is equal to CL, C*b* is equal to CM. It is evident that the triangles GCM and *d*CN are similar. Therefore CG : C*d* = CM : CN = C *b* : C N. Therefore we have $\text{CN} = \frac{\text{C}b \times \text{C}d}{\text{CG}}$. But because CDP and CLG are right angles, and therefore equal, and the angle GCP is common to the two triangles GCL, PCD, and CD is equal to CL, we have CG equal to CP; therefore $\text{CN} = \frac{\text{C}b \times \text{C}d}{\text{CP}}$. Also, since CDP is a right angle, DP meets the diameter in Q, the opposite point of the circumference, and the angle DQC is equal to DC*c* or *c*C*b* (because *b*C*d* is bisected by the tangent), that is, to PCQ (because the right angles *b*CP, *c*CO are equal, and *c*DP is common). Therefore PQ is equal to PC; and if PO be drawn perpendicular to CQ, it will bisect it, and O is the centre of the circle BCDQB.

Now let the points B and D continually approach to C (by diminishing the radius of the small circle), and ultimately coincide with it. It is evident that the circle BCDQ is ultimately the equicurve circle, and that PC ultimately coincides with OC, the radius of curvature. Also C*b*×C*d* becomes ultimately Cc^2. Therefore CN, the vertical load on any point of a curve of equilibration, is $= \frac{\text{C}c^2}{\text{Rad. Curv.}}$.

It is further evident that CF is to C*c* as radius to the secant of the elevation of the tangent above the horizon. Therefore we have the load on any point of the curve always proportional to $\frac{\text{Sec.}^2\text{ Elev.}}{\text{Rad. Curv.}}$.

This load on every elementary arch of the wall is commonly a quantity of solid matter incumbent on that element of the curve, and pressing it vertically; and it may be conceived as made up of a number of heavy lines standing vertically on it. Thus, if the element E*e* of the curve were lying horizontally, a little parallelogram RE*er* standing perpendicularly on it would represent its load. But as this element E*e* has a sloping position, it is plain that, in order to have the same quantity of heavy matter pressing it vertically, the height of the parallelogram must be increased till it meets in *ε*, the line R *ε* drawn parallel to the tangent EG. It is evident that the angle RE*ε* is equal to the angle AEG. Therefore we have ER : E*ε* = Rad. : Sec. Elev.

If therefore the arch is kept in equilibrio by the vertical pressure of a wall, we must have the height of the wall above any point proportional to $\frac{\text{Sec.}^3\text{ Elev.}}{\text{Rad. of Curv.}}$.

Corollaries.

23. *Corol.* 1. If OS be drawn perpendicular to the

vertical CS, CS will be half the vertical chord of the equicurve circle. The angle OCS is equal to cCF, that is, to the angle of elevation. Therefore 1 : Sec. Elev. = CS : CO, and the secant of elevation may be expressed by $\frac{\text{CO}}{\text{CS}}$, and its cube by $\frac{\text{CO}^3}{\text{CS}^3}$. Therefore the height of wall is proportional to $\frac{\text{CO}^3}{\text{CS}^3 \times \text{CO}}$, or to $\frac{\text{CO}^2}{\text{CS}^3}$, or $\frac{\text{CO}^2}{\text{CS}^2 \times \text{CS}}$, or to $\frac{\text{Sec.}^2 \text{ of Elev.}}{\text{Vert. Chord of Curve}}$.

Corol. 2. If we make the arch VC $= z$, the abscissa VH $= x$, the ordinate HC $= y$, the radius osculi CO $= r$, and the $\frac{1}{2}$ vertical chord CS $= s$, the height of wall pressing on any point is proportional to $\frac{dz^3}{rdy^3}$; or to $\frac{dz^2}{sdy^2}$, or $\frac{dx^2 + dy^2}{sdy^2}$. Therefore, when the equation of the curve is given, and the height of wall on any one point of it is also given, we can determine it for any other point; for the equation of the curve will always give us the relation of dz, dx, dy, and the value of r or s. This may be illustrated by an example or two. For this purpose it will generally be most convenient to assume the height above the vertex V for the unit of computation. The thickness of the arch at the crown is commonly determined by other circumstances. At the vertex the tangent to the arch is horizontal, and therefore the cube of the secant is unity or 1. Call the height of wall at the crown H, and let the radius of curvature in that point be R, and its half-chord R (it being then coincident with the radius), and the height on any other point h; we have $\frac{1}{\text{R}} : \frac{dz^3}{rdy^3} = \text{H} : h$, and $h = \text{H} \times \frac{dz^3}{dy^3} \times \frac{\text{R}}{r}$. The other formula gives $h = \text{H} \times \frac{dz^2}{dy^2} \times \frac{\text{R}}{s}$.

Illustrated by examples.

24. *Ex.* 1. Suppose the arch to be a segment of a circle, as in fig. 10, where AE is the diameter, and O the centre. In this arch the curvature is the same throughout, or $\frac{\text{R}}{r} = 1$. Therefore $h = \text{H} \times \frac{dz^3}{dy^3}$, or $= \text{H} \times$ Cube Sec. Elev.

This gives a very simple calculus. To the logarithm of H add thrice the logarithm of the secant of elevation. The sum is the logarithm of h.

It gives also a very simple construction. Draw the vertical CS, cutting the horizontal diameter in S. Draw ST, cutting the radius OC perpendicularly in T. Draw the horizontal line Tz, cutting the vertical in z. Join zO. Make Cu = Vv, and draw ux parallel to zO: Cc must be made = Cx. The demonstration is evident.

It is very easy to see that if CV is an arch of 60°, and Vv is $\frac{1}{14}$th of VO, the points v and c will be on a level; for the secant of CV is twice CO, and therefore Cc is eight times Vv, which is $\frac{1}{7}$th of VH.

The dotted line $vgcf$ is drawn according to this calculus or construction. It falls considerably below the horizontal line in the neighbourhood of c; and then, passing very obliquely through c, it rises rapidly to an immeasurable height, because the vertical line through A is its asymptote. This must evidently be the case with every curve which springs at right angles with a horizontal line.

It is plain that if vV be greater, all the other ordinates of the curve $vgcf$, resting on the circumference AVE, will be greater in the same proportion, and the curve will cut the horizontal line drawn through v in some point nearer to v than c is. Hence it appears that a circular arch cannot be put in equilibrio by building on it up to a horizontal line, whatever be its span, or whatever be the thickness at the crown. We have seen that when this thickness is only $\frac{1}{14}$th of the radius, an arch of 120 degrees will be too much loaded at the flanks. This thickness is much too small for a bridge, being only $\frac{1}{25}$th of the span CM, whereas it should have been almost double of this, to bear the inequalities of weight that may occasionally be on it. When the crown is made still thinner, the outline is still more depressed before it rises again. There is therefore a certain span, with a corresponding thickness at the crown, which will deviate least of all from a horizontal line. This is an arch of about 45 degrees, the thickness at the crown being about one fourth of the span, which is extravagantly great. It appears in general, therefore, that the circle is not a curve suited to the purposes of a bridge or an arcade, which requires an outline nearly horizontal.

Ex. 2. Let the curve be a parabola AVE (fig. 14), of which V is the vertex, and DG the directrix. Draw the diameters DCF, GVN, the tangents CK, VP, and the ordinates VF and CN. It is well known that GV is to DC as VP² to CK², or as CN² to CK². Also 2 GV is the radius of the osculating circle at V, and 2 DC is one half of the vertical chord of the osculating circle at C.

Therefore CN² : CK² (or $dy^2 : dz^2$) = R : s; and $s = \frac{dz^2}{dy^2}$R. But Cc, or $h = \text{H} \times \frac{dz^2\text{R}}{dy^2 s}$. Therefore $h = \text{H} \times \frac{dz^2\text{R}}{dy^2 \frac{dz^2}{dy^2}\text{R}} = \text{H} \times \frac{dz^2\text{R}}{dz^2\text{R}} = \text{H}$. Therefore C$c$ = vV.

It follows from this investigation, that the back or extrados of a parabolic arch of equilibration must be parallel to the arch or soffit itself; or that the thickness of the arch, estimated in a vertical direction, must be equal throughout; or that the extrados is the same parabola with the soffit or intrados.

We have selected these two examples merely for the simplicity and perspicuity of the solutions, which have been effected by means of elementary geometry only, instead of employing the analytical value of the radius of the osculatory circle, viz. $\frac{dz^3}{dyd^2x - dxd^2y}$, which would have involved us at last in the doctrine of second fluxions. We have also preferred simplicity to elegance in the investigation, because we wish to instruct the practical engineer who may not be a proficient in the higher mathematics.

To find the form of an arch when the figure of its back is given.

25. The converse of the problem, namely, to find the form of the arch when the figure of the back of it is given, is the most usual question of the two, at least in cases which are most important and most difficult. Of these, perhaps, bridges are the chief. Here the necessity of a road-way, of easy and regular ascent, confines us to an outline nearly horizontal, to which the curve of the arch must be adapted. This is the most difficult problem of the two; and we doubt whether it can be solved without employing infinite approximating series instead of accurate values.

Let ave (fig. 9) be the intended outline or extrados of the arch AVE, and let v Q be the common axis of both curves. From c and C, the corresponding points, draw the ordinates ch, CH. Let the thickness vV at the top be a, the abscissa vh be $= u$, and VH $= x$, and let the equal ordinates ch, CH, be y, and the arch VC be z.

Arch.

Then, by the general theorem, $cC = \frac{dz^3}{rdy^3}$, r being the radius of curvature. This, by the common rules, is $= \frac{dz^3}{dyd^2x - dxd^2y}$. This gives us $cC \div \frac{dyd^2x - dxd^2y}{dy^3}$, or $= \frac{dyd^2x - dxd^2y}{dy^3} \times C$; where C is a constant quantity, found by taking the real value of cC in V, the vertex of the curve. But it is evident that it is also $= a + x - u$. Therefore $a + x - u = \frac{dyd^2x - dxd^2y}{dy^3} \times C = \frac{C}{dy} \times$ fluxion of $\frac{dx}{dy}$.

If we now substitute the true value of u (which is given because the extrados is supposed to be of a known form), expressed in terms of y, the resulting equation will contain nothing but x and y, with their first and second fluxions, and known quantities. From this equation the relation of x and y must be found by such methods as seem best adapted to the equation of the extrados.

Fortunately the process is more simple and easy in the most common and useful case than we should expect from this general rule; we mean the case where the extrados is a straight line, especially when this is horizontal. In this case u is equal to o.

Pl. XLIX. Fig. 6. *Ex.* To find the form of the balanced arch AVE, having the horizontal line cv for its extrados.

Keeping the same notation, we have $u = o$, and therefore

$$a + x = \frac{C}{dy} \times \text{fluxion of } \frac{dx}{dy}.$$

Assume $dy = \frac{dx}{v}$; then $\frac{dx}{dy} = v$, and $\frac{C}{dy} \times$ fluxion of $\frac{dx}{dy} = \frac{Cvdv}{dx}$, that is, $a + x = \frac{Cvdv}{dx}$. Therefore $adx + xdx = Cvdv$; and by taking the fluents, we have $2\,ax + x^2 = Cv^2$; and $v = \sqrt{\frac{2\,ax + x^2}{C}}$. Consequently, $dy = \frac{\sqrt{C}dx}{\sqrt{2\,ax + x^2}}$ $\left(\text{being} = \frac{dx}{v}\right)$. Taking the fluent of this, we have $y = \sqrt{C} \times L\,(2\,a + 2\,x + 2\sqrt{2\,ax + x^2})$. But at the vertex, where $x = o$, we have $y = \sqrt{C} \times L\,(2\,a)$. The corrected fluent is therefore $y = \sqrt{C} \times L\frac{a + x + \sqrt{2\,a\,x + x^2}}{a}$.

It only remains to find the constant quantity C. This we readily obtain by selecting some point of the extrados where the values of x and y are given by particular circumstances of the case. Thus, when the span 2 s and height h of the arch are given, we have

$s = \sqrt{C} \times L\left(\frac{a + h + \sqrt{2\,a\,h + h^2}}{a}\right)$, and consequently $\sqrt{C} = \frac{s}{L\left(\frac{a + h + \sqrt{2\,a\,h + h^2}}{a}\right)}$. Therefore

$$\text{the general value of } y = s \times \frac{L\left(\frac{a + x + \sqrt{2\,a\,x + x^2}}{a}\right)}{L\left(\frac{a + h + \sqrt{2\,a\,h + h^2}}{a}\right)}$$

$$= \frac{s}{L\frac{a + h + \sqrt{(2ah + h^2)}}{a}} \times L\frac{a + x + \sqrt{2\,a\,x + a^2}}{a}.$$

26. As an example of the use of this formula, we subjoin a table calculated by Dr Hutton of Woolwich, for an arch, the span of which is 100 feet, and the height 40, which are nearly the dimensions of the middle arch of Blackfriars Bridge in London.

y	x	y	x	y	x
0	6,000	21	10,381	36	21,774
2	6,035	22	10,858	37	22,948
4	6,144	23	11,368	38	24,190
6	6,324	24	11,911	39	25,505
8	6,580	25	12,489	40	26,894
10	6,914	26	13,106	41	28,364
12	7,330	27	13,761	42	29,919
13	7,571	28	14,457	43	31,563
14	7,834	29	15,196	44	33,299
15	8,120	30	15,980	45	35,135
16	8,430	31	16,811	46	37,075
17	8,766	32	17,693	47	39,126
18	9,168	33	18,627	48	41,293
19	9,517	34	19,617	49	43,581
20	9,934	35	20,665	50	46,000

The figure for this proposition is exactly drawn according to these dimensions, that the reader may judge of it as an object of sight. It is by no means deficient in gracefulness, and is abundantly roomy for the passage of craft; so that no objection can be offered against its being adapted on account of its mechanical excellency.

Defects of the Catenarean curve.

The reader will perhaps be surprised that we have made no mention of the celebrated Catenarean curve, which is commonly said to be the best form for an arch; but a little reflection will convince him, that although it is the only form for an arch consisting of stones of equal weight, and touching each other only in single points, it cannot suit an arch which must be filled up in the haunches, in order to form a road-way. He will be more surprised to hear, after this, that there is a certain thickness at the crown, which will put the Catenarea in equilibrio, even with a horizontal road-way; but this thickness is so great as to make it unfit for a bridge, being such that the pressure at the vertex is equal to the horizontal thrust. This would have been about 37 feet in the middle arch of Blackfriars Bridge. The only situation, therefore, in which the Catenarean form would be proper, is an arcade carrying a height of dead wall; but in this situation it would be very ungraceful. Without troubling the reader with the investigation, it is sufficient to inform him, that in a Catenarean arch of equilibration the abscissa VH is to the abscissa $v\,h$ in the constant ratio of the horizontal thrust to its excess above the pressure on the vertex

27. Thus much will serve, we hope, to give the reader a clear notion of this celebrated theory of the equilibrium of arches, one of the most delicate and important applications of mathematical science. Volumes have been written on the subject, and it still occupies the attention of mechanicians. But we beg leave to say, with great deference to the eminent persons who have prosecuted this theory, that their speculations have been of little service, and are little attended to by the practitioner. Nay, we may add, that Sir Christopher Wren, perhaps the most accomplished architect that Europe has seen, seems to have thought it of little value; for, among the fragments which have been preserved of his studies, there are to be seen some imperfect dissertations on this very subject, in which he takes no notice of this theory, and considers the balance of arches in quite another way. These are collected by the author of the account of Sir Christopher Wren's family. This man's great sagacity,

and his great experience in building, and still more his experience in the repairs of old and crazy fabrics, had shown him many things very inconsistent with this theory, which appears so specious and safe. The general facts which occur in the failure of old arches are highly instructive, and deserve the most careful attention of the engineer; for it is in this state that their defects, and the process of nature in their destruction, are most distinctly seen. We venture to affirm, that a very great majority of these facts are irreconcilable to the theory. The way in which circular arches commonly fail, is by the sinking of the crown and the rising of the flanks. It will be found by calculation, that in most of the cases it ought to have been just the contrary. But the clearest proof is, that arches very rarely fail where their load differs most remarkably from that which this theory allows. Semicircular arches have stood the power of ages, as may be seen in the bridges of ancient Rome, and in the numerous arcades which the ancient inhabitants have erected. Now, all arches which spring perpendicularly from the horizontal line require, by this theory, a load of infinite height; and even to a considerable distance from the springing of the arch, the load necessary for the theoretical equilibrium is many times greater than what is ever laid on those parts; yet a failure in the immediate neighbourhood of the spring of an arch is a most rare phenomenon, if it ever was observed. Here is a most remarkable deviation from the theory; for, as is already observed, the load is frequently not the fourth part of what the theory requires.

28. Many other facts might be adduced which show great deviation from the legitimate results of the theory. We hope to be excused, therefore, by the mathematicians for doubting of the justness of this theory. We do not think it erroneous, but defective, leaving out circumstances which we apprehend to be of great importance; and we imagine that the defects of the theory have arisen from the very anxiety of the mechanicians to make it perfect. The arch-stones are supposed to be perfectly smooth or polished, and not to be connected by any cement, and therefore to sustain each other merely by the equilibrium of their vertical pressure. The theory insures this equilibrium, and this only, leaving unnoticed any other causes of mutual action.

The authors who have written on the subject say expressly that an arch which thus sustains itself must be stronger than another which would not; because when, in imagination, we suppose both to acquire connection by cement, the first preserves the influence of this connection unimpaired; whereas in the other, part of the cohesion is wasted in counteracting the tendency of some parts to break off from the rest by their want of equilibrium. This is a very specious argument, and would be just, if the forces which are mutually exerted between the parts of the arch in its settled state were merely vertical pressures, or, where different, were inconsiderable in comparison with those which are really attended to in the construction.

But this is by no means the case. The forms which the uses for which arches are erected oblige us to adopt, and the loads laid on the different points of the arch, frequently deviate considerably from what are necessary for the equilibrium of vertical pressures. The varying load on a bridge, when a great waggon passes along it, sometimes bears a very sensible proportion to the weight of that point of the arch on which it rests. It is even very doubtful whether the pressures which are occasioned by the weight of the stuff employed for filling up the flanks really act in a vertical direction, and in the proportion which is supposed. We are pretty certain that this is not the case with sand, gravel, fat mould, and many substances in very general use for this purpose. When this is the case, the pressures sustained by the different parts of the arch are often very inconsistent with the theory; a part of the arch is overloaded and tends to fall in, but is prevented by the cement. This part of the arch, therefore, acts on the remoter parts by the intervention of the parts between, employing those intermediate parts as a kind of levers to break the arch in a remote part, just as a lintel would be broken. We apprehend that a mathematician would be puzzled how to explain the stability of an arch cut out of a solid and uniform mass of rock. His theory considers the mutual thrusts of the arch-stones as in the direction of the tangents to the arch. Why so? Because he supposes that all his polished joints are perpendicular to those tangents. But in the present case he has no existing joints; and there seems to be nothing to direct his imagination in the assumption of joints, which, however, are absolutely necessary for employing his theory, because, without a supposition of this kind, there seems no conceiving any mutual abutment of the arch-stones. Ask a common but intelligent mason, what notion he forms of such an arch? We apprehend that he will consider it as no arch, but as a lintel, which may be broken like a wooden lintel, and which resists entirely by its cohesion. He will not readily conceive that, by cutting the under side of a stone lintel into an arched form, and thus taking away more than half of its substance, he has changed its nature of a lintel, or given it any additional strength. Nor would there be any change made in the way in which such a mass of stone would resist being broken down, if nothing were done but forming the under side into an arch. If the lintel be so laid on the piers that it can be broken without its parts pushing the piers aside (which will be the case if it lies on the piers with horizontal joints), it will break like any other lintel; but if the joints are directed downwards, and converging to a point within the arch, the broken stone (suppose it broken at the crown by an overload in that part) cannot be pressed down without forcing the piers outwards. Now, in this mode of acting, the mind cannot trace any thing of the statical equilibrium that we have proceeded on in the foregoing theory. The two parts of the broken lintel seem to push the piers aside in the same manner that two rafters push outwards the walls of a house when their feet are not held together by a tie-beam. If the piers cannot be pushed aside (as when the arch abuts on two solid rocks), nothing can press down the crown which does not crush the stone.

This conclusion will be strictly true if the arch is of such a form that a straight line drawn from the crown to the pier lies wholly within the solid masonry. Thus, if the vault consist of two straight stones, as in Plate XLVIII. fig. 1, or if it consist of several stones, as in Plate XLIX. fig. 7, disposed in two straight lines, no weight laid on the crown can destroy it in any other way than by crushing it to powder.

29. But when straight lines cannot be drawn from the overloaded part to the firm abutments through the solid masonry, and when the cohesion of the parts is not able to withstand the transverse strains, we must call the principles of equilibrium to our aid; and, in order to employ them with safety, we must consider how they are modified by the excitement of the cohering forces.

The cohesion of the stones with each other by cement or otherwise has in almost every situation a bad effect. It enables an overload at the crown to break the arch near the haunches, causing those parts to rise, and then to spread outwards, just as a Mansarde or Kirb roof would do if the truss-beam which connects the heads of the lower rafters were sawn through. This can be prevented

Arch. only by loading that part more than is requisite for equilibrium. It would be prudent to do this to a certain degree, because it is by this cohesion that the crown always becomes the weakest part of the arch, and suffers more by any occasional load.

We expect that it will be said in answer to all this, that the cohesion given by the strongest cement that we can employ, nay the cohesion of the stone itself, is a mere nothing in comparison with the enormous thrusts that are in a state of continual exertion in the different parts of an arch. This is very true; but there is another force which produces the same effect, and which increases nearly in the proportion that those thrusts increase, because it arises from them. This is the friction of the stones on each other. In dry freestone this friction considerably exceeds one half of the mutual pressure. The reflecting reader will see that this produces the same effect, in the case under consideration, that cohesion would do; for while the arch is in the act of failing, the mutual pressure of the arch-stones is acting with full force, and thus produces a friction more than adequate to all the effects we have been speaking of.

Process of the breaking of an arch.

30. When these circumstances are considered, we imagine that it will appear that an arch, when exposed to a great overload on the crown (or indeed on any part), divides of itself into a number of parts, each of which contains as many arch-stones as can be pierced (so to speak) by one straight line, and that it may then be considered as nearly in the same situation with a polygonal arch of long stones abutting on each other like so many beams in a Norman roof, but without their braces and ties. It tends to break at all those angles; and it is not sufficiently resisted there, because the materials with which the flanks are filled up have so little cohesion, that the angle feels no load except what is immediately above it; whereas it should be immediately loaded with all the weight which is diffused over the adjoining side of the polygon. This will be the case, even though the curvilinear arch be perfectly equilibrated. We recollect some circumstances in the failure of a considerable arch, which may be worth mentioning. It had been built of an exceedingly soft and friable stone, and the arch-stones were too short. About a fortnight before it fell, chips were observed to be dropping off from the joints of the arch-stones, about ten feet on each side of the middle, and also from another place on one side of the arch, about twenty feet from its middle. The masons in the neighbourhood prognosticated its speedy downfall, and said that it would separate in those places where the chips were breaking off. At length it fell; but it first split in the middle, and about fifteen or sixteen feet on each side, and also at the very springing of the arch. Immediately before the fall a shivering or crackling noise was heard, and a great many chips dropped down from the middle, between the two places from whence they had dropped a fortnight before. The joints opened above at those new places above two inches, and in the middle of the arch the joints opened below, and in about five minutes after this the whole came down. Even this movement was plainly distinguishable into two parts. The crown sunk a little, and the haunches rose very sensibly, and in this state it hung for about half a minute. The arch-stones of the crown were hanging by their upper corners: when these splintered off, the whole fell down.

We apprehend that the procedure of nature was somewhat in this manner. Straight lines can be drawn within the arch-stones from A (Plate XLIX. fig. 8) to B and D, and from these points to C and E. Each of the portions ED, DA, AB, BC, resist as if they were of one stone, composing a polygonal vault EDABC. When this is overloaded at A, A can descend in no other way than by pushing the angles B and D outwards, causing the portions BC, DE, to turn round C and E. This motion must raise the points B and D, and cause the arch-stones to press on each other at their *inner* joints *b* and *d*. This produced the copious splintering at those joints immediately preceding the total downfall. The splintering which happened a fortnight before arose from this circumstance, that the lines AB and AD, along which the pressure of the overload was propagated, were tangents to the soffit of the arch in the points F, H, and G, and therefore the strain lay all on those corners of the arch-stones, and splintered a little from off them till the whole took a firmer bed. The subsequent phenomena are evident consequences of this distribution and modification of pressure, and can hardly be explained in any other way, at least not on the theoretical principles already set forth; for in this bridge the loads at B and D were very considerably greater than what the equilibrium required; and we think that the first observed splintering at H, F, and G, was most instructive, showing that there was an extraordinary pressure at the inner joints in those places, which cannot be explained by the usual theory.

Not satisfied with this single observation after this way of explaining it occurred to us, and not being able to find any similar fact on record, the writer of this article got some small models of arches executed in chalk, and subjected them to many trials, in hopes of collecting some general laws of the internal workings of arches which finally produce their downfall. He had the pleasure of observing the above-mentioned circumstances take place very regularly and uniformly when he overloaded the models at A. The arch always broke at some place B considerably beyond another point F, where the first chipping had been observed. This is a method of trial that deserves the attention both of the speculatist and the practitioner.

If these reflections are any thing like a just account of the procedure of nature in the failure of an arch, it is evident that the ingenious mathematical theory of equilibrated arches is of little value to the engineer. We ventured to say as much already, and we rested a good deal on the authority of Sir Christopher Wren. He was a good mathematician, and delighted in the application of this science to the arts. He was a celebrated architect, and his reports on the various works committed to his charge show that he was in the continued habit of making this application. Several specimens remain of his own methods of applying them. The roof of the theatre of Oxford, the roof of the cupola of St Paul's, and in particular the mould on which he turned the inner dome of that cathedral, are proofs of his having studied this theory most attentively. He flourished at the very time that it occupied the attention of the greatest mechanicians of Europe; but there is nothing to be found among his papers which shows that he had paid much regard to it. On the contrary, when he has occasion to deliver his opinion for the instruction of others, and to explain to the dean and chapter of Westminster his operations in repairing that collegiate church, this great architect considers an arch just as a sensible and sagacious mason would do, and very much in the way that we have just now been treating it. (See *Account of the Family of Wren*, p. 356.) Supported therefore by such authority, we would recommend this way of considering an arch to the study of the mathematician; and we would desire the experienced mason to think of the most efficacious methods for resisting this tendency of arches to rise in the flanks. Unfortunately there seems to be no precise principle to point out the place where this tendency is most remarkable.

31. We are therefore highly pleased with the ingenious

Arch.

contrivance of Mr Mylne, the architect of Blackfriars Bridge in London, by which he determines this point with precision, by making it impossible for the overloaded arch to spring in any other place. Having thus confined the failure to a particular spot, he with equal art opposes a resistance which he believes to be sufficient; and the present condition of that noble bridge, which does not in any place show the smallest change of shape, proves that he was not mistaken. Looking on this work as the first, or at least the second, specimen of masonic ingenuity that is to be seen in the world, we imagine that our readers will be pleased with a particular account of its most remarkable circumstances.

Construction of Blackfriars Bridge. Pl. XLIX.

The span *k a* (fig. 1) of the middle arch is 100 feet, and its height OV is 40, and the thickness KV of the crown is six feet seven inches. Its form is nearly elliptical; the part AVZ being an arch of a circle whose centre is C, and radius 56 feet, and the two lateral portions A *k* B and Z *a* E being arches described with a radius of 35 feet nearly. The thickness of the pier at *a b* is 19 feet. The thickness of the arch increases from the crown V to Y, where it is eight or nine feet. All the arch-stones have their joints directed to the centres of their curvature. The joints are all joggled, having a cubic foot of hard stone let half-way into each. By this contrivance the joints cannot slide, nor can any weight laid on the crown ever break the arch in that part if the piers do not yield; for a straight line from the middle of KV to the middle of the joint YI is contained within the solid masonry, and does not even come near the inner joints of the arch-stones; therefore the whole resists like one stone, and can be only broken by crushing it. The joint at Z is very nearly perpendicular to a line ZF drawn to the outer edge of the foundation of the pier. By this it was intended to take off all tendency of the pressure on the joint *d* Z to overset the pier; for if we suppose, according to the theory of equilibration, that this pressure is necessarily exerted perpendicularly to the joint, its direction passes through the fulcrum at F, round which it is thought that the pier must turn in the act of oversetting. This precaution was adopted in order to make the arch quite independent of the adjoining arches; so that although any of them should fall, this arch should run no risk.

Still farther to secure the independence of the arch, the following construction was practised to unite it into one mass, which should rise all together. All below the line *a b* is built of large blocks of Portland stone, dovetailed with sound oak. Four places in each course are interrupted by equal blocks of a hard stone called *Kentish rag*, sunk half-way in each course. These act as joggles, breaking the courses, and preventing them from sliding laterally.

The portion *a* Y of the arch is joggled like the upper part. The interior part is filled up with large blocks of Kentish rag, forming a kind of coursed rubble-work, the courses tending to the centres of the arch. The under corner of each arch-stone projects over the one below it. By this form it takes fast hold of the rubble-work behind it. Above this rubble there is constructed the inverted arch I *e* G of Portland stone.[1] This arch shares the pressure of the two adjoining arches, along with the arch-stones in Y *a* and in G *b*. Thus all tend together to compress and keep down the rubble-work in the heart of this part of the pier. This is a very useful precaution; for it often happens, that when the centres of the arches are struck before the piers are built up to their intended heights, the thrust of the arches squeezes the rubble-work horizontally, after the mortar has set, but before it has dried and acquired its utmost hardness. Its bond is broken by this motion, and it is squeezed up, and never acquires its former firmness. This is effectually prevented by the pressure exerted by the back of the inverted arch.

Above this counter-arch is another mass of coursed rubble, and all is covered by a horizontal course of large blocks of Portland stone, abutting against the back of the arch-stone ZI and its corresponding one in the adjoining arch. This course connects the feet of the two arches, preserves the rubble-work from too great compression, and protects it from soaking water. This last circumstance is important; for if the water which falls on the road-way is not carried off in pipes, it soaks through the gravel or other rubbish, rests on the mortar, and keeps it continually wet and soft. It cannot escape through the joints of good masonry, and therefore fills up this part like a funnel.

Supposing the adjoining arch fallen, and all tumbled off that is not withheld by its situation, there will still remain in the pier a mass of about 3500 tons. The weight of the portion VY is about 2000 tons. The directions of the thrusts VY and YF are such, that it would require a load of 4500 tons on VY to overturn the pier round F. This exceeds VY by 2500 tons—a weight incomparably greater than any that can ever be laid on it.

Such is the ingenious construction of Mr Mylne. It evidently proceeds on the principles recommended above—principles which had occurred to his experience and sagacious mind during the course of his extensive practice. We have seen attempts by other engineers to withstand the horizontal thrusts of the arch by means of counter-arches inserted in the same manner as here, but extending much farther over the main arch; but they did not appear to be well calculated for producing this effect. A counter-arch springing from any point between Y and V has no tendency to hinder that point from rising by the sinking of the crown; and such a counter-arch will not resist the precisely horizontal thrust so well as the straight course of Mr Mylne.

Origin of the Gothic arches.

32. The great incorporation of architects who built the cathedrals of Europe departed entirely from the styles of ancient Greece and Rome, and introduced another, in which arcades made the principal part. Not finding in every place quarries from which blocks could be raised in abundance of sufficient size for forming the far-projecting cornices of the Greek orders, they relinquished those proportions, and adopted a style of ornament which required no such projections; and having substituted arches for the horizontal architrave or lintel, they were now able to erect buildings of vast extent with spacious openings, and all this with very small pieces of stone. The form which had been adopted for a Christian temple occasioned many intersections of vaultings, and multiplied the arches exceedingly. Constant practice gave opportunities of giving every possible variety of these intersections, and taught the art of balancing arch against arch in every variety of situation. An art so multifarious, and so much out of the road of ordinary thought, could not but become an object of fond study to the architects most eminent for ingenuity and invention. Becoming thus the dupes of

[1] We know from good authority that the counter-arch here spoken of, although originally intended, was never executed, because it was not thought necessary. The notion was, however, excellent, and it has, we believe, been actually executed in the Strand Bridge. We rather think the joggling was also abandoned, and, as far as we can judge, was not likely to be of any use.

their own ingenuity, they were fond of displaying it even when not necessary. At last arches became their principal ornament, and a wall or ceiling was not thought dressed out as it should be till filled full of mock arches, crossing and abutting on each other in every direction. In this process in their ceilings they found that the projecting mouldings, which we now call the Gothic tracery, formed the chief supports of the roofs. The plane surfaces included between those ribs were commonly vaulted with very small stones, seldom exceeding six or eight inches in thickness. This tracery, therefore, was not a random ornament. Every rib had a position and direction that was not only proper, but even necessary. Habituated to this scientific arrangement of the mouldings, they did not deviate from it when they ornamented a smooth surface with mock arches; and in none of the highly ornamented *ancient* buildings will we find any false positions.

33. This is by no means the case in many of the modern imitations of Gothic architecture, even by our best architects. Ignorant of the directing principle, or not attending to it, in their stucco-work they please the unskilled eye with pretty radiated figures; but in these we frequently see such abutments of mouldings as would infallibly break the arches, if these mouldings were really performing their ancient office, and supporting a vaulting of considerable extent. Nay, this began even before the Gothic style was finally abandoned. Several instances are to be found in the highly enriched vaultings of New College and Christ Church in Oxford, in St George's Chapel at Windsor, and Henry VII.'s Chapel in Westminster.

We call the middle ages rude and barbarous; but there was surely much knowledge in those who could execute such magnificent and difficult works. The working drafts which were necessary for such varieties of oblique intersections must have required considerable skill, and would at present occupy many very expensive volumes of *Masons' Jewels*, *Carpenters' Manuals*, and the like. All this knowledge was kept a profound secret by the corporation, and on its breaking up we had all to learn again.

34. There is no appearance, however, that those architects had studied the theory of equilibrated arches. They had adopted an arch which was very strong, and permitted considerable irregularities of pressure—we mean the pointed arch. The very deep mouldings with which it was ornamented made the arch-stones very long in proportion to the span of the arch. But they had studied the mutual thrust of arches on each other with great care; and they contrived to make every invention for this purpose become an ornament, so that the eye *required* it as a necessary part of the building. Thus we frequently see small buildings having buttresses at the sides. These are necessary in a large vaulted building, for withstanding the outward thrust of the vaulting; but they are useless when we have a flat ceiling within. Pinnacles on the heads of the buttresses are now considered as ornaments, but originally they were put there to increase the weight of the buttress: even the great tower in the centre of a cathedral, which now constitutes its greatest ornament, is a load almost indispensably necessary, for enabling the four principal columns to withstand the combined thrust of the aisles, of the nave, and transepts. In short, the more closely we examine the ornaments of this architecture, the more shall we perceive that they are essential parts, or derived from them by imitation; and the more we consider the whole style of it, the more clearly do we see that it is all deduced from the relish for arcades, indulged in the extreme, and pushed to the limit of possibility of execution.

Dome or Cupola.

35. There is another species of arch which must not be overlooked, namely, the DOME or CUPOLA, with all its varieties, which include even the pyramidal steeple or spire.

It is evident that the erection of a dome is also a scientific art, proceeding on the principles of equilibration, and that these principles admit and require the same or similar modifications, in consequence of the cohesion and friction of the materials. At first sight, too, a dome appears a more difficult piece of work than a plain arch; but when we observe potters' kilns, and glasshouse domes, and cones of vast extent, erected by ordinary bricklayers, and with materials vastly inferior in size to what can be employed in common arches of equal extent, we must conclude that the circumstance of curvature in the horizontal direction, or the abutment of a circular base, gives some assistance to the artist. Of this we have complete demonstration in the case of the cone. We know that a vaulting in the form of a pent roof could not be executed to any considerable extent, and would be extremely hazardous, even in the smallest dimensions; while a cone of the greatest magnitude can be raised with very small stones, provided only that we prevent the bottom from flying out, by a hoop, or any similar contrivance.

36. When we think a little of the matter, we see plainly, that if the horizontal section be perfectly round, and the joints be all directed to the axis, they all equally endeavour to slide inwards, while no reason can be offered why any individual stone should prevail. They are all wedges, and operate only as wedges. When we consider any single course, therefore, we see that it cannot fall in, even though it may be part of a curve which cannot stand as a common arch; nay, we see that a dome may be constructed having the convexity of the curve, by the revolution of which it is formed, turned towards the axis, so that the outline is concave. We shall afterwards find that this is a stronger dome by far than if the convexity were outwards, as in a common arch. We see also that a cone may be loaded on the top with the greatest weight, without the smallest danger of forcing it down, so long as the bottom course is firmly kept from bursting outwards. The stone lanthorn on the top of St Paul's cathedral in London weighs several hundred tons, and is carried by a brick cone of 18 inches thick, with perfect safety, as long as the bottom course is prevented from bursting outwards. The reason is evident: The pressure on the top is propagated along the cone in the direction of the slant side; and, so far from having any tendency to break it in any part, it tends rather to prevent its being broken by any irregular pressure from foreign causes.

Proper construction of octagonal pyramids.

37. For the same reasons the octagonal pyramids, which form the spires of Gothic architecture, are abundantly firm, although very thin. The sides of the spire of Salisbury cathedral are not eight inches thick after the octagon is fully formed. It is proper, however, to direct the joints to the axis of the pyramid, and to make the coursing joints perpendicular to the slant side, because the projecting mouldings which run along the angles are the abutments on which the whole panel depends. A considerable art is necessary for supporting those panels or sides of the octagon which spring from the angles of the square tower. This is done by beginning a very narrow pointed arch on the square tower at a great distance below the top; so that the legs of the arch being very long, a straight line may be drawn from the top of the keystone of the arch through the whole arch-stones of the legs. By this disposition the thrusts arising from the weight of these four panels are made to meet on the massive masonry in the middle of the sides of the tower, at a great

distance below the springing of the spire. This part, being loaded with the great mass of perpendicular wall, is fully able to withstand the horizontal thrust from the legs of those arches. In many spires these thrusts are still farther resisted by iron bars which cross the tower, and are hooked into pieces of brass firmly bedded in the masonry of the sides.

38. There is much nice balancing of this kind to be observed in the highly ornamented open spires; such as those of Brussels, Mecklin, Antwerp, &c. We have not many of this sort in Britain. In those of great magnitude, the judicious eye will discover, that parts, which a common spectator would consider as mere ornaments, are necessary for completing the balance of the whole. Tall pinnacles, nay even pillars carrying entablatures and pinnacles, are to be seen standing on the middle of the slender leg of an arch. On examination we find that this is necessary, to prevent the arch from springing upwards in that place by the pressure at the crown. The steeple of the cathedral of Mecklin was the most elaborate piece of architecture in this taste in the world, and was really a wonder; but it was not calculated to withstand a bombardment, which destroyed it in 1578.

Such frequent examples of irregular and whimsical buildings of this kind show that great liberties may be taken with the principle of equilibration without risk, if we take care to secure the base from being thrust outwards. This may always be done by hoops, which can be concealed in the masonry; whereas in common arches these ties would be visible, and would offend the eye.

39. It is now time to attend to the principle of equilibrium as it operates in a simple circular dome, and to determine the thickness of the vaulting when the curve is given, or the curve when the thickness is given. Therefore, let B b A (Plate XLIX. fig. 2) be the curve which produces the dome by revolving round the vertical axis AD. We shall suppose this curve to be drawn through the middle of all the arch-stones, and that the coursing or horizontal joints are everywhere perpendicular to the curve. We shall suppose (as is always the case) that the thickness KL, HI, &c. of the arch-stones is very small in comparison with the dimensions of the arch. If we consider any portion HAh of the dome, it is plain that it presses on the course, of which HL is an arch-stone, in a direction bC perpendicular to the joint HI, or in the direction of the next superior element βb of the curve. As we proceed downwards, course after course, we see plainly that this direction must change, because the weight of each course is superadded to that of the portion above it, to complete the pressure on the course below. Through B draw the vertical line BCG, meeting βb, produced in C. We may take bC to express the pressure of all that is above it, propagated in this direction to the joint KL. We may also suppose the weight of the course HL united in b, and acting on the vertical. Let it be represented by bF. If we form the parallelogram bFGC, the diagonal bG will represent the direction and intensity of the whole pressure on the joint KL. Thus it appears that this pressure is continually changing its direction, and that the line, which will always coincide with it, must be a curve concave downward. If this be precisely the curve of the dome, it will be an equilibrated vaulting; but so far from being the strongest form, it is the weakest, and it is the limit to an infinity of others, which are all stronger than it. This will appear evident, if we suppose that bG does not coincide with the curve AbB, but passes without it. As we suppose the arch-stones to be exceedingly thin from inside to outside, it is plain that this dome cannot stand, and that the weight of the upper part will press it down, and spring the vaulting outwards at the joint KL. But let us suppose, on the other hand, that bG falls within the curvilinear element bB. This evidently tends to push the arch-stone inward towards the axis, and would cause it to slide in, since the joints are supposed perfectly smooth and slipping. But since this takes place equally in every stone of this course, they must all abut on each other in the vertical joints, squeezing them firmly together. Therefore, resolving the thrust bG into two, one of which is perpendicular to the joint KL, and the other parallel to it, we see that this last thrust is withstood by the vertical joints all around, and there remains only the thrust in the direction of the curve. Such a dome must therefore be firmer than an equilibrated dome, and cannot be so easily broken by overloading the upper part. When the curve is concave upwards, as in the lower part of the figure, the line bC always falls below bB, and the point C below B. When the curve is concave downwards, as in the upper part of the figure, b'C' passes above, or without bB. The curvature may be so abrupt, that even b'G' shall pass without b'B', and the point G' is above B'. It is also evident that the force which thus binds the stones of a horizontal course together, by pushing them towards the axis, will be greater in flat domes than in those that are more convex; that it will be still greater in a cone, and greater still in a curve whose convexity is turned inwards, for in this last case the line bG will deviate most remarkably from the curve. Such a dome will stand (having polished joints) if the curve springs from the base with any elevation, however small; nay, since the friction of two pieces of stone is not less than half of their mutual pressure, such a dome will stand although the tangent to the curve at the bottom should be horizontal, provided that the horizontal thrust be double the weight of the dome, which may easily be the case if it do not rise high.

Stability of a dome depends on principles different from that of a common arch.

40. Thus we see that the stability of a dome depends on very different principles from that of a common arch, and is in general much greater. It differs also in another very important circumstance, viz. that it may be open in the middle; for the uppermost course, by tending equally in every part to slide in toward the axis, presses all together in the vertical joints, and acts on the next course like the keystone of a common arch. Therefore an arch of equilibration, which is the weakest of all, may be open in the middle, and carry at top another building, such as a lanthorn, if its weight do not exceed that of the circular segment of the dome that is omitted. A greater load than this would indeed break the dome, by causing it to spring up in some of the lower courses; but this load may be increased if the curve is flatter than the curve of equilibration: and any load whatever, which will not crush the stones to powder, may be set on a truncate cone, or on a dome formed by a curve that is convex toward the axis; provided always that the foundation be effectually prevented from flying out, either by a hoop, or by a sufficient mass of solid pier on which it is set.

41. We have mentioned the many failures which happened to the dome of St Sophia in Constantinople. We imagine that the thrust of the great dome, bending the eastern arch outwards as soon as the pier began to yield, destroyed the half-dome which was leaning on it, and thus almost in an instant took away the eastern abutment. We think that this might have been prevented without any change in the injudicious plan, if the dome had been hooped with iron, as was practised by Michael Angelo in the vastly more ponderous dome of St Peter's at Rome, and by Sir Christopher Wren in the cone and the inner dome of St Paul's at London. The weight of the latter considerably exceeds 3000 tons, and they occasion a horizontal thrust which is nearly half this quantity, the elevation of the cone being about 60°. This being distributed

Arch.

round the circumference, occasions a strain on the hoop $= \frac{7}{2 \times 22}$ of the thrust, or nearly 238 tons. A square inch of the worst iron, if well forged, will carry 24 tons with perfect safety; therefore a hoop of 7 inches broad and $1\frac{1}{2}$ inch thick will completely secure this circle from bursting outwards. It is, however, much more completely secured; for, besides a hoop at the base of very nearly these dimensions, there are hoops in different courses of the cone, which bind it into one mass, and cause it to press on the piers in a direction exactly vertical. The only thrusts which the piers sustain are those from the arches of the body of the church and the transepts. These are most judiciously directed to the entering angles of the building, and are there resisted with insuperable force by the whole lengths of the walls, and by four solid masses of masonry in the corners. Whoever considers with attention and judgment the plan of this cathedral, will see that the thrusts of these arches, and of the dome, are incomparably better balanced than in St Peter's church at Rome. But to return from this sort of digression.

Theory of the curves proper for domes.

42. We have seen that if b G, the thrust compounded of the thrust b C, exerted by all the courses above HILK, and of the force b F, or the weight of that course, be everywhere coincident with b B, the element of the curve, we shall have an equilibrated dome: if it falls within it, we have a dome which will bear a greater load; and if it falls without it, the dome will break at the joint. We must endeavour to get analytical expressions of these conditions. Therefore draw the ordinates $b\,\delta\,b''$, BDB'', C d C''. Let the tangents at b and b'' meet the axis in M, and make MO, MP, each equal to bc, and complete the parallelogram MONP, and draw OQ perpendicular to the axis, and produce b F, cutting the ordinates in E and e.[1] It is plain that MN is to MO as the weight of the arch HAb to the thrust b C which it exerts on the joint KL (this thrust being propagated through the course HILK); and that MQ, or its equal $b\,e$, or $\delta\,d$, may represent the weight of the half HA.

Let AD be called x, and DB be called y. Then $be = dx$, and $e\,\mathrm{C} = dy$ (because b C is in the direction of the element $\beta\, b$). It is also plain that if we make dy constant, BC is the second fluxion of x, or BC $= d^2x$, and be and bE may be considered as equal, and taken indiscriminately for dx. We have also $b\,\mathrm{C} = \sqrt{dx^2+dy^2}$. Let h be the depth or thickness HI of the arch-stones. Then $h\sqrt{dx^2+dy^2}$ will represent the trapezium HL; and since the circumference of each course increases in the proportion of the radius y, $hy\sqrt{dx^2+dy^2}$ will express the whole course. If $\int$ be taken to represent the sum or aggregate of the quantities annexed to it, the formula will be analogous to the fluent of a fluxion, and $\int hy\sqrt{dx^2+dy^2}$ will represent the whole mass, and also the weight of the vaulting, down to the joint HI. Therefore we have this proportion, $\int hy\sqrt{dx^2+dy^2} : hy\sqrt{dx^2+dy^2} := b\,e : b\,\mathrm{F}, = b\,e : \mathrm{CG}, = \delta\,d : \mathrm{CG}, = dx : \mathrm{CG}$. Therefore $\mathrm{CG} = \frac{hydx\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}}$.

If the curvature of the dome be precisely such as puts it in equilibrium, but without any mutual pressure in the vertical joints, this value of CG must be equal to CB or to d^2x, the point G coinciding with B. This condition will be expressed by the equation $\frac{hydx\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}} = d^2x$, or, more conveniently, by $\frac{hy\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}} = \frac{d^2x}{dx}$. But this form gives only a tottering equilibrium, independent of the friction of the joints and the cohesion of the cement. An equilibrium, accompanied by some firm stability, produced by the mutual pressure of the vertical joints, may be expressed by the formula $\frac{hy\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}} > \frac{d^2x}{dx}$, or by $\frac{hy\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}} = \frac{d^2x}{dx} + \frac{dt}{t}$, where t is some variable positive quantity, which increases when x increases. This last equation will also express the equilibrated dome, if t be a constant quantity, because in this case $\frac{dt}{t}$ is $= 0$.

Since a firm stability requires that $\frac{hydx\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}}$ shall be greater than d^2x, and CG must be greater than CB; hence we learn that figures of too great curvature, whose sides descend too rapidly, are improper. Also, since stability requires that we have $\frac{hydx\sqrt{dx^2+dy^2}}{d^2x}$ greater than $\int hy\sqrt{dx^2+dy^2}$, we learn that the upper part of the dome must not be made very heavy. This, by diminishing the proportion of bF to bC, diminishes the angle CbG, and may set the point G above B, which will infallibly spring the dome in that place. We see here also, that the algebraic analysis expresses that peculiarity of dome-vaulting, viz. that the weight of the upper part may even be suppressed.

The fluent of the equation $\frac{hy\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}} = \frac{d^2x}{dx} + \frac{dt}{t}$ is most easily found: it is $\mathrm{L}\int hy\sqrt{dx^2+dy^2} = \mathrm{L}dx + \mathrm{L}t$, where L is the hyperbolic logarithm of the quantity annexed to it. If we consider dy as constant, and correct the fluent so as to make it nothing at the vertex, it may be expressed thus, $\mathrm{L}\int hy\sqrt{dx^2+dy^2} - \mathrm{L}a = \mathrm{L}dx - \mathrm{L}dy + \mathrm{L}t$. This gives us $\mathrm{L}\frac{\int hy\sqrt{dx^2+dy^2}}{a} = \mathrm{L}\frac{dx}{dy}t$, and therefore $\frac{\int hy\sqrt{dx^2+dy^2}}{a} = t\frac{dx}{dy}$.

This last equation will easily give us the depth of vaulting, or thickness h of the arch, when the curve is given. For its fluxion is $\frac{hy\sqrt{dx^2+dy^2}}{a} = \frac{dtdx + td^2x}{dy}$, and $h = \frac{adtdx + atd^2x}{ydy\sqrt{dx^2+dy^2}}$, which is all expressed in known quantities; for we may put in place of t any power or function of x or of y, and thus convert the expression into another, which will be applicable to all sorts of curves.

Instead of the second member $\frac{d^2x}{dx} + \frac{dt}{t}$, we might employ $\frac{pd^2x}{dx}$, where p is some number greater than unity. This will evidently give a dome having stability, because the original formula $\frac{hydx\sqrt{dx^2+dy^2}}{\int hy\sqrt{dx^2+dy^2}}$ will then be greater than d^2x. This will give $h = \frac{pax^{p-1}d^2x}{ydy^p\sqrt{dx^2+dy^2}}$. Each of these forms has its advantages when applied to particular cases. Each of them also gives $h = \frac{ad^2x}{ydy\sqrt{dx^2+dy^2}}$ when the curvature is such as is in precise equilibrium.

[1] The letters e and d are wanting in the plate; e ought to be at the intersection of b E and C c'', and d at that of AD and C c''.

And, lastly, if h be constant, that is, if the vaulting be of uniform thickness, we obtain the form of the curve, because then the relation of d^2x to dx and to dy is given.

The chief use of this analysis is to discover what curves are improper for domes, or what portions of given curves may be employed with safety. Domes are generally built for ornament, and we see that there is great room for indulging our fancy in the choice. All curves which are concave outwards will give domes of great firmness: they are also beautiful. The Gothic dome, whose outline is an undulated curve, may be made abundantly firm, especially if the upper part be convex and the lower concave outwards.

The chief difficulty in the case of this analysis arises from the necessity of expressing the weight of the incumbent part, or $\int hy\sqrt{dx^2+dy^2}$. This requires the measurement of the conoidal surface, which, in most cases, can be had only by approximation by means of infinite series. We cannot expect that the generality of practical builders are familiar with this branch of mathematics, and therefore will not engage in it here; but content ourselves with giving such instances as can be understood by such as have that moderate mathematical knowledge which every man should possess who takes the name of engineer.

The surface of any circular portion of a sphere is very easily had, being equal to the circle described with a radius equal to the chord of half the arch. This radius is evidently $=\sqrt{dx^2+dy^2}$.

In order to discover what portion of a hemisphere may be employed (for it is evident that we cannot employ the whole) when the thickness of the vaulting is uniform, we may recur to the equation or formula $\frac{hydx\sqrt{dx^2+dy^2}}{d\dot{x}^2}$ $=\int hy\sqrt{dx^2+dy^2}$. Let a be the radius of the hemisphere. We have $dx=\frac{aydy}{\sqrt{a^2-y^2}}$, and $d^2x=\frac{a^2dy^2}{(a^2-y^2)^{\frac{3}{2}}}$. Substituting these values in the formula, we obtain the equation $y^2\sqrt{a^2-y^2}=\int\frac{a^2ydy}{\sqrt{a^2-y^2}}$. We easily obtain the fluent of the second member $=a^3-a^2\sqrt{a^2-y^2}$, and $y=a\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$. Therefore, if the radius of the sphere be 1, the half breadth of the dome must not exceed $\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$, or 0·786, and the height will be ·618. The arch from the vertex is about 51° 49′. Much more of the hemisphere cannot stand, even though aided by the cement, and by the friction of the coursing joints. This last circumstance, by giving connection to the upper parts, causes the whole to press more vertically on the course below, and thus diminishes the outward thrust; but it at the same time diminishes the mutual abutment of the vertical joints, which is a great cause of firmness in the vaulting. A Gothic dome, of which the upper part is a portion of a sphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very strong, and not ungraceful.

Dome of St Peter's at Rome.

43. But the public taste has long rejected this form, and seems rather to select more elevated domes than this portion of a sphere, because a dome, when seen from a small distance, always appears flatter than it really is. The dome of St Peter's is nearly an ellipsoid externally, of which the longer axis is perpendicular to the horizon. It is very ingeniously constructed. It springs from the base perpendicularly, and is very thick in this part. After rising about 50 feet, the vaulting separates into two thin vaultings, which gradually separate from each other. These two shells are connected together by thin partitions, which are very artificially dovetailed in both, and thus form a covering which is extremely stiff, while it is very light. Its great stiffness was necessary for enabling the crown of the dome to carry the elegant stone lanthorn with safety. It is a wonderful performance and has not its equal in the world; but it is an enormous load in comparison with the dome of St Paul's, and this even independent of the difference of size. If they were of equal dimensions, it would be at least five times as heavy, and is not so firm by its gravity; but as it is connected in every part by iron bars (lodged in the solid masonry, and well secured from the weather by having lead melted all around them), it bids fair to last for ages if the foundations do not fail.

If a circle be described round a centre, placed anywhere in the transverse axis AC (Plate XLVIII. fig. 11) of an ellipse, so as to touch the ellipse in the extremities B, b of an ordinate, it will touch it internally, and the circular arch B a b will be wholly within the elliptical arch BAb. Therefore, if an elliptical and a spherical vaulting spring from the same base, at the same angle with the horizon, the spherical vaulting will be within the elliptical, will be flatter and lighter, and therefore the weight of the next course below will bear a greater proportion to the thrust in the direction of the curve; therefore the spherical vaulting will have more stability. On the contrary, and for similar reasons, an oblate elliptical vaulting is preferable to a spherical vaulting springing with the same inclination to the horizon. (Fig. 13.)

Dimensions of the best form of a dome.

44. Persuaded that what has been said on the subject convinces the reader that a vaulting perfectly equilibrated throughout is by no means the best form, provided that the base is secured from separating, we think it unnecessary to give the investigation of that form, which has a considerable intricacy, and shall content ourselves with merely giving its dimensions. The thickness is supposed uniform. The numbers in the first column of the table express the portion of the axis counted from the vertex, and those of the second column are the lengths of the ordinates.

AD	DB	AD	DB	AD	DB
0,4	100	610,4	1080	2990	1560
3,4	200	744	1140	3442	1600
11,4	300	904	1200	3972	1640
26,6	400	1100	1260	4432	1670
52,4	500	1336	1320	4952	1700
91,4	600	1522	1360	5336	1720
146,8	700	1738	1400	5756	1740
223,4	800	1984	1440	6214	1760
326,6	900	2270	1480	6714	1780
465,4	1000	2602	1520	7260	1800

The curve delineated in fig. 15 is formed according to these dimensions, and appears destitute of gracefulness, because its curvature changes abruptly at a little distance from the vertex, so that it has some appearance of being made up of different curves pieced together. But if the middle be occupied by a lanthorn of equal or of smaller weight, this defect will cease, and the whole will be elegant, nearly resembling the exterior dome of St Paul's in London.

Advantages of dome-vaulting.

45. It is not a small advantage of dome-vaulting, that it is lighter than any that can cover the same area. If, moreover, it be spherical, it will admit considerable varieties of figure by combining different spheres. Thus, a dome may begin from its base as a portion of a large hemisphere, and may be broken off at any horizontal

course, and then a similar or a greater portion of a smaller sphere may spring from this course as a base. It also bears being intersected by cylindrical vaultings in every direction, and the intersections are exact circles, and always have a pleasing effect. It also springs most gracefully from the heads of small piers, or from the corners of rooms of any polygonal shape; and the arches formed by its intersections with the walls are always circular and graceful, forming very handsome spandrels in every position. For these reasons Sir Christopher Wren employed it in all his vaultings, and he has exhibited many beautiful varieties in the transepts and the aisles of St Paul's, which are highly worthy of the observation of architects. Nothing can be more graceful than the vaultings at the ends of the north and south transepts, especially as furnished off in the fine inside view published by Gwynn and Wale.

Effects of cement and friction in dome-vaulting.

46. The connection of the parts arising from cement and from friction has a great effect on dome-vaulting. In the same way as in common arches and cylindrical vaulting, it enables an overload on one place to break the dome in a distant place. But the resistance to this effect is much greater in dome-vaulting, because it operates all round the overloaded part. Hence it happens that domes are much less shattered by partial violence, such as the falling of a bomb or the like. Large holes may be broken in them without much affecting the rest; but, on the other hand, it greatly diminishes the strength which should be derived from the mutual pressure in the vertical joints. Friction prevents the sliding in of the arch-stones, which produces this mutual pressure in the vertical joints, except in the very highest courses, and even there it greatly diminishes it. These causes make a great change in the form which gives the greatest strength; and as their laws of action are as yet but very imperfectly understood, it is perhaps impossible, in the present state of our knowledge, to determine this form with tolerable precision. We see plainly, however, that it allows a greater deviation from the best form than the other kind of vaulting, and domes may be made to rise perpendicular to the horizon at the base, although of no great thickness; a thing which must not be attempted in a plain arch. The immense addition of strength which may be derived from hooping largely compensates for all defects; and there are hardly any bounds to the extent to which a very thin dome-vaulting may be carried when it is hooped or framed in the direction of the horizontal courses. The roof of the Halle du Bled at Paris is but a foot thick, and its diameter is more than 200, yet it appears to have abundant strength. It is, on the whole, a noble specimen of architecture.

The iron bridge at Sunderland described.

47. We must not conclude this article without taking notice of that magnificent and elegant arch erected in cast iron at Wearmouth, near Sunderland, in the county of Durham. The inventor and architect was Rowland Burdon, Esq.

This arch (of which a view is given at the article BRIDGE) is a segment of a circle whose diameter is about 444 feet. The span or chord of the arch is 236 feet, and its versed sine or spring is 34 feet. It springs at the elevation of 60 feet from the surface of the river at low water, so that vessels of 200 or perhaps 300 tons burden may pass under it in the middle of the stream, and even 50 feet on each side of it.

The sweep of the arch consists of a series of frames of cast iron, which abut on each other, in the same manner as the voussoirs of a stone arch. One of these frames or blocks (as we shall call them in future) is represented in Plate XLIX. fig. 3, as seen in front. It is cast in one piece, and consists of three pieces or arms BC, BC, BC, the middle one of which is two feet long, the upper being somewhat more, and the lower somewhat less, because their extremities are bounded by the radius drawn from the centre of the arch. These arms are four inches square, and are connected by other pieces KL, of such length that the whole length of the block is five feet in the direction of the radius. Each arm has a flat groove on each side, which is expressed by the darker shading, three inches broad and three fourths of an inch deep. A section of this block, through the middle of KL, is represented by the light-shaded part BBB, in which the grooves are more distinctly perceived. These grooves are intended for receiving flat bars of malleable iron, which are employed for connecting the different blocks with each other. Fig. 4 represents two blocks united in this manner. For this purpose each arm has two square bolt-holes. The ends of the arms being nicely trimmed off, so that the three ends abut equally close on the ends of the next block; and the bars of hammered iron being also nicely fitted to their grooves, so as to fill them completely, and have their bolt-holes exactly corresponding to those in the blocks; they are put together in such a manner that the joints or meetings of the malleable bars may fall on the middle between the bolt-holes in the arms. Flat-headed bolts of wrought iron are then put through, and keys or forelocks are driven through the bolt-tails, and thus all is firmly wedged together, binding each arm between two bars of wrought iron. These bars are of such length as to connect several blocks.

In this manner a series of about 125 blocks are joined together, so as to form the precise curve that is intended. This series may be called a rib, and it stands in a vertical plane. The arch consists of six of these ribs, distant from each other five feet. These ribs are connected together so as to form an arch of 32 feet in breadth, in the following manner.

Fig. 5 represents one of the bridles or cross pieces which connect the different ribs, as it appears when viewed from below. It is a hollow pipe of cast iron four inches in diameter, and has at each end two projecting shoulders, pierced with a bolt-hole near their extremities, so that the distance between the bolt-holes in the shoulders of one end is equal to the distance between the holes in the arms of the blocks, or the holes in the wrought iron bars. In the middle of the upper and of the under side of each end may be observed a square prominence, more lightly shaded than the rest. These projections also advance a little beyond the flat of the shoulders, forming between them a shallow notch about an inch deep, which receives the iron of the arms, where they abut on each other, and thus give an additional firmness to the joint. The manner in which the arms are thus grasped by these notches in the bridles is more distinctly seen in fig. 4, at the letter H, in the middle of the upper rail.

The rib having been all trimmed and put together, so as to form the exact curve, the bolts are all taken out, and the horizontal bridles are then set on in their places, and the bolts are again put in and made fast by the forelocks. The bolts now pass through the shoulders of the bridles, through the wrought iron bars, and through the cast iron arm that is between them, and the forelocks bind all fast together. The manner in which this connection is completed is distinctly seen in fig. 4, which shows in perspective a double block in front, and a single block behind it. The abutting joints of the two front blocks are at the letters E, E, E; the holes in the shoulders of the horizontal cross pieces are at H.

48. This construction is beautifully simple, and very judicious. A vast addition of strength and of stiffness is procured by lodging the wrought iron bars in grooves

formed in the cast iron rails; and for this purpose it is of great importance to make the wrought iron bars fill the grooves completely, and even to be so tight as to require the force of the forelocks to draw them home to the bottom of the grooves. There can be no doubt but that this arch is able to withstand an enormous pressure, as long as the abutments from which it springs do not yield. Of this there is hardly any risk, because they are masses of rock, faced with about four or five yards (in some places only) of solid block masonry. The mutual thrusts of the frames are all in the direction of the rails, so that no part bears any transverse strain. We can hardly conceive any force that can overcome the strength of those arms by pressure or crushing them. The manner in which the frames are connected into one rib effectually secures the abutting joints from slipping; and the accuracy with which the whole can be executed secures us against any warping or deviation of a rib from the vertical plane.

But when we consider the prodigious span of this arch, and reflect that it is only five feet thick, it should seem that the most perfect equilibration is indispensably necessary. It is but like a film, and must be so supple, that an overload on any part must have a great tendency to bend it, and to cause it to rise in a distant part; and this effect is increased by the very firmness with which the whole sticks together. The overloaded part acts on a distant part, tending to break it with all the energy of a long lever. This can be prevented only by means of the stiffness of the distant part. It is very true, the arch cannot break in the extrados except by tearing asunder the wrought iron bars which connect the blocks along the upper rail, and each of these requires more than a hundred tons to tear it asunder; yet an overload of five tons on any rib at its middle will produce this strain at twenty feet from the sides, supposing the sides held firm in their position. It were desirable, therefore, that something were done to stiffen the arch at the sides, by the manner of filling up the spandrels or space between the arch and the road-way. This is filled up in a manner that is extremely light and pleasing to the eye, namely, by large cast iron circles, which touch the extrados of the arch and touch the road-way. The road-way rests on them as on so many hoops, while they rest on the back of the arch, and also touch each other laterally. We cannot think that this contributes to the strength of the arch; for these hoops will be easily compressed at the points of contact, and, changing their shape, will oppose very little resistance. We think that this part of the arch might have been greatly stiffened and strengthened by connecting it with the road-way by trussed frames, in the same way that a judicious carpenter would have framed a roof. If a strong cast iron pillar had been made to rest on the arch at about 20 feet from the impost, and been placed in the direction of a radius, the top of this pillar might have been connected by a diagonal bar of wrought iron with the impost of the arch, and with the crown of the arch by another string or bar of the same materials. These two ties would cause the radial pillar to press strongly on the back of the arch, and they must be torn asunder before it could bend in that place in the smallest degree. Supposing them of the same dimensions as the bars in the arms, their position would give them near ten times the force for resisting the strain produced by an overload on the crown.

This beautiful arch contains only 260 tons of iron, of which about 55 are wrought iron. The superstructure is of wood, planked over a top. This floor is covered with a coating of chalk and tar, on which are laid the materials for the carriage road, consisting of marl, limestone, and gravel, with foot-ways of flag-stones at the sides. The weight of the whole did not exceed 1000 tons, whereas the lightest stone arch which could have been erected would have weighed 15,000. It was turned on a very light but stiff scaffolding, most judiciously constructed for the preservation of its form, and for allowing an uninterrupted passage for the numerous ships and small craft which frequent the busy harbour of Sunderland. The mode of framing the arch was so simple and easy that it was put up in ten days, without an accident; and when all was finished, and the scaffolding removed, the arch did not sensibly change its form. The whole work was executed in three years, and cost about L.26,000.

Appendix.

49. The excellence of the preceding article, written by the late Dr John Robison, Professor of Natural Philosophy in the University of Edinburgh, for the Supplement to the third edition of this work, may be inferred from the fact, that almost every later writer on mechanics has spoken of it with approbation, and borrowed more or less from it. (See Gregory's *Mechanics*, book i. chap. 6; Hutton's *Tracts*, vol. i., Bridges; Whewell's *Mechanics*, art. 72, &c.) There is however one part of the article, viz. the purely mathematical part, which must have been quite unintelligible as it originally appeared, because of its numerous typographical errors. These are here corrected, we believe for the first time. Even with this advantage, we fear it has rather a forbidding aspect to the student of modern mathematics, because of the very complicated diagram (see Plate XLVIII. fig. 12) from which the differential equation of the equilibrated arch has been deduced. We shall therefore, as an appendix, treat of the equilibrated polygon and equilibrated arch upon the general principles of statics, and employ in this investigation only the most simple geometrical figures. The theory of the equilibrated arch cannot be delivered without employing the principles of the differential and integral calculus; but we shall endeavour to pass from the finite equation of the equilibrated polygon to the differential equation of the arch by the shortest and most direct road.

Equilibrated Polygon.

50. In Plate XLIX. fig. 9, let ABCDED′C′B′A′ be a polygon formed by beams or rods AB, BC, CD, DE, &c. of any length, movable about the points B, C, D, E, &c. as joints, and forming an equilibrium in a vertical plane by the mutual thrusts at the joints and by the weight of the beams, the extreme sides of the polygon being supposed supported or attached to fixed points. Let AB, BC, CD, be any three consecutive sides of the polygon: produce AB, DC, the extreme sides, until they meet in H. The beam BC is kept in its position by the thrusts of the adjoining beams AB, CD, in the directions BH, CH, and its own weight, which is equivalent to pressures or loads on the joints B, C, acting in a vertical direction. Let G be the point in BC, which is the centre of gravity of weights proportional to loads at B and C. By the principles of statics, the directions of these forces must pass through the same point; therefore G must be in a vertical line passing through H.

51. Draw BL, CK, perpendicular to the vertical HG. Let φ, φ', φ'', denote the angles which the lines AB, BC, CD, in their order, make with any horizontal line in the plane of the polygon; then

$\varphi =$ angle HBL, $\varphi' =$ GBL $=$ GCK, $\varphi'' =$ HCK:

also let w denote the load on the joint B, and w' the load on the joint C.

By the nature of the centre of gravity,

$$w : w' = CG : BG = CK : BL,$$

therefore $w : w' = \frac{1}{BL} : \frac{1}{CK} = \frac{HG}{BL} : \frac{HG}{CK}$:

$$\text{Now } \frac{HG}{BL} = \frac{HL}{BL} - \frac{GL}{BL} = \tan.\ \varphi - \tan\ \varphi'$$

$$\text{and } \frac{HG}{CK} = \frac{GK}{CK} - \frac{HK}{CK} = \tan.\ \varphi' - \tan.\ \varphi'';$$

hence it appears that

$$w : w' = \tan.\ \varphi - \tan.\ \varphi' : \tan.\ \varphi' - \tan.\ \varphi''.$$

If w'' denote the load on the next joint D, and φ''' the angle which the line DE makes with the horizontal plane, it will appear in the same way that

$$w' : w'' = \tan.\ \varphi' - \tan.\ \varphi'' : \tan.\ \varphi'' - \tan.\ \varphi''',$$

and so on throughout the whole polygon: whence we have this important proposition:

The vertical pressures on any two joints of the polygon, whether adjoining or remote, are to one another as the differences of the tangents of the angles which the sides about the joints make with the plane of the horizon.

52. From this proposition we may infer, that if φ, φ' denote the angles which any two adjoining sides of the polygon make with the horizontal plane, and w the load on the joint at their intersection, then,

$$w = C\ (\tan.\ \varphi - \tan.\ \varphi') \ldots\ldots\ldots\ldots (A);$$

and in this formula, C denotes some constant quantity, which is the same for all the angles of the polygon. This is the general equation of the equilibrated polygon; and it shows that the loads at the joints depend entirely on the angles which the beams make with the horizontal plane, and are independent of the lengths of the beams themselves.

Equilibrated Arch.

53. We shall next investigate the differential equation of an equilibrated arch, deducing it from the finite equation of the equilibrated polygon.

Let us suppose an equilibrated polygon of a very great number of sides (fig. 10), and that a curve ABC passes through all the joints: the sides of the polygon will then be chords in the curve; and as the number of these may be conceived to be greater than any assigned number, and each shorter than any given line, they may be regarded as elements of the curve, and as constituting it.

54. Let us suppose the curve ABC formed in this manner to be the intrados of an arch of a bridge, and that the extrados is the line MDN, which may be curved or straight. Let AC be the *span*, or greatest horizontal width of the arch, and BH, which bisects AC at right angles, its *rise* or height; also let BD be the thickness of the arch of the crown: draw a straight line EDF perpendicular to DH, and draw AE, CF perpendicular to EF.

Let Pp be any indefinitely small part of the intrados ABC. Draw PRQ perpendicular to the horizontal line EF, meeting the extrados in R, and rp parallel to RP; also draw PK perpendicular to DH, meeting rp in q, and PT touching the intrados in p; and, referring the two curves to the same axes DE, let us put

$x =$ DQ the common abscissa,
$y =$ PQ the ordinate of the intrados,
$v =$ RQ the ordinate of the extrados,
$\varphi =$ angle TPK made by the tangent and horizontal line PK,
$c =$ DB the given value of y at the crown,
$c' =$ AE the given value of y at either haunch.

Then, because Pp is a differential of the arc BP, we have P$q = dx$, and $pq = dy$.

55. The load on the arc BP is the gravitating matter between it and DR, the arc of the extrados immediately over it. This is expressed by the area BDRP; therefore the load on Pp, the differential of the arc, is $(y - v)dx$, the differential of that area.

We have put φ to denote the angle which a tangent at P makes with any horizontal line; similarly, let φ' denote the angle which a line touching the curve at p makes with a horizontal line. If now the curve be considered as a polygon of an infinite number of infinitely short sides, and the lines which touch the curve at P and p as the prolongations of two adjoining sides, then, by formula (A), sect. 52, the vertical pressure at their intersection will be C (tan. φ — tan. φ'). But these infinitely short touching lines may be regarded as forming Pp, the differential of the curve, the load on which we have found to be $(y - v)dx$; and, moreover, $\tan.\ \varphi - \tan.\ \varphi' = d(\tan.\ \varphi)$, the differential of the trigonometrical tangent of φ; therefore, the relation between the intrados and extrados will be expressed by this equation,

$$C\, d(\tan.\ \varphi) = (y - v)dx.$$

Now in all curves, $\tan.\ \varphi = \frac{dy}{dx}$, and making dx constant, $d(\tan.\ \varphi) = \frac{d^2y}{dx}$, let us, to make the members of the equation homogeneous, put c^2 instead of C, which is always positive, and the above equation becomes

$$c^2 \frac{d^2y}{dx} = (y - v)dx;$$

and hence

$$\frac{d^2y}{dx^2} - \frac{y}{c^2} = -\frac{v}{c^2} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (B).$$

This differential equation, which is of the second order, and *linear*, or of the first degree, comprehends in it the whole theory of the equilibrated arch. We may now deduce from it the resolution of two problems.

Prob. 1. Having given the form of the intrados ABC, to find that of the extrados.

Prob. 2. Having given the nature of the extrados, to determine the intrados.

56. The first problem is easy, and may be resolved by the differential calculus.

Ex. Let the intrados ABC be a segment of a circle whose centre is O. Draw PO to the centre. Let $\varphi =$ angle POB, and $a =$ PO the radius of the circle; then,

$$x = DQ = PK = a \sin.\ \varphi,$$
$$y = PQ = BD + BK = c' + a\ (1 - \cos.\ \varphi),$$
$$dx = a \cos.\ \varphi\, d\varphi, \qquad dy = a \sin.\ \varphi d\varphi,$$
$$\frac{dy}{dx} = \frac{\sin.\ \varphi}{\cos.\ \varphi} = \tan.\ \varphi; \quad \frac{d^2y}{dx} = \frac{d\varphi}{\cos.^2\varphi},$$
$$\frac{d^2y}{dx^2} = \frac{1}{a \cos.^3 \varphi} = \frac{\sec.^3 \varphi}{a}.$$

Now, by formula (B),

$$\frac{y - v}{c^2} = \frac{d^2y}{dx^2} = \frac{\sec.^3 \varphi}{a};$$

therefore $y - v = \frac{c^2}{a} \sec.^3 \varphi$.

But when $x = 0$, then $v = 0$, $y = c'$, $\varphi = 0$, and $\sec.\ \varphi = 1$;

therefore $c' = \frac{c^2}{a}$ and $c^2 = ac'$; hence we have

$$v - y = c' \sec.^3 \varphi.$$

This shows that the vertical line between the intrados and extrados is always proportional to the cube of the secant of the angle which the radius OP makes with the perpendicular; a conclusion which agrees with section 25 of the preceding article.

57. The second problem, viz. having given the nature

Arch.

of the extrados, to find that of the intrados, is the more important of the two, and more difficult. Its solution requires the integral calculus; but the difficulty is no greater than that of finding the area of a curve whose equation is given. This can always be accomplished, if not in finite terms, at least by infinite series. We shall now give a general solution of the problem.

Lagrange has shown (*Théorie des Fonctions Analytiques*, chap. viii.) that the integration of the equation

$$\frac{d^2y}{dx^2}-\frac{y}{c^2}=\mathrm{X},$$

(where X denotes an explicit function of the variable x), can always be accomplished when two particular integrals of this other equation, viz.

$$\frac{d^2y}{dx^2}-\frac{y}{c^2}=0,$$

are known. Now $y=pe^{\frac{x}{c}}$ and $y=qe^{-\frac{x}{c}}$ are such integrals (p and q being arbitrary constants, and $e=2\cdot7182818$, the number whose Napierian logarithm is unity), as may be proved by differentiation; therefore, following Lagrange, to integrate the equation (B), viz.

$$\frac{d^2y}{dx^2}-\frac{y}{c^2}=-\frac{v}{c^2},$$

we assume

$$y=pe^{\frac{x}{c}}+qe^{-\frac{x}{c}}$$

for the complete integral equation; but now p and q are to be considered as functions of the variable x. To determine these, we differentiate, and get

$$\frac{dy}{dx}=\frac{1}{c}\left\{pe^{\frac{x}{c}}-qe^{-\frac{x}{c}}\right\}+e^{\frac{x}{c}}\frac{dp}{dx}+e^{-\frac{x}{c}}\frac{dq}{dx}:$$

Since p and q are indeterminate functions of x, we may assume that

$$e^{\frac{x}{c}}\frac{dp}{dx}+e^{-\frac{x}{c}}\frac{dq}{dx}=0,$$

and then we have

$$\frac{dy}{dx}=\frac{1}{c}\left\{pe^{\frac{x}{c}}-qe^{-\frac{x}{c}}\right\}:$$

Again, by differentiating, we find

$$\frac{d^2y}{dx^2}=\frac{1}{c^2}\left\{pe^{\frac{x}{c}}+qe^{-\frac{x}{c}}\right\}+\frac{1}{c}\left\{e^{\frac{x}{c}}\frac{dp}{dx}-e^{-\frac{x}{c}}\frac{dq}{dx}\right\}$$

$$=\frac{y}{c^2}+\frac{1}{c}\left\{e^{\frac{x}{c}}\frac{dp}{dx}-e^{-\frac{x}{c}}\frac{dp}{dx}\right\}.$$

This result, compared with equation (B), gives

$$\frac{1}{c}\left\{e^{\frac{x}{c}}\frac{dp}{dx}-e^{-\frac{x}{c}}\frac{dq}{dx}\right\}=-\frac{v}{c^2}.$$

From this and the equation

$$e^{\frac{x}{c}}\frac{dp}{dx}+e^{-\frac{x}{c}}\frac{dq}{dx}=0,$$

we obtain $\left(\text{putting } \mathrm{X}=-\frac{v}{c^2}\right)$

$$\frac{dp}{dx}=\frac{c}{2}e^{-\frac{x}{c}}\mathrm{X},\qquad \frac{dq}{dx}=-\frac{c}{2}e^{\frac{x}{c}}\mathrm{X},$$

$$p=\frac{c}{2}\int e^{-\frac{x}{c}}\mathrm{X}dx+b;\ q=-\frac{e}{2}\int e^{\frac{x}{c}}\mathrm{X}dx+b'.$$

Here b and b' are arbitrary constants, and the integrals are supposed to be taken so as to vanish when $x=0$. The complete integral equation is now

(C)

$$y=be^{\frac{x}{c}}+b'e^{-\frac{x}{c}}+\frac{c}{2}\left\{e^{\frac{x}{c}}\int e^{-\frac{x}{c}}\mathrm{X}dx-e^{-\frac{x}{c}}\int e^{\frac{x}{c}}\mathrm{X}dx\right\}.$$

To determine the arbitrary constants b and b', we must consider that a tangent to the intrados at the vertex is perpendicular to the vertical DH; therefore, when $x=0$, then $\frac{dy}{dx}=0$; but from the equation just found we get

$$\frac{dy}{dx}=\frac{1}{c}\left\{be^{\frac{x}{c}}-b'e^{-\frac{x}{c}}\right\}+\tfrac{1}{2}\left\{e^{\frac{x}{c}}\int e^{-\frac{x}{c}}\mathrm{X}dx+e^{-\frac{x}{c}}\int e^{\frac{x}{c}}\mathrm{X}dx\right\}.$$

Now, when $x=0$, then $e^{\frac{x}{c}}=1$, and $e^{-\frac{x}{c}}=1$; and by hypothesis the integrals $\int e^{\frac{x}{c}}\mathrm{X}dx, \int e^{-\frac{x}{c}}\mathrm{X}dx$ in this particular case vanish; therefore, when $x=0$, the last equation becomes $0=b-b'$, so that $b'=b$. But again, in the general equation (C), when $x=0$, then $y=c'$; therefore we have also $c'=2b$ and $b=\frac{1}{2}c'$. On the whole, the equation of the extrados is

(D)

$$y=\frac{c'}{2}\left\{e^{\frac{x}{c}}+e^{-\frac{x}{c}}\right\}+\frac{c}{2}\left\{e^{\frac{x}{c}}\int e^{-\frac{x}{c}}\mathrm{X}dx-e^{-\frac{x}{c}}\int e^{\frac{x}{c}}\mathrm{X}dx\right\};$$

the integrals being taken so as to vanish when $x=0$. We have thus brought the solution to depend on the integration of the two differentials

$$e^{\frac{x}{c}}\mathrm{X}dx,\quad e^{-\frac{x}{c}}\mathrm{X}dx,$$

which in fact will only differ in their sign, because the branches of the extrados on opposite sides of the vertical are exactly alike, and therefore the substitution of $-x$ for $+x$ will not change the sign of u nor of X. Now this integration can always be effected by known methods, therefore the second problem may be regarded as completely resolved.

57. *Example.* Let us suppose that the extrados is a horizontal straight line EF.

The line PT being supposed to touch the curve, let us as before put

$c'=\mathrm{DB}$, $c''=\mathrm{EA}$, $s=\mathrm{DE}$,
$x=\mathrm{DQ}$, $y=\mathrm{PQ}$, $\varphi=$ angle TPK.

In this case $v=0$ and $\mathrm{X}=0$, and the equation of the curve is simply

$$y=\frac{c'}{2}\left\{e^{\frac{x}{c}}+e^{-\frac{x}{c}}\right\}.$$

This case of the general problem has been resolved in sect. 25; the equation of the curve is, however, here given under a different form. We shall now deduce from it a formula for logarithmic calculation.

In all curves, tan. $\varphi=\frac{dy}{dx}$; in the present case

$$\tan.\varphi\left(=\frac{dy}{dx}\right)=\frac{c'}{2c}\left\{e^{\frac{x}{c}}-e^{-\frac{x}{c}}\right\}:$$

Let ψ be such an angle that

$e^{\frac{x}{c}}=\tan.(45^\circ+\frac{1}{2}\psi)$, then $e^{-\frac{x}{c}}=\tan.(45-\frac{1}{2}\psi)$.

Hence, by the arithmetic of sines (ALGEBRA, sect. 244, (K) and sect. 240, (C) No. 1),

$$e^{\frac{x}{c}}+e^{-\frac{x}{c}}=\frac{1}{\cos.(45^\circ+\frac{1}{2}\psi)\cos.(45^\circ-\frac{1}{2}\psi)}=\frac{2}{\cos.\psi}=2\sec.\psi$$

$$e^{\frac{x}{c}}-e^{-\frac{x}{c}}=\frac{\sin.\psi}{\cos.(45^\circ+\frac{1}{2}\psi)\cos.(45^\circ-\frac{1}{2}\psi)}=\frac{2\sin.\psi}{\cos.\psi}=2\tan.\psi$$

Arch.

Also, by the theory of logarithms (Algebra, sect. xix.),

$$\frac{x}{c}\log. e = \log. \frac{\tan. (45° + \frac{1}{2}\psi)}{\text{rad.}} = \log. \tan. (45° + \tfrac{1}{2}\psi) - 10.$$

From these expressions we obtain the relation of the three principal elements of the curve, viz. φ, x, y, as follows:

$$\tan. \psi = \frac{c}{c'} \tan. \varphi \ldots\ldots (1)$$

$$x = \frac{c}{\log. e}\left\{\log. \tan. (45°+\tfrac{1}{2}\psi) - 10\right\} \ldots (2)$$

$$y = \frac{c'}{\cos. \psi} = d \sec. \psi \ldots\ldots (3)$$

But before these formulæ can be applied, the value of c must be known. To find this, let α denote the value of ψ when $x = s$ and $y = c''$; then equations (3) and (2) become

$$c'' = \frac{c'}{\cos. \alpha}$$

$$s = \frac{c}{\log. e}\left\{\log. \tan. (45°+\tfrac{1}{2}\alpha) - 10\right\}$$

From these we obtain

$$\cos. \alpha = \frac{c'}{c''} \ldots\ldots (4)$$

$$c = \frac{\log. e}{\log. \tan. (45°+\frac{1}{2}\alpha) - 10} s \ldots\ldots (5)$$

These formulæ determine c, and this known, the values of x and y corresponding to any proposed value of φ may be readily found from formulæ (1) (2) and (3).

58. We may also determine y directly from x without φ by eliminating $\frac{c}{\log. e}$ by formulæ (2) and (5); we have then, to determine y from x, these formulæ,

$$\cos. \alpha = \frac{c'}{c''} \ldots\ldots (a)$$

$$\log. \tan. (45°+\tfrac{1}{2}\psi) = 10 + \frac{x}{s}\left\{\log. \tan. (45°+\tfrac{1}{2}\alpha) - 10\right\} (b)$$

$$y = \frac{c'}{\cos. \psi} \ldots\ldots (c)$$

1. As an example, let us take the case of Blackfriars Bridge, for which a table of corresponding values of x and y has been given, sect. 26. Here the span is 100 feet, the height or rise forty feet, and the thickness at the crown six feet; and first, let it be required to find the ordinate y, when $x=20$ feet; we have now

$$s=50,\ c'=6,\ c''=46,\ x=20,\ \frac{x}{s}=\frac{20}{50}.$$

Logarithmic Calculation.

$c'=6$	0·7781512
$c''=46$	1·6627578
$\cos. (\alpha=82° 30' 19'')$	9·1153934
$\log. \tan. (45°+\frac{1}{2}\alpha=86° 15' 9''\cdot5)-10=$	1·1837773
To	10·0000000
add $\frac{20}{50} \times 1.1837773 =$	0·4735109
$\tan. (45°+\frac{1}{2}\psi=71° 25' 18'')$	10·4735109
$\cos. (\psi=52° 50' 36'')$	9·7810344
$y=\frac{c'}{\cos. \psi}=9\cdot9338$ feet	0·9971168

The greater part of the above calculation serves for all the values of x, and need not be repeated in constructing a table of the ordinates.

2. Let it be required to find y when $x=32$ feet.

To	10·0000000
add $\frac{32}{50} \times 1\cdot1837773=$	0·7576175
$\tan. (45°+\frac{1}{2}\psi=80° 5' 18'')$	10·7576175
$c'=6$	0·7781512
$\cos. (\psi=70° 10' 36'')$	9·5303431
$y=17\cdot6933$ feet	1·2478081

In this way may all the numbers in the table of sect. 26. be computed with greater expedition than by the formula given there.

The value of φ to each value of x may be found from formulæ (5) and (1) of last article. (J. R.) (W. W.)

Arch, *Triumphal*, a monumental structure erected in commemoration of a victory or other memorable historical event.

These originated in ancient times in the military triumphs of the Romans, with whom it was customary to adorn the gate by which a victorious general entered the city with trophies and representations of the conquest he had achieved. These temporary memorials soon gave place to more enduring monuments of stone and marble. The triumphal arch (*Arcus triumphalis*) was built across some one of the principal streets, and consisted either of a single large archway or of a central one with two smaller ones on each side, communicating generally with the larger passage. Sometimes there were two arches of equal height side by side. Both faces of the arch and the sides of the passages were ornamented with trophies and sculptures. Above the façades, supported on columns, was an entablature surmounted by an attic crowned with figures, and bearing the inscription on its front.

The most celebrated surviving monuments of this description are the Arch of Augustus at Rimini, and another at Susa (at the foot of Mount Cenis), the arches of Trajan at Beneventum and Ancona, of Titus, Drusus, Septimius Severus, Gallienus, and Constantine, at Rome. Of these the arch of Titus is the oldest and the finest specimen of this kind of structure. It commemorates his conquest of Judæa, and is adorned with highly-finished sculptures, representing the triumphal procession of the trophies of Jerusalem. The arch of Constantine, however, is the most perfect in preservation of all the ancient Roman arches.

Remains of Roman arches are also to be seen in France, Spain, Greece, Istria, Dalmatia, and Egypt. See Orange, Rheims, Merida, &c.

In modern times structures of this kind have been erected in Italy, as that of king Alphonso at Naples; and at Berlin, at the entrance of the royal palace. The capital of France, however, possesses more of them than any other modern city. Of these the most worthy of mention are the arches of the Portes St Denis and St Martin, erected in 1673 and 1674 to commemorate the victories of Louis XIV., and the Arc du Carrousel, begun in 1806, and finished in 1809, in honour of the armies of France. This graceful monument, which forms the western entrance to the Tuileries, consists of three arches, the total height of the structure being 47 feet, and its breadth 55. The two principal faces are adorned

by eight Corinthian columns in Languedoc marble, surmounted by statues. The structure is crowned by a spirited equestrian group in bronze, consisting of a chariot drawn by four horses, guided by the allegorical figures of Victory and Peace. The marble bas-reliefs were executed by the best sculptors of the imperial epoch. But the colossal *Arc d'Étoile*, at the extremity of the *Avenue des Champs Elysées*, is the grandest monument of the kind erected in modern times. It commemorates the victories of Napoleon and his armies, and was begun in 1806, but not completed till after the Revolution of 1830. Its form is that of a parallelogram, its height and its breadth about 150 feet. It consists of three arches, the height of the central one being 95 feet, and that of the lateral arches 52. Its eastern and western fronts are adorned by colossal allegorical groups in relief; above them are bas-reliefs representing some of the most striking scenes in the imperial wars. The frieze which runs all round the structure is of the same description. The attic is adorned with bucklers inscribed with the names of victories. The interior of the arch is likewise inscribed with the names of Buonaparte and his generals. A stair inside conducts to the top of the building.

The arch at Hyde-Park Corner, surmounted by the colossal equestrian statue of the Duke of Wellington, and the Cumberland Gate, are the only representatives of this kind of structure in our country.

Arch, from the Greek ἀρχός, a prefix of many English words, used to signify chief, or of the first rank.

ARCHÆOLOGY, from ἀρχαῖος ancient, and λόγος a description. The term *Archæology*, like that of *Antiquities*, has been employed, until a very recent period, in a sense so restricted and arbitrary, as strikingly to contrast with the latitude admissible according to the original derivation of the word. Where any attempt has been made to assign precise limits, it has most frequently been reserved as the exclusive designation of Greek and Roman antiquities, though its fitness for the most comprehensive definition in relation to all which pertains to the past has not escaped the attention of scientific writers; and it is even employed by Dr Pritchard, on several occasions, as nearly synonymous with palæontology. In this use of it, however, he has not been followed, and the term is now universally adopted to designate the science which deduces history from the relics of the past. So comprehensive a subject necessarily admits of great subdivision, and some of the most important branches of the study will be found treated of under the heads of Egyptian, Etruscan, Assyrian, Mexican, Indian, Greek, and Roman antiquities.

The aspiration of the human mind after some knowledge of the mysteries of the future is not more innate or universal than the desire to recover the secrets of the past. The question *Whence?* no less than that of *Whither?* is found to give shape to the mythic legends of the rude barbarian, and to constitute an important element in the poetry and mythology which are the beginnings of every nation's oral and written history. With the progress of society the value of such indices of the past becomes apparent, and we accordingly find abundant traces of an archæological spirit in the literature of every civilized nation. The influence of the same spirit no less invariably marks every epoch of great progress. The revival of arts and letters in the thirteenth and fourteenth centuries was alike signalized by a renewed appreciation of Greek and Roman models; and while the progress of opinion in the fifteenth century was accompanied by an abandonment of medieval for classic art, the tendency of Europe in our own day, amid many elements of progress, has been singularly consentaneous in the return to medieval art, and the attempt to attain to higher excellence than has yet been achieved, by a more perfect development of the ideal of the middle ages.

It is mainly owing to the successful labours of the geologist that archæology has been so extended as to embrace the entire range of human history, and has at length been developed as a systematic science, by which the intelligent investigator is enabled to pursue his researches among records long preceding all written annals; and thereby to recover chapters in the history of nations heretofore deemed irrecoverable. The geologist, with no aid from written records, follows out his inquiries through successive periods in the history of the preadamite world, and reveals to us the character of the living beings which animated those long-past epochs of the globe. Beginning with the first traces of life in the primary fossiliferous strata, the geologist passes on from system to system, revealing a wondrous process of development, and disclosing to us marvellous revelations of long extinct being, until at length in the latest diluvial formations he points to the remains of animals identical with existing species, and even to traces of human art—the evidences of the close of geological, and the beginning of archæological periods. Here, at least, archæological science ought to be ready to take up the narrative at the close of those geological chapters; and with a minuteness of detail, and a certainty as to conclusions, unknown to the elder science. Such, however, has not been the case until very recently. The British geologist, pausing at the dawn of the historic or human period, turned to the archæologist for the remaining chapters of the history of life on our globe, and received for answer a record of Roman traces but meagrely supplementing the minuter details of recorded events. Nearly the same was the case with all historic antiquity, with the single exception of the wonderful monuments of Egypt, which still preserve to us the records of a civilization going back nearly to the emergence of our globe from the waters of the Mosaic deluge.

The traces of the primitive arts and civilization of the aborigines of Europe were long familiar to the antiquary, before any intelligent conception was formed of their value as historic records. The interpretation of these is mainly due to the successful labours of the archæologists and ethnologists of Denmark and Sweden, added to the spirited co-operation of zealous British coadjutors. By these investigators the remains of primitive art have been brought under a systematic classification, and thus the desultory and often misdirected labours of the antiquary have given place to researches characterized by a scientific accuracy in no degree inferior to that of the most careful palæontologist.

This system of Primitive Archæology is arranged into three great divisions, entitled the Stone, the Bronze, and the Iron periods, warranted alike by evidence, and by its practical convenience. The Stone Period, as the name implies, is that in which the rude aboriginal arts, which the commonest necessities of man call into operation, are assumed to have been employed entirely on such natural materials as stone, horn, bone, &c. The Bronze Period is that era of progress in which the metallurgic arts appear to have been introduced and slowly developed; and the Iron Period is that of matured metallurgic arts, and the accompanying progress consequent on the degree of civilization which is the necessary concomitant of such a state of things. All these periods embrace eras of national history concerning which no contemporary written records exist, and in relation to most of which, and especially to those of the first two periods, nearly as little is known from any other source as of the Palæozoic or Carboniferous periods of the geologist. It need not, therefore, excite surprise that the process of historic induction pursued on this basis has been called in question by historical writers of very high standing, but whose exclusive labours on the records of periods admitting of documentary evidence and charter-proof render them little disposed to sympathize in a course of induction in relation to human history, such as has in the hands of the

geologist revealed so much in relation to more ancient life. By these the system of archæological periods has been assailed as a visionary and illusive theory, without foundation in truth. That it is no baseless theory, however, is sufficiently manifest from the fact that no primitive and barbarous people has been met with in modern times, cut off from intercourse with civilized nations, among whom any knowledge of the metallurgic arts exist; and no partially civilized people, when similarly isolated, appears to have acquired the art of smelting and working the iron ore.

The Esquimaux, the Red Indians of America, and the whole widely-scattered races of the Polynesian Islands, were, when first discovered, without any knowledge of the metals, and supplied all their wants by means of implements and weapons of stone, shell, bone, or wood. The civilized Mexicans and Aztecs, on the contrary, when first visited by the Spaniards, in the fifteenth century, were familiar with the working of copper as well as gold; though totally ignorant of iron, and also retaining for common purposes many of the primitive stone weapons and implements. Greece passed from its bronze to its iron age within the period embraced in its literary history; and the mastery of the art of working the intractable iron ore is traceable with tolerable clearness in the early history of Rome, not very long before it came in contact with the transalpine barbarians. Among most of these Germanic and Celtic tribes, iron appears to have been already known when they first came in contact with the aggressive civilization of the south, and from one of them, the Norici (in whose country, in the Austrian valleys of the Danube, this metal is still wrought with the highest skill), we have reason to believe that the Romans acquired the art of making steel.

If history is only to begin, as that of our own country has been made to do, with the date of the first collision with invading Rome, then, no doubt, Stone and Bronze periods are as useless and meaningless as are the Eocene and Miocene periods, to the geologist who assigns the Mosaic deluge as the source of the earliest phenomena of his science. To those, however, who are willing to follow inductive reasoning to its legitimate conclusions, it must be apparent that it is no visionary theory, but a system founded in well-established truth, which arranges the archæological records of primitive history, and the remains of human art, into Stone, Bronze, and Iron periods. There is only one important distinction to be made in the use of such materials as a basis of inductive reasoning, and of those with which the palæontologist deals. The geological formations, with their included organic remains, obey a natural and unvarying order, and however widely apart similar formations may be found, they are assumed to be of contemporaneous origin. But, geologically speaking, the entire history of the human race is embraced in one period; while in the works of art, which form the basis of archæological induction, a new element—that of mind, or the reasoning faculty, along with the imitative and social arts—is introduced, and greatly complicates its subdivisions. The Stone period of Britain or Denmark is precisely analogous to that of the Polynesian Islands. So closely do their tools and weapons resemble each other, that it requires a practised eye to distinguish the stone axe or flint lance-head found in an ancient British barrow, from implements brought by some recent voyager from the islands of the Southern Ocean. The inference is manifestly legitimate, that in these South Sea Islanders we have examples of a people in the same primitive stage as were the aborigines of Europe during its Stone period. Chronologically, however, the Stone periods of the north of Europe and of the Pacific are probably separated by upwards of two thousand years. In like manner, the Bronze age of Mexico was still undisturbed by all later elements, when first brought into contact with the matured civilization of Europe in the fifteenth century, while the close of that of Britain preceded the first century of our era. The same rule is applicable to the primitive archæology of all countries; and a fertile source of error and misconception has already had its rise in the assumption, that because Greece and Italy, Germany, Gaul, Scandinavia, and Britain, have all had their primitive Stone and Bronze periods, therefore, the whole must have been contemporaneous. It cannot, therefore, be too strongly enforced as one of the most essential points of variance in the reasoning of the geologist and the archæologist, that the eras of the latter, though synonymous, are not necessarily synchronous, like those of the former; but that, on the contrary, nearly all the phenomena which pertain to the *natural history* of man, and to the historic development of the race, may be witnessed in their various stages in contemporary races of our own day: from the rudimentary barbarism, and the absence of all arts essential to the first dawn of civilization, to the state of greatest advancement in the knowledge and employment of such arts.

Some progress has already been made in an approximation to certain chronological data of much importance, relative to such primitive periods of the history of nations. Geological evidence of changes occurring within the historic period supplies somewhat of this important clue, when accompanied with the traces of human art; and while by the intelligent observation of such remains in the superficial strata, mingling with the fossil evidences of extinct and familiar species of animal life, the link is supplied by which man takes his place in the unbroken chain of creative existence sweeping backward into so remote a past, the evidences of matured art pertaining to periods unrecorded by history supply the later links of the same chain, and reunite the present with all former ages.

The system of primitive archæology which is found applicable to British antiquities, so closely corresponds in all its essential features to that of Europe prior to the era of authentic history, that the purpose of such an abstract as this will be most conveniently accomplished by presenting its leading points as examples of the whole; illustrating these in passing, by the analogous remains discovered in other countries. The evidences we possess of the various acquirements and degrees of civilization of the aborigines of Great Britain are derived from their ancient dwellings and sepulchres, from cromlechs, barrows, and cairns, and from the weapons, implements, personal ornaments, and pottery found inclosed in these. Valuable additions to our information are also supplied by means of such chance discoveries as agricultural, mining, and building operations frequently lead to; such as the stranded whales found in the alluvial valley of the Forth, many feet above the level of high water, and distant several miles from the present bed of the river. Along with these gigantic cetacean remains lay the proofs of contemporaneous population in the rude harpoons made of deer's horn; while the historical evidence relating to the locality, as well as the distinct remains of Roman military roads, combine to prove the era of local upheaval, apparently indicated by the geological phenomena, to have long preceded the dawn of the period of definite history, or the beginning of the Christian era.

By evidence such as this, a starting point is gained from whence we may confidently deduce the colonization of the British Islands, and of the north of Europe, at a very remote period; certainly many centuries prior to that in which our island first figures in history. The researches of the ethnologist add to our knowledge of this unrecorded period, by disclosing some of the physical characteristics of the aboriginal races, derived from the human remains found in the most ancient sepulchres, accompanied by the rudest evidences of art; and the researches of Nillson, Eschricht, and other continental ethnologists, when brought into comparison

with those which have been made in the British Isles, disclose remarkable points of resemblance in cranial conformation essentially different from those of any of the predominant races now inhabiting Europe.

The immense number of weapons and implements of stone already found in this and other countries, since attention has been more generally directed to the subject, proves that the period which they characterize must have been of very long duration. In various of the museums of Britain, and still more in those of Ireland, very large collections of such have been accumulated in a few years, while in the famous Christiansborg palace at Copenhagen the specimens of stone weapons and implements alone number nearly 4000. For the details of those relics, as well as the distinguishing characteristics of the various classes of sepulchres, the weems, or subterranean dwellings, the monolithic and megalithic monuments, &c., of this primitive period, the student who wishes to pursue the subject more minutely, must refer to the works of Hoare, Douglas, Worsaae, Ackerman, Roach Smith, Wright, Wilson, and others, as well as to the journals and transactions of the various archæological societies.

The period to which the whole of those primitive remains must be referred was unquestionably one of complete barbarism; as is sufficiently apparent from its correspondence to that which the intercourse with European voyagers is bringing to a close among the islands of the Pacific. The subterranean dwellings termed weems (Gaelic *Uamhah*, a cave), or "Pict's houses," have been frequently found, apparently in the state in which they must have been abandoned by their original occupants; and from these we learn that their principal aliments must have been shell-fish and crustacea, derived from the neighbouring sea-beach, along with the chance products of the chase. The large accumulations of the common shell-fish of our coasts found in some of these subterranean dwellings is remarkable, though with such remains have also been repeatedly found the stone quern or hand-mill, as well as the ruder corn-crusher or pestle and mortar; supplying the important evidence, that the primitive nomade had not been altogether ignorant of the value of the cereal grains.

The source of change in Britain, and throughout Europe, from this rude state of barbarism, is clearly traceable to the introduction of metals, and the discovery of the art of smelting ores. Gold was probably the earliest metal wrought, both from its attractive appearance, its superficial deposits, and the condition in which it is frequently found rendering its working an easy process. Tin also, in the south of Britain, was wrought at the very dawn of history; and, with the copper which abounds in the same district of country, supplied the elements of the new and important compound metal, bronze.

It was long assumed by all historians and antiquaries, that the beautiful bronze swords, spear-heads, shields, torques, armillæ, &c., so frequently discovered, were mere relics of foreign conquest or barter; and they were variously assigned to Egyptian, Phœnician, Roman, or Danish origin. But this gratuitous assumption has been disproved by the repeated discovery of the moulds for making such, as well as of the refuse castings, and even of beds of charcoal, scoriæ, and other indications of metallurgy, on the sites where they have been found. It has not escaped notice, however, that the transition appears to be an abrupt one from stone to bronze, an alloy requiring skill and experience for its use; and that few examples are recorded of the discovery of copper tools or weapons, though copper is a metal so easily wrought as to have been in use among the Red Indians of America. The inference from this fact, is one which all elements of probability tend to confirm, viz., that the metallurgic arts of the north of Europe are derived from a foreign source, whether by conquest or traffic, and that in the beautiful bronze relics so abundant, especially in the British Islands and in Denmark, we see the fruits of that experience which the more ancient civilization of Egypt and Phœnicia had diffused. The direct intercourse between the countries on the Mediterranean, and the Cassiterides, or Tin Islands,—as the only known parts of the British Islands are called in the earliest allusions which are made to them by Herodotus, Aristotle, and Polybius,—abundantly accounts for the introduction of such knowledge to the native Britons at a very remote period. Phœnician and Carthagenian merchant ships traded to Cornwall, centuries before the white cliffs of Albion were first seen from the Roman war-galleys. Greece, also, not improbably, proved a mediator in this all-important transfer. It has not escaped attention, that the forms of weapons, and especially of the beautiful "leaf-shaped sword," as figured on the most ancient painted Greek vases, closely correspond to the most characteristic relics of the Bronze period in the north of Europe and the British Isles.

During the later Iron Period the era of authentic history begins. There is no room for doubt that, whatever impetus the Roman invasion may have given to the working of the metals in Britain, iron was known prior to the landing of Julius Cæsar. Within this archæological period, however, the examples of Roman art, and the influences of Roman civilization begin to play a prominent part. To this period succeed the Saxon and Scandinavian eras of invasion, with no less characteristic peculiarities of art-workmanship, as well as of sepulchral rites and social usages. In these later periods, definite history comes to the aid of archæological induction, while those intermediate elements of historical re-edification, the inscriptions on stone and metal, and the numismatic series of chronological records, all unite to complete a picture of the past replete with important elements for the historian.

The connection between archæology and geology has been indicated, but that between archæology and ethnology is of much more practical value, and is every day being brought into clearer view. By the investigation of the tombs of ancient races, and the elucidation of their sepulchral rites, remarkable traces of unsuspected national affinities are brought to light; while a still more obvious correspondence of arts in certain stages of society, among races separated alike by time and by space, reveals a uniformity in the operation of certain *human instincts*, when developed under nearly similar circumstances, such as goes far to supply a new argument in proof of the unity of the human race.

The self-evident truths confirmatory of the principles upon which this system of primitive archæology is based, may be thus briefly summed up:—Man, in a savage state, is, to a great extent, an isolated being; co-operation for mutual and remote advantage, except in war and the chase, is scarcely possible, and hence, experience at best but slowly adds to the common stock of knowledge. In this primitive stage of society, the implements and weapons which necessity renders indispensable, are invariably supplied from the sources at hand; and the element of time being of little moment, the rude manufacturer slowly fashions his stone axe or hammer, or his lance of flint, with an expenditure of labour such as, with the appliances of civilization, would suffice for the manufacture of hundreds of such implements.

The discovery of the metallurgic arts, by diminishing labour, and supplying a material more susceptible of varied forms as well as of ornamentation, and also one originating co-operation by means of the new wants it calls into being, inevitably leads to social progress. The new material, moreover, being limited in supply, and found only in a few localities, soon leads to barter, and thence to a regular trade; and thus the first steps towards a division of labour and mutual co-operation are made. So long, however, as the metal is copper or bronze, the limited supply must greatly restrict

this social progress, while the facilities for working it admit of that isolation so natural to man in a rude state; and these, added to the frequent discovery of copper, in its natural condition much more nearly resembling a ductile metal than the ironstone, abundantly account for its use having preceded that of the more abundant metal.

Great experience must have been acquired in the earlier metallurgy before the iron ore was attempted to be wrought. In this, co-operation was indispensable; but that once secured, and the first difficulties overcome, the other results appear inevitable. The supply is unbounded, widely diffused, and procurable without excessive labour. The material elements of civilization were thereby acquired, and all succeeding progress might be said to depend on the capacity of the race.

The process of research and inductive reasoning thus applied by the archæologist to the traces of primitive art, and the dawn of civilization, as well as to the remains of classic art, is no less applicable to all periods. The songs and legends of the peasantry, the half-obliterated traces of ancient manners, the fragments of older languages, the relics of obsolete art,—all these are parts of what has been fitly styled "unwritten history," and furnish the means of recovering many records of past periods, which must remain for ever a blank to those who will recognize none but written or monumental evidence.

Proceeding to the investigation of this later, and, in most of the higher requirements of history, this more important branch of historical evidence, the archæologist has still his own special departments of investigation. Tracing the various alphabets in their gradual development, through Phœnician, Greek, Roman, and other sources, and the changing forms which followed under the influences of Byzantine and medieval art, a complete system of palæography, has been deduced, calculated to prove an important auxiliary in the investigation of monumental and written documents. Palæography has its own rules of criticism, supplying an element of chronological classification altogether independent of style in works of art, or of internal evidence in graven or written inscriptions, and a test of genuineness often invaluable to the historian.

Heraldry is another element of criticism by which archæology provides trustworthy canons of criticism in relation to written and unwritten medieval records. The seals and matrices, sepulchral sculptures, and engraved brasses, along with an extensive class of the decorations of ecclesiastical and domestic architecture, all supply evidence by means of which names and dates, with confirmatory collateral evidence of various kinds, are frequently recoverable. From the same sources also the changing costume of successive periods can be traced, and thus a new light be thrown on the manners and customs of past ages. The enthusiastic devotee is indeed apt at times to attach an undue importance to such auxiliary branches of study, but it is a still greater excess to pronounce them valueless, and to reject the useful aids they are capable of affording.

No less important are the illustrations of history, and the guides in the right course of research, which numismatics supply, both in relation to early and medieval times. But on this and other sections into which the study of antiquities is divided, the requisite information will be found under the several heads of research. On many of these points the historian and the archæologist necessarily occupy the same field; and, indeed, when that primitive period wherein archæology deals with the whole elements of our knowledge regarding it, as a branch of inductive science and not of critical history, is past, the student of antiquities becomes to a great extent the pioneer of the historian. He deals with the raw materials: the charters, deeds, wills, grants of land, of privileges or immunities, the royal, monastic, and baronial accounts of expenditure, and the like trustworthy documents; by means of their palæography, seals, illuminations, and other evidence, he fixes their dates, traces out the genealogical relationships of their authors, and in various ways prepares and sifts the evidence which is to be employed anew by the historian in revivifying the past. Architecture and all departments of the fine arts, in like manner, supply much evidence which, when investigated and systematized by a similar process, adds valuable materials to the stock of the historian, and furnishes new sources for the illumination of former ages. Such is a sketch of the comprehensive investigations embraced under the name of archæology, which, carried on by many independent labourers, and in widely varied fields of research, have contributed important chapters to the book of human history, and revivified ages long buried in oblivion, or at best but dimly seen through distorting media of myth and fable. (D. W—N.)

ARCHAISM, (from ἀρχαῖος, ancient), the use of an antiquated word or form of expression.

ARCHANGEL, an angel occupying an exalted rank among the spiritual intelligences. The Jewish writers place the archangels in the eighth rank of the celestial hierarchy.

ARCHANGEL, a government of European Russia, lying between Lat. 61. and 71. N. and Long. 29. and 68. E. It is bounded on the north by the White Sea and Arctic Ocean, on the west by Finland and Olonetz, on the south by Vologda, and on the east by the Ural Mountains. It comprehends also the islands of Nova-Zembla, Waigatz, and some others. Its area is estimated at 322,500 square miles, and its population in 1846 was calculated to amount to 253,000. The climate is for most part of the year intensely cold. That part of Archangel which lies within the arctic circle has a very desolate and sterile aspect, presenting little to the eye but extensive plains of sand and moss. The winter is long and severe; and even in summer the soil is frozen at a little depth below the surface. The rivers are closed in September, and scarcely thawed before July. South of the arctic circle the greater part is covered with immense forests, part with extensive lakes and morasses, and part affords excellent pasturage for cattle. Here the spring is moist, with cold, frosty nights; the summer, a succession of long foggy days; the autumn moist; and the rivers are closed from October to April. The northern districts are incapable of being cultivated, and the inhabitants support themselves by fishing and the chase. In the southern districts considerable quantities of hemp and flax are raised, but grain crops are little attended to, and the bark of trees is mixed with corn to eke out the scanty products of the harvest. The principal wealth of the government consists in its immense forests, that furnish materials for ship-building, which is carried on to a considerable extent. Their horses and cattle are diminutive, except in the district of Kholmogory, where excellent cattle are reared. The preparation of pitch and tar is an active branch of industry; and in the districts around Archangel coarse linens are manufactured to a considerable extent, as well as cordage, mats, leather, tallow, turpentine, and potash. This government is divided into eight circles, viz.:—Archangel, Chenkursk, Mezen, Cola, Onega, Pinega, Kholmogory, and Kem. Its chief rivers are the Onega, Pinega, Dwina, Mezen, Petshora, and Ousa. The population was originally Finnish, but it is now chiefly Russian, with some Samoides and Laplanders.

ARCHANGEL, a city of Russia, capital of the government and circle of the same name. It is situated on the right bank of the river Dwina, 35 miles from its mouth, in Lat. 64. 32. 8. N. Long. 40. 33. E. The entrance to the Dwina was discovered by the English navigator Richard Chancellor in 1553, when in quest of a north-eastern passage to China. The city of Archangel was founded in 1584, and derived its name from the convent of St Michael the

Archangel. It soon became the first trading port of Russia, and continued to be so till the rise of St Petersburg, when its commercial importance declined. In 1762 it received the same immunities as St Petersburg; and since that time it has been gradually recovering its former prosperity. Except the bazaar, which is an immense edifice, its buildings are almost entirely constructed of wood. It is the seat of an archbishop, and of a civil and military governor; has one Protestant and ten Greek churches; an ecclesiastical seminary with nine professors; a gymnasium; academies for navigation and engineering; and a naval hospital. The manufactures consist of linen, leather, canvass, cordage, mats, and sugar, and there are several breweries. Archangel is indebted for its prosperity principally to its situation on the Dwina, which is united by canals with the Volga on the one side, and with the Neva on the other, by which means it is the mart of a large extent of territory, some articles being transported thither even from Siberia. Its traffic varies considerably in different years, being much influenced by the demand for corn in England and other parts of Europe. Its principal exports are grain, flax, hemp, timber, linseed, iron, mats, tar, and tallow: its imports are chiefly colonial produce, woollens, cottons, and hardware. In 1847, the value of its exports was L.1,410,880. The value of its imports is always much less than that of its exports. Its harbour is at the island of Solembolsk, about a mile below the town, and is open only from July to September. A bar at the mouth of the Dwina, with only from 13 to 14½ feet of water, obliges vessels of greater draught to load and unload by means of lighters outside the bar. About twelve miles below the town, there is a government dockyard with slips for building vessels, and also some warehouses belonging to merchants in the city. The best season of their year is from the middle of July to the middle of August, before which time fogs and high winds prevail. After that period the nights become cold; and in September it is usually very stormy. There the shortest day has only 3 hours 12 minutes, the longest 21 hours 48 minutes.

ARCHBISHOP, the name of a church dignitary of the first class. Archbishops were not known in the East till about the year 320; and though there were some soon after this who had the title, yet that was only a personal honour, by which the bishops of considerable cities were distinguished. It was not till of late that archbishops became metropolitans, and had suffragans under them. Athanasius appears to be the first who used the title *Archbishop*, which he gave occasionally to his predecessor; Gregory Nazianzen, in like manner, gave it to Athanasius; not that either of them was entitled to any jurisdiction, or even any precedence, in virtue of it. Among the Latins, Isidore Hispalensis is the first that speaks of archbishops. He distinguishes four orders or degrees in the ecclesiastical hierarchy, viz., patriarchs, archbishops, metropolitans, and bishops.

The archbishop, besides the inspection of the bishops and inferior clergy in the province over which he presides, exercises episcopal jurisdiction in his own diocese. He is guardian of the spiritualities of any vacant see in his province, as the king is of the temporalities, and exercises ecclesiastical jurisdiction in it. He is entitled to present by lapse to all the ecclesiastical livings in the disposal of his diocesan bishop, if not filled within six months. Upon consecrating a bishop, he was authorized to name a clerk or chaplain, to be provided for by such bishop; in lieu of which it is now usual to accept an option. He is said to be enthroned when vested in the archbishopric, whereas bishops are said to be installed.

The ecclesiastical government of England is divided into two provinces, viz., Canterbury and York. Canterbury has the following suffragan bishoprics appertaining to it; St Asaph, Bangor, Bath and Wells, Bristol, Chichester, Lichfield and Coventry, St Davids, Ely, Exeter, Gloucester, Hereford, Llandaff, Lincoln, London, Norwich, Oxford, Peterborough, Rochester, Salisbury, Winchester, and Worcester. To York appertain the bishoprics of Carlisle, Chester, Durham, Ripon, and Manchester; to which may be added the bishopric of Sodor and Man, whose bishop is not a lord of parliament.

Till the year 1152, the archbishop of Canterbury had jurisdiction over Ireland as well as England, and was styled a *patriarch*, and sometimes *alterius orbis papa*, and *orbis Britannici pontifex*. Matters were done and recorded in his name thus,—*Anno pontificatus nostri primo*, &c. The first archbishop of Canterbury was Austin, appointed by King Ethelbert on his conversion to Christianity, about the year 598. He was also *legatus natus*. He even enjoyed some special marks of royalty; as to be patron of a bishopric, which he was of Rochester; and to make knights, coin moneys, &c. The archbishop is still the first peer of England, and the next to the royal family, having precedence of all dukes and all great officers of the crown. It is his privilege, by custom, to crown the kings and queens of this kingdom. He may retain and qualify eight chaplains, whereas a duke is allowed by statute only six. He has by common law, the power of probate of wills and testaments, and granting letters of administration. He may also grant licenses and dispensations in all cases formerly sued for in the court of Rome, and not repugnant to the law of God. He accordingly issues special licenses to marry, to hold two livings, &c., and he exercises the right of conferring degrees. He also holds several courts of judicature; as court of arches, court of audience, prerogative court, and court of peculiars.

The archbishop of York has the like rights in his province as the archbishop of Canterbury. He has precedence of all dukes not of the royal blood, and of all officers of state except the lord high chancellor. He has also the rights of a count palatine over Hexhamshire. The first archbishop of York was Paulinus, appointed by Pope Gregory about the year 622. He had formerly jurisdiction over all the bishops of Scotland; but in the year 1470 Pope Sextus IV. created the bishop of St Andrews archbishop and metropolitan of all Scotland.

Scotland, whilst episcopacy prevailed in that country, had two archbishoprics, St Andrews and Glasgow, the former of which was accounted the metropolitan, and, even before it arrived at the dignity of an archbishopric, resisted with great spirit all the attempts of the archbishops of York in England to become the metropolitans of Scotland. The sees of Argyll, Galloway, and the Isles, were suffragans to Glasgow; all the others in the kingdom to St Andrews.

Before the passing of 3d and 4th William IV., c. 37, and 4th and 5th William IV., c. 90, Ireland had four archbishoprics, viz., Armagh, Dublin, Cashel, and Tuam. By these statutes they were reduced to two, Armagh and Dublin, the diocese of Tuam being united to that of Armagh, and th diocese of Cashel to that of Dublin. The archbishop of Armagh is primate of all Ireland.

ARCHCHAMBERLAIN, an officer of the German empire, much the same with the great chamberlain in England. The elector of Brandenburg was appointed by the golden bull archchamberlain of the empire.

ARCHCHANCELLOR, a high officer, who in ancient times presided over the secretaries of the court. Under the first two races of the kings of France, when their territories were divided into Germany, Italy, and Arles, there were three archchancellors; and hence the three archchancellors formerly in Germany—who were the archbishops of Mentz, Cologne, and Treves.

ARCHDEACON, an ecclesiastical dignitary or officer, next to a bishop, whose jurisdiction extends either over the

whole diocese or only a part of it. Archdeacons are appointed by their respective bishops, and by § 27, 3d and 4th Vict., c. 27, they must have been six full years in priests' orders. Their duty is to visit their archdeaconries from time to time; to see that the churches and chancel are kept in repair, and everything done conformably to the canons, and to receive from the churchwardens representations of any matters of public scandal.

The visitation of the archdeacon may be held yearly, but is imperative every third year. The income attached to the office is very inconsiderable, but it is generally held by persons who are possessed of benefices and other preferments in the church. There were formerly 60 archdeacons in England and Wales, but by 6th and 7th Will. IV., c. 97, seven new archdeaconries were established.

Archdeacon's Court is the lowest court in the ecclesiastical polity. It is held, in the archdeacon's absence, before a judge appointed by himself, and called his official; and its jurisdiction is sometimes in concurrence with, sometimes in exclusion of, the bishop's court of the diocese. But, by statute 24th Henry VIII., c. 12, there lies an appeal from this court to that of the bishop. By the act of Will. IV., above cited, it is now, however, enacted that all archdeacons throughout England and Wales shall enjoy full and equal jurisdiction within their several archdeaconries.

ARCHDUKE, a title peculiar to the imperial house of Austria, all the sons of which are archdukes, and the daughters archduchesses.

ARCHELAUS, a celebrated Greek philosopher, born probably at Miletus about 470 B.C. He succeeded his master Anaxagoras in the school which he had founded at Lampsacus, from whence he afterwards removed to Athens. He was the last representative of the Ionian school, between which and the more practical philosophy that followed, his teaching formed a link of transition. His speculations were chiefly, but not exclusively physical, on which account he received the name of the *Physician* (ὁ φυσικός), in contradistinction to his contemporaries the Sophists, and his illustrious disciple Socrates. His opinions were, for the most part reproductions of the ideas of Anaxagoras. The following are some of the peculiar physical doctrines ascribed to him. He taught that there was a double principle of all things, namely, the *expansion* and *condensation* of the air, which he regarded as infinite. Heat, according to him, was in continual motion; cold was ever at rest. The earth, which was placed in the midst of the universe, had no motion. It originally resembled a wet marsh, but was afterwards dried up; and its figure, he said, was not flat but spherical, which he deduced from the fact that the sun does not become visible at the same time in all places. The sea he regarded as the overflowing of the waters contained within the earth. Animals were produced from the heat of the earth, and even men were formed in the same manner. All animals have a soul, which was born with them, but the capacities of which vary according to the structure of the organs of the body in which it resides. In morals he showed his approximation to the Sophists, by teaching that right and wrong are founded not in nature but on custom.

ARCHELAUS, king of Macedonia, was the natural son of Perdiccas, and ascended the throne after murdering his younger brother, the legitimate heir. His bloody usurpation, however, was followed by a reign devoted to the improvement of his kingdom and the patronage of the fine arts. He was assassinated B.C. 400 by one of his courtiers.

ARCHELAUS, the son of Herod the Great, was declared king of Judæa the second year after the birth of Christ. The dispute with his brother Antipas regarding the succession was referred to the decision of Augustus, who awarded to Archelaus half his father's territory. His brief reign was marked by great cruelty; as an instance of which is recorded his putting to death 3000 persons who had been concerned in a religious outbreak. On fresh complaints exhibited against him by the Jews, Augustus banished him to Vienne in Gaul, A.D. 6, where he died.

ARCHELAUS, the opponent of Sylla, in his wars against Mithridates. He afterwards went over to the Romans, who respected his military talents.

ARCHELAUS, the son of Apollonius, one of the greatest sculptors of antiquity, was a native of Ionia, and is thought to have lived in the time of the Emperor Claudius. He executed in marble the apotheosis of Homer. Kircher, Spanheim, and several other learned antiquaries have given a description of his work. It is now in the British Museum, having been purchased in 1819 for L.1000.

ARCHENA, a town of Murcia, in Spain. It is situated on the river Segura, at the eastern extremity of the delicious valley of Ricote, and is celebrated for its thermal springs. The waters retain a uniform heat of 112° Fahr. These springs are much resorted to, though the situation is most melancholy, and the accommodation for invalids very bad.

ARCHENHOLZ, JOHANN WILHELM VON, is best known by his "History of the Seven-Years-War," and "Life of Gustaf Vasa." Both are works of high authority. He likewise wrote a work on "England and Italy," which was also well received. He was born at Danzig in 1745, and died in 1812.

ARCHERY, the art or exercise of shooting with a bow and arrow. The word is formed of *arcus*, a bow; whence *arcuarius*, and even *arquis* and *arquites*, as they are also denominated in the corrupt state of the Latin tongue. The bow was anciently one of the principal implements of war, and the expertness of the archers often decided the fate of battles and of empires. In this island archery was greatly encouraged in former times, many statutes being made for its advancement; and the English archers became the best in Europe.

The *Artillery Company* of London, though they have long disused the weapon, are the remains of the ancient fraternity of bowmen or archers. Artillery (*artillérie*) is a French term signifying *archery*, as the *king's bowyer* is in that language styled *artillier du roy;* and from that nation the English seem to have learnt at least the cross-bow archery. We therefore find that William the Conqueror had a considerable number of bowmen in his army at the battle of Hastings, when no mention is made of such troops on the side of Harold; and it is supposed that these Norman archers shot with the arbalest or cross-bow, in which formerly the arrow, termed in French a *quadrel*, and in English a *bolt*, was placed in a groove.

Archæologia, vol. vi.

Of the time when shooting with the long-bow first began among the English, at which exercise they afterwards became so expert, there appear no certain accounts. Their chronicles do not mention the use of archery as expressly applied to the cross-bow or the long-bow till the death of Richard I., who was killed by an arrow at the siege of Limoges in Guienne, which Hemmingford mentions as having issued from a cross-bow. After this event, which happened in 1199, there appear not upon record any notices of archery for nearly 150 years, when an order was issued by Edward III., in the 15th year of his reign, to the sheriffs of most of the English counties, for providing 500 white bows and 500 bundles of arrows, for the intended war against France. Similar orders are repeated in the following years; with this difference only, that the sheriff of Gloucestershire is directed to furnish 500 painted bows, as well as the same number of white. In the famous battle of Cressy, which was fought in the year 1346, our chroniclers state that we had 2800 archers, who were opposed to about the same number of the French. The statement that the bows of the French, or rather their strings, were damaged by a shower of rain which

Archery.

fell a short time before the engagement, seems to prove that by this time we used the long-bow, while the French archers shot with the arbalest; for the long-bow, when unstrung, may be conveniently covered, so as to prevent the rain's injuring it; whereas, from the form of the arbalest it cannot be conveniently sheltered from the weather.

At the above-mentioned battle the English ascribed their victory chiefly to the archers. The battle of Poictiers was fought in 1356, and gained by the same means.

Sometimes the archers obtained great victories without even the least assistance from the men-at-arms; as particularly the decisive victory over the Scots at Homildon in 1402. In that bloody battle the men-at-arms did not strike a stroke, but were mere spectators of the valour and victory of the archers. The French historian, Philip de Comines, agrees with our own writers in asserting that the English archers excelled those of every other nation; and Sir John Fortescue says again and again, "that the might of the realme of England standyth upon archers." The superior dexterity of their archers gave the English a great advantage over both the French and the Scots. The French depended chiefly on their men-at-arms, and the Scots on their pikemen; but the ranks of both were often thinned and thrown into disorder by flights of arrows before they could reach their enemies.

Henry's *Hist.* vol. v. p. 463.

James I. of Scotland, who had seen and admired the dexterity of the English archers, and who was himself an excellent archer, endeavoured to revive the exercise of archery among his own subjects, by whom it had been too much neglected. With this view he procured the following law to be made in his first parliament, in 1424, immediately after his return to Scotland: "That all men might busk thame to be archares fra the be 12 years of age; and that at ilk ten punds worth of land thair be made bow markes, and speciallie near paroche kirks, quhairn upon halie dayis men may cum, and at the leist schute thryse about, and have usage of archarie; and whasa usis not archarie, the laird of the land sal rais of him a wedder; and giff the laird raisis not the said pane, the king's shiref, or his ministers, sal rais it to the king." But his death prevented the effectual execution of this law.

There is no act of parliament of Henry V. in relation to archery, and all the orders of Rymer till the battle of Agincourt relate to great guns, from which he seems at first to have expected more considerable advantage than from the training of bowmen. This sort of artillery, however, from its unwieldiness, from bad and narrow roads, and from other causes, was as yet but of little use in military operations. This king therefore ascribes his victory at Agincourt to the archers, and directs the sheriffs of many counties to pluck from every goose six wing-feathers for the purpose of improving arrows, which are to be paid for by the king.

In 1421, though the French had been defeated both at Cressy, Poictiers, and Agincourt, by the English archers, yet they still continued the use of the cross-bow; for which reason Henry V., as duke of Normandy, confirms the charters and privileges of the balistarii, who had been long established as a fraternity in his city of Rouen.

In the fifth of Edward IV. an act passed, that every Englishman, and Irishman dwelling with Englishmen, shall have an English bow of his own height, which is directed to be made of yew, wych, hazel, ash, or awburne, or any other reasonable tree, according to their power. The next chapter also directs that butts shall be made in every township, which the inhabitants are obliged to shoot up and down every feast day, under the penalty of a halfpenny when they shall omit this exercise.

In the 14th year, however, of this same king, it appears by Rymer's *Fœdera*, that 1000 archers were to be sent to the duke of Burgundy, whose pay is settled at sixpence a day, which was a considerable sum in those times, when the value of money was so much higher than it is at present. This circumstance seems to prove very strongly the great estimation in which archers were still held. In the same year Edward, preparing for a war with France, directs the sheriffs to procure bows and arrows, "as most specially requisite and necessary."

Archery

On the war taking place with Scotland, eight years after this, Edward provides both ordnance and archers; so that though the use of *artillery*, as we now term it, was then gaining ground, yet that of the bow and arrow was not neglected.

Richard III., by his attention to archery, was able to send 1000 bowmen to the duke of Bretagne; and he availed himself of the same troops at the battle of Bosworth.

During the reign of Henry VII., however, there appears no order relative to gunpowder or artillery; while, on the other hand, in 1488, he directs a large levy of archers to be sent to Brittany, and that they shall be reviewed before they embark. In the 19th year of his reign, the same king forbids the use of the cross-bow, because "the long-bow had been much used in this realm, whereby honour and victory had been gotten against outward enemies, the realm greatly defended, and much more the dread of all Christian princes, by reason of the same."

During the reign of Henry VIII. several statutes were made for the promotion of archery. The 8th Eliz. c. 10, regulates the price of bows; and the 13th Eliz. c. 14, enacts that bow-staves shall be brought into the realm from the Hans Towns and the eastward; so that archery still continued to be an object of attention in the legislature.

In Rymer's *Fœdera* there is neither statute nor proclamation of James I. on this head; but it appears, by Dr Birch's life of his son (Prince Henry), that at eight years of age he learned to shoot both with the bow and gun, while at the same time this prince had in his establishment an officer who was styled *bow-bearer*. The king granted a second charter to the Artillery Company, by which the powers they had received from Henry VIII. were considerably extended.

Charles I. appears, from the dedication of a treatise entitled *The Bowman's Glory*, to have been himself an archer; and in the eighth year of his reign he issued a commission to the chancellor, lord mayor, and several of the privy council, to prevent the fields near London being so inclosed as to "interrupt the necessary and profitable exercise of shooting;" as also to lower the mounds where they prevented the view from one mark to another.

Catharine of Portugal, queen to Charles II., seems to have been much pleased with the sight at least of this exercise; for in 1676, by the contributions of Sir Edward Hungerford and others, a silver badge for the marshal of the fraternity was made, weighing 25 ounces, and representing an archer drawing the long-bow (in the proper manner) to his ear, with the following inscription: *Reginæ Catharinæ Sagittarii.* The supporters are two bowmen, with the arms of England and Portugal. In 1682 there was a most magnificent cavalcade and entertainment given by the Finsbury archers, when they bestowed the titles of "Duke of Shoreditch," "Marquis of Islington," &c. upon the most deserving. Charles II. was present upon this occasion.

So late as the year 1753 targets were erected in the Finsbury fields during the Easter and Whitsun holydays, when the best shooter was styled captain for the ensuing year, and the second lieutenant.

Before the introduction of fire-arms the enemy could only be struck at a distance by slings, the bow used by the ancients, or the cross-bow; to all which the English long-bow was infinitely superior. As for slings, they never have been used in the more northern parts of Eu-

rope by armies in the field; nor does their use indeed seem to have been at all convenient or extensively practicable, for two principal reasons: in the first place, slingers cannot advance in a compact body, on account of the space to be occupied by this weapon in its rotatory motion; in the next place, the weight of the stones to be carried must necessarily impede the slingers greatly in their movements. The bow of the ancients, again, as represented in all their reliefs, was a mere toy compared with that of our ancestors; it was therefore chiefly used by the Parthians, whose attacks, like those of the present Arabs, were desultory. As for the cross-bow, it is of a most inconvenient form for carriage, even with the modern improvements; and, in case of rain, could not easily be secured from the weather. After the first shot, moreover, it could not be recharged under a considerable time, whilst the bolts were also heavy and cumbersome. The English long-bow, on the other hand, together with the quiver of arrows, was easily carried by the archer, as easily secured from the rain, and recharged almost instantaneously. It is not therefore extraordinary, that troops who solely used this most effectual weapon should generally obtain the victory, even when opposed to much more numerous armies.

It may be urged, that these losses having been experienced by our enemies, must have induced them to practise the same mode of warfare. But it is thought that the long-bow was not commonly used even in England till the time of Edward III., when the victory at Cressy sufficiently proclaimed the superiority of that weapon. It required, however, so much training before the archer could be expert, that we must not be surprised if, soon afterwards, this military exercise was much neglected, as appears by the preambles of several ancient statutes. While the military tenures subsisted, the sovereign could only call upon his tenants during war, who therefore attended with the weapons they had been used to, and which required no previous practice. On the other hand, the English archers were obliged by acts of parliament, even in time of peace, to erect butts in every parish, and to shoot on every Sunday and holyday, after repairing perhaps to these butts from a considerable distance; while the expense of at least a yew bow is represented as being a charge to which they were scarcely equal. The kings and parliaments of this country having thus compelled the inhabitants to such training, the English armies had, it should seem, the same advantage over their enemies as the exclusive use of fire-arms would give us at present.

It appears, also, by what has been already stated, that the long-bow continued to be in estimation for more than two centuries after gunpowder was introduced, which probably arose from muskets being very cumbersome and unwieldy. It is well known that rapid movements are generally decisive of the campaign; and for such the archers were particularly adapted, because, as they could not be annoyed at the same distance by the weapons of the enemy, they had scarcely any occasion for armour. The flower of ancient armies likewise was the cavalry, against which the long-bow never failed to prevail; and hence the great number of French nobility who were prisoners at Cressy, Poictiers, and Agincourt; for being dismounted, if not wounded, whilst they were also clad in heavy armour, they could not make their escape. The same reason accounts for the English obtaining these signal victories with so inferior numbers; for the nobility and gentry thus becoming prisoners, the other parts of the French army made little or no resistance. No wonder, therefore, that in England the greatest anxiety was shown to promote the exercise of this most important weapon, and that so many statutes were made for that purpose.

In Scotland, also, little less attention, though apparently not with equal success, was shown to the encouragement of the art. In both kingdoms it was provided that the importers of merchandise should be obliged, along with their articles of commerce, to import a certain proportion of bows, bow-staves, and shafts for arrows. In both every person was enjoined to hold himself provided in bows and arrows, and was prescribed the frequent use of archery. In both a restraint was imposed upon the exercise of other games and sports, lest they should interfere with the use of the bow; for it was intended that people should be made expert in the use of it as a military weapon, by habituating them to the familiar exercise of it as an instrument of amusement. As there was no material difference between the activity and bodily strength of the two people, it might be supposed that the English and Scots wielded the bow with no unequal vigour and dexterity; but, from undoubted historical monuments, it appears that the former had the superiority, of which one instance has been already narrated. By the regulations prescribed in their statute-book for the practice of archery, we find that the English shot a very long bow, those who were arrived at their full growth and maturity being prohibited from shooting at any mark that was not distant upwards of 220 yards.

In the use of the bow, great dexterity as well as strength seems to have been requisite. Though we hear of arrows at Chevy Chase which were a yard long, yet it is by no means to be supposed that the whole band made use of such, or could draw them to the head. The regulation of the Irish statute of Edward IV., viz. that the bow should not exceed the height of the man, is allowed by archers to have been well considered; and as the arrow should be half the length of the bow, this would give an arrow of a yard in length to those only who were six feet high. A strong man of this size in the present times cannot easily draw above 27 inches, if the bow is of a proper strength to do execution at a considerable distance. At the same time it must be admitted, that as our ancestors were obliged by some of the old statutes to begin shooting with the long-bow at the age of seven, they might have acquired a greater sleight in this exercise than their descendants, though the latter should be allowed to be of equal strength.

As the shooting with the long-bow was first introduced in England, and practised almost exclusively for nearly two centuries, so it has occasioned a peculiar method of drawing the arrow to the ear and not to the breast. That this is contrary to the usage of the ancients is very clear from their reliefs, and from the tradition of the Amazons cutting off one of their paps, as it occasioned an impediment to their shooting. The Finsbury archer is therefore represented in this attitude of drawing to the ear, both in the *Bowman's Glory* and in the silver badge given by Catharine to the Artillery Company.

As to the distance to which an arrow can be shot from a long-bow with the best elevation of 45 degrees, that must necessarily depend much both upon the strength and sleight of the archer; but in general the distance was reckoned from eleven to twelve score yards. The butts for exercise, as above noticed, were directed to be distant upwards of 220 yards. There is indeed a tradition, that an attorney of Wigan in Lancashire, named Leigh, shot a mile in three flights; but the same tradition states that he placed himself in a very particular attitude, which cannot be used commonly in this exercise. According to Neade, an archer might shoot six arrows in the time of charging and discharging one musket.

The archers consider an arrow of from 20 to 24 drop weight to be the best for flight or hitting a mark at a con-

siderable distance, and that yew is the best material of which they can be made. As to the feathers, that of a goose is preferred: it is also wished that the bird should be two or three years old, and that the feather may drop of itself. Two out of three feathers in an arrow are commonly white, being plucked from the gander; but the third is generally brown or gray, being taken from the goose, and, from this difference in point of colour, informs the archer when the arrow is properly placed. From this most distinguished part, therefore, the whole arrow sometimes receives its name: and this, by the by, affords an explanation of the gray-goose wing in the ballad of Chevy Chase. Arrows were armed anciently with flint or metal heads, latterly with heads of iron: of these there were various forms and denominations. By an act of parliament made the 7th of Henry IV. it was enacted, That for the future all the heads for arrows and quarrels should be well boiled or brased, and hardened at the points with steel; and that every arrow-head or quarrel should have the mark of the maker: workmen disobeying this order were to be fined and imprisoned at the king's will, and the arrow-heads or quarrels to be forfeited to the crown.

Grose *on Ancient Armour.*

Arrows were reckoned by sheaves, a sheaf consisting of 24 arrows. They were carried in a quiver, called also an *arrow-case*, which served for the magazine; arrows for immediate use were worn in the girdle. In ancient times phials of quicklime, or rather combustible matter, for burning houses or ships, were fixed on the heads of arrows, and shot from long-bows. This has been also practised since the use of gunpowder. Neade says he has known by experience that an archer may shoot an ounce of fireworks upon an arrow twelve score yards. Arrows with wildfire, and arrows for fireworks, are mentioned among the stores at Newhaven and Berwick in the 1st of Edward VI.

The force with which an arrow strikes an object at a moderate distance may be conceived from the account given by King Edward VI. in his journal; wherein he says, that 100 archers of his guard shot before him two arrows each, and afterwards altogether; and that they shot at an inch board, which some pierced quite through and struck into the other board; divers pierced it quite through with the heads of their arrows, the board being well-seasoned timber: their distance from the mark is not mentioned.

To protect our archers from the attacks of the enemy's horse, they carried long stakes pointed at both ends: these they planted in the earth, sloping before them. In the first of Edward VI., 350 of these were in the stores of the town of Berwick, under the article of archers' stakes: there were also at the same time eight bundles of archers' stakes in Pontefract castle.

To prevent the bowstring from striking the left arm, the arm is covered with a piece of smooth leather, fastened on the outside of the arm—this is called a *bracer;* and to guard the fingers from being cut by the bowstring, archers wore shooting gloves. Chaucer, in his prologue to the Canterbury Tales, thus describes an archer of his day:

And he was cladde in cote and hode of grene.
A shefe of peacock arwes bright and kene
Under his belt he bare ful thriftily.
Wel coude he dresse his takel yemanly:
His arwes drouped not with fetheres lowe.
And in his hond he bare a mighty bowe.
A not-hed hadde he, with a broune visage.
Of wood-craft coude he wel alle the usage.
Upon his arme he bare a gaie bracer,
And by his side a swerd and a bokeler,
And on that other side a gaie daggere,
Harneised wel, and sharpe as point of spere:
A Cristofre on his brest of silver shene.
An horne he bare, the baudrik was of grene.
A forster was he sothely as I gesse.

Though archery continued to be encouraged by the king and legislature for more than two centuries after the first knowledge of the effects of gunpowder, yet by the latter end of the reign of Henry VIII. it seems to have been partly considered as a pastime. Arthur, the elder brother of Henry, is said to have been fond of this exercise, insomuch that a good shooter was styled Prince Arthur. We are also informed that he pitched his tent at Mile-End in order to be present at this recreation, and that Henry his brother also attended. When the latter afterwards became king, he gave a prize at Windsor to those who should excel in this exercise; and a capital shot having been made, Henry said to Barlow (one of his guards), "If you still win, you shall be duke over all archers." Barlow therefore having succeeded, and living in Shoreditch, was created duke thereof. Upon another occasion Henry and the queen were met by 200 archers on Shooter's hill, which probably took its name from their assembling near it to shoot at marks. This king likewise gave the first charter to the Artillery Company, in the 29th year of his reign, by which they are permitted to wear dresses of any colour except purple and scarlet—to shoot not only at marks, but birds, if not pheasants or herons, and within two miles of the royal palaces. They are also enjoined by the same charter not to wear furs of a greater price than those of the marten. The most material privilege, however, is that of indemnification for murder, if any person passing between the shooter and the mark is killed, provided the archers have first called out *fast.*

The following description of an archer, his bow, and accoutrements, is given in a MS. written in the time of Queen Elizabeth. "Captains and officers should be skilful of that most noble weapon, and to see that their soldiers according to their draught and strength have good bowes, well nocked, well strynged, every strynge whippe in their nocke, and in the myddes rubbed with wax, braser and shuting glove, some spare strynges trymed as aforesaid, every man one shefe of arrows, with a case of leather defensible against the rayne, and in the same fower and twentie arrowes, whereof eight of them should be lighter than the residue, to gall or astoyne the enemye with the hailshot of light arrows, before they shall come within the danger of the harquebuss shot. Let every man have a brigandine, or a little cote of plate, a skull or hufkyn, a mawle of leade of five foote in lengthe, and a pike, and the same hanging by his girdle, with a hook and a dagger; being thus furnished, teach them by musters to marche, shoote, and retire, keepinge their faces upon the enemy's. Sumtyme put them into great nowmbers, as to battell apparteyneth, and thus use them often times practised, till they be perfecte; ffor those men in battel ne skirmish can not be spared. None other weapon maye compare with the same noble weapon."

The long-bow, as already observed, maintained its place in our armies long after the invention of fire-arms; nor have there been wanting experienced soldiers who were advocates for its continuance, and who in many cases even preferred it to the harquebuss or musket. King Charles I. twice granted special commissions under the great seal for enforcing the use of the long-bow. The first was in the 4th year of his reign; but this was revoked by proclamation four years afterwards, on account of divers extortions and abuses committed under sanction thereof. The second, anno 1633, in the ninth year of his reign, to William Neade and his son, also named William, wherein the former is styled an ancient archer, who had presented to the king a warlike invention for uniting the use of the pike and bow, seen and approved by him and his council of war; whereof his majesty had granted them

a commission to teach and exercise his loving subjects in the said invention, which he particularly recommended the chief officers of his trained bands to learn and practise; and the justices and other chief magistrates throughout England are therein enjoined to use every means in their power to assist Neade, his son, and all persons authorized by them, in the furtherance, propagation, and practice of this useful invention. Both the commissions and proclamation are printed at large in Rymer. At the breaking out of the civil war, the earl of Essex issued a precept, dated in November 1643, for stirring up all well-affected people towards the raising of a company of archers for the service of the king and parliament.

There are several societies of archers in England; but the most noted society of this kind now existing is

The Royal Company of Archers, the King's Body Guard for Scotland. The ancient records of this company having been destroyed by fire about the end of the 16th century, no authentic traces of its institution now remain; but, from entries found in some of the old national records, this company must be of great antiquity. It is believed that the Royal Company owes its origin to the commissioners appointed in the reign of James I. of Scotland for enforcing and overseeing the exercise of archery in different counties. These commissioners, who were men of rank and power, picked out from among the better classes under their cognizance, the most expert bowmen, formed them into a company, and upon perilous occasions they attended the king as his chief body guard; and in that situation they always distinguished themselves for their loyalty, courage, and skill in archery. The rank of King's Body Guard for Scotland was from tradition understood to be vested in the Royal Company, and they accordingly claimed the honour of acting as body guard to his majesty King George IV. on the occasion of his visit to Scotland in 1822. His majesty was graciously pleased to recognise their claim, and the Royal Company were thus established as the King's Body Guard for Scotland. They attended his majesty at court and on all state occasions during his residence in Scotland, and accompanied him on his visit to Hopetoun House, from whence he embarked for London. The captain-general has since been appointed gold stick for Scotland, and the Royal Company now forms part of the household.

It appears from the minutes of the Royal Company now extant, that an act of the privy council of Scotland was passed in 1677, conferring on them the name and title of "His Majesty's Company of Archers," and granting a sum of money for a piece of plate to be shot for in that year as a prize; but no *permanent* king's prize was established until 1788, when his majesty George III., as a mark of his royal patronage and favour, was pleased to grant a sum of money to be shot for annually, to be named the king's prize, and to become the property of the winner. The gainer is bound to purchase a piece of plate, on which must be inscribed the king's arms, and the date when the prize was gained.

During the revolution in 1688 the Royal Company were opposed to the principles then espoused; and for many years they had to forego their public parades, and the company in consequence had nearly been annihilated. On the accession of Queen Anne, however, their former splendour was revived; and in the year 1703 a royal charter was granted, confirming all their former rights and privileges, and conferring others upon them.

Thus the Royal Company continued to flourish for a number of years; but their attachment to the family of Stuart was the cause at various times of a temporary prosperity and decline. These unhappy differences having long since terminated, the Royal Company, which consists of the principal nobility and gentry of Scotland, are now more prosperous, and perhaps more dexterous in the art of archery, than at any former period in their history.

The prizes belonging to this Royal Company, and which are annually shot for, are, 1*st*, A silver arrow, given by the town of Musselburgh, which appears to have been shot for as early as the year 1603. The victor in this, as in the other prizes, except the king's prize, has the custody of it for a year, then returns it with a medal appended, on which are engraved any motto and device which the gainer's fancy dictates. 2*d*, A silver arrow, given by the town of Peebles A. D. 1626. 3*d*, A silver arrow, given by the city of Edinburgh A. D. 1709. 4*th*, A silver arrow, given by the town of Selkirk, which was shot for in 1819, after an interval of 144 years. 5*th*, A silver punch bowl, made of Scotish silver, at the expense of the company A. D. 1720, to which a gold medal has annually been attached. This prize can only be gained by three consecutive ends; and if not won during the summer, it is shot for as an ordinary prize at the end of the season. 6*th*, A gold medal, made of pagodas, being part of the money paid by Tippoo Sultan at the treaty of Seringapatam, and presented to the Royal Company by Major James Spens. 7*th*, An elegant silver vase and gold medal, presented by General John Earl of Hopetoun, in commemoration of the visit of George IV. to Scotland in 1822, called the royal commemoration prize, and which is shot for on the king's birth-day annually. These prizes are all shot for at the distance of 180 yards. There is another prize, which was given by Sir George Mackenzie of Coul, Bart., to the Royal Company, to be shot for at the distance of 200 yards, and is called the "Saint Andrew prize." These prizes are shot for at rovers, and, with the exception of the silver bowl, are gained by the person who counts the greatest number of points in a given number of ends.

Besides the above, there is another prize shot for, at the distance of 100 yards, being an elegant silver bugle-horn, presented to the Royal Company by one of the general officers, Sir Henry Jardine, Knt., and was shot for on 9th April 1830 for the first time.

There are also two prizes contended for at butts, or point blank distance, being 100 feet. The first is called the goose. The ancient manner of shooting for this prize was, by building a living goose in a turf-butt, having the head only exposed to view; and the archer who first hit the head was entitled to have the goose as his reward, and bore the title of Captain Goose for the season. This barbarous custom has long since been laid aside; and in place of the goose's head a small glass globe is put into the butt, of about an inch in diameter, and the archer who breaks this is declared victor, and is entertained by the company at dinner. He wears a medal which was presented by Major Spens, also made of Tippoo Sultan's pagodas. The other butt prize is a gold medal, which is shot for on the last Saturday of January, February, and March, annually, and is gained by him who counts the greatest number of points in the three days shooting.

The affairs of the Royal Company are managed by a council, consisting of seven, who are chosen annually at a general meeting of the members. The council are vested with the power of receiving or rejecting candidates for admission, and of appointing the officers of the company, civil and military.

The Royal Company consists of about 500 members. There are weekly meetings of members at Edinburgh, in the Meadows, when they exercise themselves in shooting at butts and rovers; and in the adjoining ground they have a handsome building called Archer's Hall, erected within these 50 years, where they dine, and hold their elections and other meetings relative to the business of the company.

The field uniform of the Royal Company is of dark-green cloth, faced with black braiding, with a narrow stripe of crimson velvet in the centre. The hat is of the same colour, with a handsome medallion in front, and a plume of black feathers.

The Royal Company have two standards, which are very old. The first of these bears on one side Mars and Venus, encircled in a wreath of thistles, with this motto, "In peace and war." On the other side is a yew-tree, with two men dressed and equipped as archers, encircled as the former; motto, "Dat gloria vires." The other standard displays on one side a lion rampant, gules on a field or, encircled with a wreath; on the top a thistle and crown; motto, "Nemo me impune lacessit." On the reverse side St Andrew on the Cross, on a field argent; at the top a crown; motto, "Dulce pro patria periculum."

His late Majesty King William IV. presented the Royal Company of Archers, his Body Guard for Scotland, with new colours. The one combines both the old ones, with the words, "The Royal Company of Archers;" and the other bears the Royal Arms of Scotland, with the words, "King's Body Guard for Scotland." His Majesty also expressly confirmed the appointment of the Royal Company to be "the King's Body Guard for Scotland."

ARCHES COURT. See COURT OF ARCHES.

ARCHETYPE (ἀρχέτυπος), the original model of a work of art. Among minters it is used for the standard weight by which the others are adjusted. The archetypal world, in the language of Plato, means the world as it existed in the Divine mind before the visible creation.

ARCHEUS (from ἀρχή), a term employed by Basil Valentine, Paracelsus, and Van Helmont, to denote the regulative and conservative principle of the animal world, expressed in modern language by the word *vital force*.

ARCHIACOLYTHUS (from ἀρχός and ἀκόλουθος), the chief of the acolythi. See ACOLYTE.

ARCHIATER (ἀρχίατρος), properly the chief physician of a prince, or a superintendent over subordinate physicians.

ARCHIDAPIFER (from ἀρχός, and *dapifer*), or chief sewer, was a great officer of the empire. This office belonged to the elector of Bavaria, though claimed by the palatine of the Rhine.

ARCHIDONA, a city of Andalucia in Spain, on a small stream which flows into the river Guadalorza, in the province of Granada. It is a well-built town, with one church, five monasteries, the ruins of an extensive Moorish castle, and 7611 inhabitants, chiefly engaged in the manufacture of linen and olive oil.

ARCHIGALLUS, in *Antiquity*, the chief of the Galli, or priests of the goddess Cybele.

ARCHIGERONTES (from ἀρχός, and γέρων, *old*), in *Antiquity*, the chiefs or masters of the several companies of artificers at Alexandria. Some have mistaken the archigerontes for the archpriests appointed to take the confession of those who were condemned to the mines.

ARCHIL, ARCHILLA, ROCELLA, ORSIELLE, is a whitish moss which grows upon rocks, in the Canary and Cape de Verde Islands, and yields a rich purple tincture, fugitive indeed, but extremely beautiful. It is produced from various lichens, *Rocella tinctoria*, *R. lecanora*, *Lichen tartarea*, *L. parella*, *Variolaria orcina*, *V. dealbata*, &c. This weed is imported to us as it is gathered. Those who prepare it for the use of the dyer grind it between stones, so as to thoroughly bruise, but not to reduce it into powder; and then moisten it occasionally with a strong spirit of urine, or urine itself mixed with quicklime. In a few days it acquires a purplish red, and at length a blue colour. In the first it is called *Archil;* in the latter, *Lacmus* or *Litmus*.

ARCHILOCHIAN, a term in poetry applied to the verse of which Archilochus was the inventor; consisting of seven feet, of which the first four are ordinarily dactyles, though sometimes spondees; the last three trochees.

ARCHILOCHUS, a famous Greek poet and musician, was, according to Herodotus, contemporary with Candaules and Gyges, kings of Lydia, who flourished about the 14th Olympiad, 724 years before Christ. He was born at Paros, one of the Cyclades. His father Telesicles was a man of high rank, and was chosen by his countrymen to consult the oracle at Delphi concerning the sending of a colony to Thasos. He is said, however, to have sullied his birth by an ignoble marriage with a slave called *Enipo*, of which alliance our poet-musician was the fruit. Archilochus showed an early genius and attachment to poetry and music; but disgust with his country and the conduct of Lycambes, who had promised him one of his daughters, induced him to emigrate to Thasos. In a battle against the Thracians of the continent, the young poet lost his buckler, though he saved his life by the help of his heels. "It is much easier," said he, "to get a new buckler than a new existence."

According to Plutarch, there was no bard of antiquity by whom the two arts of poetry and music were so much advanced as by Archilochus. To him is attributed particularly the sudden transition from one rhythm to another of a different kind, and the manner of accompanying those irregular measures upon the lyre. Heroic poetry, in hexameter verse, seems to have been solely in use among the more ancient poets and musicians; and the transition from one rhythm to another, which lyric poetry required, was unknown to them; so that if Archilochus were the first author of this mixture, he might with propriety be styled the *Inventor of Lyric Poetry*. To him is likewise ascribed the composition of the first *iambic poetry* in Greece, and the invention of *Epodes*. One of his hymns, written in honour of Hercules, brought him the acclamations of all Greece; for he sung it in full assembly at the Olympic games, and had the satisfaction of receiving from the judges the crown of victory consecrated to real merit. This hymn or ode was afterwards sung in honour of every victor at Olympia who had no poet to celebrate his particular exploits.

Archilochus was slain by one Calondas or Corax, of the island of Naxos; who, though he did it in fight according to the laws of war, was driven out of the temple of Delphi, by command of the oracle, for having deprived of life a man consecrated to the Muses.

The names of Homer and Archilochus were revered and celebrated in Greece, as the two most excellent poets the nation had ever produced. This appears from an epigram in the Anthology; and from Cicero, who ranks Archilochus with poets of the first class, and in his Epistles tells us that the grammarian Aristophanes, the most rigid and scrupulous critic of his time, used to say that the longest poem of Archilochus always appeared to him the most excellent. Some fragments of his poems have been preserved. These may be seen in the *Poetæ Lyrici Græci*, published by Th. Bergk, p. 467–500.

ARCHIMAGUS, the high priest of the Persian Magi or worshippers of fire. Darius Hystaspes took upon himself the dignity of Archimagus; for Porphyry tells us he ordered that after his death, among the other titles, it should be engraven on his monument that he had been *Master of the Magi*. This seems to have been the reason that the kings of Persia were ever afterwards considered to be of the sacerdotal tribe, and were always initiated into the sacred order of the Magi before their coronation.

ARCHIMANDRITE (from μάνδρα, a convent), a name applied in the Greek Church to the superior (or abbot) of a convent, especially of the first order, such as that of Mount Athos. In ancient times it was of wider application, being sometimes applied to archbishops.

ARCHIMEDES, the most celebrated of the ancient ma-

thematicians, was born at Syracuse in Sicily, about the year 287 before the Christian era. Hiero, king of Syracuse, deemed it an honour to have this philosopher for his relative and friend. History does not inform us by whom he was instructed in the rudiments of literature, but he flourished about 50 years after Euclid. It is reported that he was indebted to Egypt for much of his knowledge; but other accounts indicate that he conferred more knowledge than he received from that celebrated nation; and, in particular, Diodorus mentions that Egypt was indebted to him for the invention of the screw-pump for drawing off water: and the same author narrates that he was the inventor of several other useful machines, which conveyed his fame to every quarter of the globe. The following passage from Livy proves that he was celebrated both for the invention of warlike machines, and also for his accurate observation of the heavenly bodies: "Unicus spectator cœli siderumque, mirabilior tamen inventor ac machinator bellicorum tormentorum," &c. lib. xxiv. cap. 34. It appears also that, in Cicero's time, his skill in solving problems had become proverbial. In a letter to Atticus, he informs him that he is now freed from a difficulty, which he termed an Archimedean problem, *Ep.* xiii. 28.

Vitruvius mentions a fact which proves Archimedes's knowledge in the doctrine of specific gravity. Hiero, the king, having given a certain quantity of gold wherewith to make a golden crown, and suspecting that the workmen had stolen part of the gold and substituted silver in its stead, he applied to Archimedes to employ his ingenuity in detecting the fraud. Ruminating upon this subject when he was in the bath, he observed that he dislodged a quantity of water corresponding to the bulk of his own body; and instantly quitting the bath with all the eagerness natural to an inventive mind upon a new discovery, he ran into the street naked, crying, Εὕρηκα! Εὕρηκα! *I have found it! I have found it!* Then taking one mass of gold and another of silver, each equal in weight to the crown, he carefully observed the quantity of fluid which they alternately displaced when introduced in the same vessel full of water. Next he ascertained how much water was displaced by the crown when put into the same vessel full of water; and, upon comparing the three quantities together, he ascertained the exact proportions of gold and silver of which the crown was composed.

Archimedes's knowledge of the mechanical powers is familiar to every one. His celebrated saying with regard to the power of the lever has been often repeated,—"Give me a place to stand upon (ποῦ στῶ), and I will move the earth." In order to show Hiero the effect of mechanical powers, it is said that by means of ropes and pulleys he drew towards him a galley which lay on the shore manned and loaded. The displays of his mechanical skill at the siege of Syracuse, mentioned by Marcellus, were long deemed incredible, until the subsequent improvements in mechanics had demonstrated their practicability. He harassed the vessels of the besiegers, both when they approached and kept at a distance from the city. When they approached, he sunk them by means of long and huge beams of wood; or, by means of grappling hooks placed at the extremity of levers, he hoisted up the vessels into the air, and dashed them to pieces either against the walls or the rocks. When the enemy kept at a distance, he employed machines which threw from the walls such a quantity of stones as shattered and destroyed their vessels. In short, his mechanical genius supplied strength and courage to the city, and filled the Romans with astonishment and terror. The account of Archimedes's instrument for burning ships at a great distance by means of the rays of the sun was deemed fabulous and impossible, until Buffon invented and framed a burning glass, composed of a multitude of plane mirrors, capable of setting fire to wood at the distance of 200 feet, of melting lead and tin at 120 feet, and silver at the distance of 50 feet.

But, however eminent for mechanical invention, he was still more eminent for the investigation of abstract truths, and the deduction of conclusive demonstrations in pure geometry. Plutarch also mentions that Archimedes himself esteemed mechanical inventions greatly inferior in value to those speculations which convey irresistible conviction to the mind. His geometrical works afford numerous proofs of his success in this field of science. It is reported that he was often so deeply engaged in mathematical speculations, as both to neglect his food and the care of his person; and at the bath he would sometimes draw geometrical figures in the ashes, and sometimes upon his own body after he was anointed according to the custom of that time. He valued himself so much upon the discovery of the ratio between the sphere and the containing cylinder, that he ordered his friends to place upon his tomb a cylinder containing a sphere, with an inscription explanatory of its nature and use.

When Syracuse was taken by storm, Archimedes, ignorant of the fact, was run through the body by a soldier, while engaged in drawing a geometrical figure upon the sand. As Marcellus had given express orders that both his person and his house should be held sacred, this appears to have happened through ignorance, and therefore removes a great part of the odium from the Roman name. This event happened in the 142d Olympiad, or 212 years before the Christian era. Marcellus, in the midst of his triumph, lamented the death of Archimedes, conferred upon him an honourable burial, and took his surviving relations under his protection; but greater honour was conferred upon him when the philosopher of Arpinum, 140 years after, went in search of his long-neglected tomb. "I diligently sought," says Cicero, "to discover the sepulchre of Archimedes, which the Syracusans had totally neglected, and suffered to be overgrown with thorns and briers. Recollecting some verses said to be inscribed on the tomb, which mentioned that on the top was placed a sphere with a cylinder, I looked around me upon every object at the Agrigentine gate, the common receptacle of the dead. At last I observed a little column which just rose above the thorns, upon which was placed the figure of a sphere and cylinder. 'This,' said I to the Syracusan nobles who were with me, 'this must, I think, be what I am seeking.' Several persons were immediately employed to clear away the weeds and lay open the spot. As soon as a passage was opened, we drew near, and found on the opposite base the inscription, with nearly half the latter part of the verses worn away. Thus would this most famous and once most learned city of Greece have remained a stranger to the tomb of one of its most ingenious citizens, had it not been discovered by a man of Arpinum."

The following works of this celebrated mathematician have escaped the wreck of time:—1. *On the Sphere and Cylinder:* 2. *On the Dimension of the Circle*, or the Proportion between the Diameter and the Circumference: 3. *On Obtuse Conoids and Spheroids:* 4. *On Spiral Lines:* 5. *On the Quadrature of the Parabola:* 6. *On Equiponderants and Centres of Gravity:* 7. *On Bodies floating on Fluids:* 8. *The Arenarius:* 9. *Lemmata;* but the genuineness of this last has been doubted.

The existing works of Archimedes were printed at Basle, in a folio volume, Greek and Latin, in 1544. This is the *editio princeps.* Another edition was printed at Paris in 1615. The most complete and best is that of Torelli, printed at Oxford in 1792, folio. There is a French translation of his works by M. Peyrard; and an English translation of the *Arenarius*, by G. Anderson, London, 1784.

ARCHIMEDES-SCREW PROPELLER. See STEAM NAVIGATION.

ARCHIMIMUS, in *Antiquity*, the chief mimic actor or

pantomime, who sometimes at funeral processions represented the character of the deceased, by imitating his voice and gestures. Suet. *Vesp.* 19.

ARCHINUS of Cœle in Attica, an eminent statesman who assisted Thrasybulus and Anytus in expelling the thirty tyrants from Athens, in B.C. 403. It was by his advice that the Cadmean or Ionic alphabet was introduced into all public documents in the same year. From an allusion in Plato, Dionysius of Halicarnassus and others have fallen into the mistake of attributing to Archinus a funeral oration.—See Plato, *Menex.* p. 403; Dion. Hal. *De adm. vi dicend. in Demosth.* p. 178.

ARCHIPELAGO, called by the Turks *Ak degniz*, the white sea, to distinguish it from *Cara degniz*, the black sea, is generally applied to that part of the Mediterranean extending from European Turkey and Greece on the west, to Asia Minor on the east, and stretching southward to the island of Candia.

The name Archipelago was unknown to the ancients, and is generally supposed to be a corruption of Αἰγαῖον πέλαγος, by which name, the derivation of which is uncertain, it was known to the Greeks. (See ÆGEAN SEA.) The ancients divided it into (1.) *Mare Thracium*, the northern part, extending southward to the northern coast of Eubœa; (2.) *Mare Myrtoum*, the south-western part, washing the shores of Attica and Argolis; (3.) *Mare Icarium*, the south-eastern part, extending along the coasts of Caria and Ionia.

The navigation of this sea is rendered difficult by the many islands and rocks with which it abounds, and by the frequent occurrence of sudden squalls, especially about the equinoxes; but it has a great number of safe and commodious gulfs and bays. Besides the Cyclades and Sporades, which are the two principal groups of smaller islands, it contains Eubœa, Samos, Chios, Lesbos, Lemnos, Imbros, Samothrace, &c. All these islands are mountainous, and many of them are of volcanic formation; while others are almost entirely composed of pure white marble, for which Paros, one of the Cyclades, in particular, is so celebrated. The larger islands have some very fertile and well-watered valleys and plains. The principal productions are wheat, wine, oil, mastic, figs, raisins, honey, wax, cotton, and silk. The inhabitants are much engaged in fishing; and the coral and sponge fishery are actively prosecuted among the Sporades. Manufactures are at a very low ebb; almost the only branch carried on being that of cotton-weaving. The climate is mild and salubrious; the heats of summer being tempered by the sea breezes, while the winters are less severe than on the neighbouring mainland. The men are hardy, well-built, and handsome; and the women are noted for their beauty. The islands of the archipelago are considered to belong partly to Europe and partly to Asia. At present the Cyclades form a portion of the Greek kingdom, while most of the other islands are subject to Turkey.

The name Archipelago, which was primarily given to the Ægean Sea, is now applied to various other seas which contain numerous islands, as the Eastern Archipelago, Caribbean Archipelago, &c.

ARCHISYNAGOGUS, the chief of the synagogue, the title of an officer among the Jews, who presided in their synagogues and assemblies. The number of these officers was not fixed, nor the same in all places, there being 70 in some, and in others only one.

ARCHITECT (Latin *Architectus*, Greek Ἀρχιτέκτων from the primitive words ἀρχή, the *beginning*, *origin*, or *cause*, and τεύχω, to *contrive*, *construct*, *build*), an originator, a contriver of structures; one who designs and executes works of architecture. An architect is either civil, naval, or military. To a civil architect the term is applied simply, without the qualifying adjective, and to the others with the distinctive adjective prefixed. Architecture requires of its professor that he be both a man of science and an artist. He has to study it as a useful science and as a decorative art; the former requiring a more than ordinary knowledge of all that natural philosophy teaches, together with a technical acquaintance with the mechanical arts used in building; and the latter a fine perception of what is competent to produce pleasing effects, and in what manner they may be combined to produce grandeur and beauty. It often happens, and particularly on the Continent, where indeed they do not generally profess to be otherwise, that architects are totally devoid of all technical knowledge of the details of their profession, in which case a surveyor or supervisor is required to carry the architect's designs into execution. Such architects are little better than mere draughtsmen. In this country there is a large class of persons called surveyors, most of whom are in fact mere measurers. They too assume the office and distinction of architects, and are frequently employed as such. Country builders, again, who are for the most part simply carpenters, masons, or plasterers, are not unfrequently allowed to execute their own designs, the result of which passes with the vulgar for architecture, and their authors are also called architects. Vitruvius, who, whatever may be his merits as an historian of architecture, certainly well understood what an architect should be, requires him to be versed in almost every branch of science and art that was taught at the time he wrote.

Very few names of the architects of antiquity most deserving of celebrity have descended to us through authentic channels. Vitruvius was himself so obscure as not to be mentioned, or in any way referred to, by any ancient author whose works remain to the present time. Of the authors of the splendid architectural monuments of Egypt and India we know absolutely nothing. It is indeed but with difficulty and uncertainty that we can indicate the architects of the middle ages, the inventors and perfecters of that magnificent and beautiful style which, in the absence of a better generic name, has been called Gothic. They were mostly ecclesiastics,—frequently bishops and abbots.

When learning began to extend itself beyond the cloister, and science and the liberal arts were allowed to shed their influence on the minds of men, their application to useful and agreeable purposes became the occupation or profession of distinct classes. These had, of course, to derive reasonable emolument from their respective professions, and it was generally made in the shape of fees. Fees, however, could not be well determined in some professions, and among them in that of architecture. At first the architect was paid so much for a design, and a salary as supervisor or surveyor of its execution; but the established custom in this country now is, that the architect shall be paid a commission of five per cent. on the cost of the structure he is engaged to design and execute. For this he makes the design; an estimate of the expense, if required; a specification of everything required to be done by the builder, by contract or otherwise; with working drawings, and drawings of details. He superintends the execution of the structure, and measures and values the whole of the work if necessary, when completed, to check the builder's accounts. (W. H—G.)

ARCHITECTURE.

[NOTE.—The expressions in the following treatise, *present*, *recent*, and others implying a certain time, must be understood to have reference to or about the year 1830, when it was first written.]

History.

THE term Architecture is derived from the name of its professor, *Architect.* It is the art of contriving and constructing buildings; and the thing produced is by metonymy called by the name of the art which produces it, as the art itself is named from its professor. The word is directly from the Latin *architectura*, irregularly formed from the deponent verb *architector*, which is itself from the Greek substantive αρχιτεκτων, Latinized *architector*, *architecto*, and *architectus;* all of which are used by Latin authors. A more regular but less relevant derivation of the Latin words *architectus* and *architectura* is found in the substitution of the participles of the verb *tego*, *to cover*, &c. for the derivative of the Greek τευχω, *to build*, &c.

When architecture is spoken of simply, without a qualifying adjective, the designing and building civil and religious edifices, such as palaces, mansions, theatres, churches, courts, bridges, &c. is intended; and it is called civil, to distinguish it from naval and military architecture. Although every description of building may thus have the term applied to it, it is by common consent restricted to such edifices as display symmetrical arrangement in the general design and fitting proportions in its parts, with a certain degree of enrichment effected by means of cornices, blocking courses, and quoins, or by pillared, columnar, or arcaded arrangements. Architecture may indeed be said to bear the same analogy to building, that literature does to language. A plain brick wall covered in the ordinary way with bricks on their edges is not architectural, because it is poor, rude, and unadorned: it produces no pleasing effect, and is such as a totally uninstructed workman would construct merely to answer the purpose required of it. As man, however, is endowed by nature with a taste for beauty and elegance, mere rugged utility does not delight him; as he becomes civilized, he seeks to embellish whatever he produces, that it may give him positive instead of negative pleasure, by presenting to his sense of vision what his mind may dwell on with complacency; and he is thus disposed to avail himself of the dispositions and decorations which constitute architecture. It may be asked, what standard of beauty there is in this art, on which taste may be formed; though it must be obvious, that, like other children of the imagination, such as poetry and music, no other can be assigned than such compositions and modes of arrangement as by their harmony and simplicity attract the attention of the rudest mind, which is pleased without being conscious why, and of the most learned or practised, which discovers in them those proportions and peculiarities of form which always produce the most pleasing impressions, and appear to be dictated by nature. Painting and sculpture have, to a certain extent, their originals in the external works of nature, so that the most uncultured taste may be gratified, or otherwise, with them, as they give faithful or unfaithful representations; music is more artificial, and the taste must be cultivated to judge of and enjoy its higher productions; but architecture is purely conventional, requiring a knowledge of its system, and a mind informed as to the principles on which it depends for beauty, even to its appreciation.[1]

As it is necessary, in erecting a new edifice where an old one has stood, to remove all that was falsely constructed and insecure, if not entirely to clear out the foundations; so it is at this time necessary, in writing a treatise on architecture, to show the false grounds on which the old system is founded, and remove the false impressions which it has generally induced.

The earliest extant author on the subject is Vitruvius, who, being ignorant of any other than his native architecture, which was Roman, and generally derived from the Greek, concocted or adopted a silly fable about the origin of building, and pretends to trace from it the invention of what are called "the orders" by the Greeks; giving, however, to each a separate fable of its own. He professes to give the proportions, arrangements, and disposition of the architectural works of the latter people, and the rules by which they were composed. He describes with considerable minuteness various species of temples and other edifices of both the Greeks and Romans, and endeavours to give reasons for almost every thing connected with them. His account of the advance of man from a state of savage wildness to civilization, the discovery and acquisition of fire, and progress in the art of building, made by the early fathers of the human race, is only surpassed in absurdity by his stories of the invention and proportioning of the various columnar ordinances of which the ancients made use; if we except perhaps the fact, that this crude system has been received and propagated throughout the civilized world ever since the resuscitation of the work four centuries ago. How could a man, who evidently knew nothing of the early history of the world, of the Celtic monuments, or of the history and architecture of Egypt and the East, be supposed capable of describing the inventions and advances in knowledge of the human race? Nor is this all: How can Vitruvius be received as an authority, when it is found that he does not correctly describe any existing edifice in either Greece or Italy, and that no example of ancient architecture, either Greek or Roman, is in perfect accordance with his laws? This we shall show in its proper place, and proceed now to take a view of the rise, progress, and history of our subject, without reference to the popular system, which is based on such fallacious ground.

Origin and history of architecture.

Although it is very probable that men built houses to shelter themselves from the inclemencies of the weather before they constructed temples to the divinity, yet it must be obvious to all who have studied the early history of the human race in connection with its antiquities, and have considered the analogies afforded by the rude and simple nations of the world at the present time, and particularly by those who occupied the western side of the Americas on the discovery of those continents, that though the art of building may have originated in the personal wants of man, the science of architecture was the result of his devotional feelings and tendencies. In Egypt and in India, in Greece and in Italy, in Gaul and in Britain, in Mexico and in Peru, structures connected with the worship of the divinity existed, and still exist, of the earliest date, or rather of dates beyond the range of positive chronological information; some evincing a greater and others a less advance in taste and refinement, but all retaining some analogy, bearing upon the same point, and tending to what may be called architectural arrangement.

[1] Count Algarotti, speaking of the absence of any thing in nature on which architecture may be modelled, says, "with good reason it may be said to hold the same place among the arts, that metaphysics does among the sciences." (*Opere del* Conte Algarotti, *edizione novissima, tomo* iii p. 25.)

History.

None of those countries, however, nor any other with which we are acquainted, present any thing intended for the personal accommodation of man in the early ages; nor is there any thing in the sacred structures that could for a moment induce the idea, that the dispositions of architecture arose in the construction and composition of domestic buildings. Every thing leads rather to the belief that devotion and superstition were the originators, carriers on, and, it may be almost said, perfecters of the science.

The modern tent and marquee may be assumed as the representatives of the earliest habitations of man; at first perhaps covered with branches, then with the bark of trees, and, in a more advanced state, with the skins of animals. It would not be till men began to congregate in towns and cities for mutual defence from the aggressions of each other, that any thing more permanent than such tent-like habitations would be thought necessary, or even convenient, as most of the tribes, if not all, were nomadic. In what manner the cities were fortified, whether by being surrounded with brick walls, or with defences of earth or mud, as the forts in India are at the present day, is not for us here to inquire; but we have no reason to suppose that the houses within them were better than the hovels of the inhabitants of such places in the East now, if they were indeed so good. The rude New Zealanders are found to fortify their villages very respectably, although their habitations are mere huts; and the ancient Mexicans and Peruvians are reported by their discoverers and conquerors to have made their towns or cities very secure by means of walls and other defences, and to have had considerable structures dedicated to the divinity, while their houses were of a mean and unpretending description. It is probable that timber was principally used in the ruder ages by men in the construction of their permanent habitations, for such is the material employed by the South Sea islanders to whom we have referred; and more particularly by the simpler and less savage tribes inhabiting the Friendly and Society Islands of the same hemisphere, who, moreover, thatch their houses with the large leaves of the cocoa-nut and bread-fruit trees. This supposition is supported, too, by the general tenor of the Mosaic history, and by the command which the Israelites received to burn with fire cities whose inhabitants were given to idolatry, which would not have been an efficient mode of destruction if such materials had been employed in building them as were then used in temples; for similar commands enjoined them to "overthrow their altars and break their pillars." Deut. chap. xii. and xiii. Jericho, also, and Hazor, were *burnt* by Joshua. Even so late as the establishment of the kingdom of Israel in the person of David, that monarch is represented to have built himself "a house of cedar." There is indeed no reason whatever for supposing that the dispositions of architecture were employed for domestic purposes till a comparatively late period; and at no time in the history of the human race has the art of building been rendered so subservient to the comfort and convenience of man in civilized communities, as it is at the present day. To that assertion the remains of Herculaneum and Pompeii, for their age, give the most decisive and satisfactory evidence; and since their time the fact will not be disputed.

If what we understand by the term architecture did not originate in, or grow out of, the mode of building which men employed in the construction of their own habitations, our next object must be to discover, whether it can be deduced from the mode they adopted in arranging and constructing edifices for the worship of the divinity.

History.

The earliest intelligible record in existence makes frequent mention of the building of altars, but without temples. The first act of Noah on coming out of the ark, was to build an altar; Abraham built altars at various times and in various places; Isaac and Jacob built altars, and the latter is the first said to have set up a stone under the circumstances detailed in the 28th chapter of Genesis. On awaking after his remarkable dream, he said, "Surely the Lord is in this place"—"this is none other but the house of God"—he "took the stone that he had put for his pillows, and set it up for a pillar, and poured oil upon the top of it, and he called the name of that place Bethel;" and then dedicating it to the Deity, he said, "and this stone which I have set for a pillar shall be God's house." Jacob set up a stone again on which to ratify his agreement with Laban in the most sacred manner. In many other parts of the Old Testament, stones, or pillars as they are called in some places, were set up as witnesses and memorials of sacred engagements. In the covenant at Shechem (Josh. xxiv. 26, *et seq.*), Joshua "took a stone and set it up there under an oak that was by the sanctuary of the Lord. And Joshua said unto all the people, Behold, this stone shall be a witness unto us, for it hath heard all the words of the Lord." After the battle with the Philistines at Mizpeh, in which the Israelites were conquerors, Samuel, who had prayed for their success, "took a stone and set it up between Mizpeh and Shen, and called the name of it Eben-ezer, saying, Hitherto hath the Lord helped us." 1 Sam. vii. 12. The analogy between these stones and the cromlechs of the ancient Celtic nations is too clear not to be observed. "It is remarkable," says General Vallancey, in his *Collectanea de Rebus Hibernicis*, "that all the ancient altars found in Ireland, and now distinguished by the name of cromlechs, or sloping stones, were originally called Bothal, or the House of God; and they seem to be of the same species as those mentioned in the book of Genesis, called by the Hebrews Bethel, which has the same signification as the Irish Bothal."[1] Of these cromlechs there are three kinds, the single upright stone or pillar; the same, with another stone laid on it crosswise; and two upright stones with a third placed on them, like an entablature on two columns; and this third kind, to distinguish it from the other two, has been called by the Greek descriptive name *trilithon*. It is evident, moreover, from the sacred text, that it was customary to offer sacrifices by these pillars or cromlechs; for on the return of the ark from Philistia (1 Sam. vi. 14, 15), the kine drew the cart on which it was placed into a field "where there was a great stone; and they (the people) clave the wood of the cart and offered the kine for a burnt-offering to the Lord," having placed the ark on the stone. Now the sacrificial stone or altar at Stonehenge is immediately before the great trilithon which forms the end of the hypœthral temple within the external peribolus, and that temple itself is doubtless of the same species as those which Moses built at Mount Sinai, and directed the people to construct on their arrival in the promised land (Exod. xxiv. 4, and Deut. xxvii. 2–6), which they afterwards did under the command of Joshua, the stones or cromlechs being multiplied for special purposes. Moses and Joshua set up twelve stones (probably trilithons), because of the number of the tribes: at Stonehenge there were five. Strabo, speaking of the temples of the Egyptians, describes the most ancient as being of vast extent, but of rude workmanship, without elegance, without grace, and without embellishment of any sort. What could this have been

Plate LI.

[1] *Coll. de Reb. Hib.* tom. ii. p. 211.

History.

but the same simple combination of sacred stones which, we have found, was the earliest species of temple on record, and one of which we may presume to be the earliest, in manner if not in date, in existence? Indeed, late travellers have discovered, at Amada in Nubia, about halfway between the first and second cataracts of the Nile, a temple which consists of square piers supporting plain squared blocks of stone, which form a simple entablature, occupying the mid-distance between the ruder Celtic structure and the finished Egyptian columnar arrangement. The Egyptians had made considerable advances on the rude model to which the Greek geographer refers, when the Israelites escaped from them, having already fallen into polytheism and idolatry; and changes in faith inducing changes in form, their temples might no longer retain their monotheistic simplicity, but must be arranged with more complexity to suit the purposes of a complex religion. Lucian and Herodotus both say that the most ancient of the Egyptian temples had no statues or images in them; but the express command given to the Israelites by Moses, in the passage just referred to in Deuteronomy, that the stones to be set up, and the altar to be made, should be of whole stones, and that no iron tool should be used upon them, warrants the supposition that it was to prevent them from doing what their late masters were then accustomed to do—carve the altar and piers or pillars with images, and so fall into idolatry; and may be admitted as a proof that the Egyptians had already made the advances in architecture which we have presumed: indeed we shall find that they had actually arrived at the splendid results which the ancient capital of Egypt even at this day presents. One of the colleagues of Denon, in a dissertation on the antiquity of Thebes, in the great work of the French Institute on the Antiquities of Egypt, says, "Let us add to all these considerations (that all the historians and philosophers of Greece and Rome agree in assigning the highest antiquity to the Egyptians) that most of the edifices of Thebes bear incontestable marks of great age. This is a fact not of a nature to produce a strong impression on those who have not seen the monuments themselves, but it helps to carry conviction to the minds of those who have been able, in the places where they exist, to compare the edifices of ancient Egypt with each other."[1] He goes on to speak of the causes of their preservation, and concludes with this passage:—"It may be remarked, moreover, that most of the ancient edifices of Thebes are composed of the ruins of other monuments which had perhaps themselves become ruined by age."

But Strabo and Herodotus agree in saying that the Indian caverns or excavations were justly presumed to be more ancient than the temples of Egypt; and a learned modern antiquary (the Rev. Mr Maurice) asserts that they were made by the Celtæ. Now the architectural arrangement of these excavations, and of Hindoo architecture generally, very much resembles that of the early Egyptian works. This coincidence strengthens the supposition that they had a common origin, and that indeed the forms of architecture originated in the simple combinations which we see in what are called the Celtic or Druidical remains; and it is not doubted that they originated in devotional feelings.

In assuming Stonehenge to be the oldest architectural monument (in manner, it may be, rather than in the date of its execution), we do not pretend to lower the antiquity of any other, but to put this beyond them all; believing it to be a specimen of primeval columnar architecture, which led the way, as one of the numerous gradations, some of which may have left no traces on the face of the earth, from the monolithic cromlech to the Parthenon of Athens, the Pantheon of Rome, and the Minster of York. It is not a sufficient argument against this assumption, that such structures are not found existing in the East at the present time; for they were doubtless swept away to make room for more ornate edifices, as the custom was, in the same sacred places, and to furnish materials for them; as the latter have in many cases been as completely obliterated from the face of the earth, with the cities to which they belonged. A specimen of the next step in advance exists in the temple at Amada; and, as we shall have occasion to show, it seems to demonstrate the truth of our position, by some of its square piers having been sculptured into cylinders, which exhibit the simplest form of the Greek Doric column.

This, however, is not the generally received opinion. It is thought that the trunks of trees used in the construction of human habitations first suggested the idea of columns; and that the lintels, transverse beams, wall-plates, and rafters, first furnished that of an entablature. Neither authentic history nor analogy appear to us to bear this out; for the most ancient architectural remains, in various places, accord less with the arrangements consequent on such an origin than those which are more modern; and it requires a great stretch of fancy to imagine the derivation of the Titanic structures of Thebes, Pæstum, and Selinus, from the posts of a woodman's hut. But the inquiry, being more curious than instructive, is not worth pursuing further; for indeed no useful result could arise from its determination.

Such being the case, we now proceed to trace the progress of the science from its earliest regular formations, of which we have sufficient and authentic information, down to the present day.

Indian architecture.

Indian chronology being so vague and undefined, and the connection of the Hindoos with the civilized nations about the Mediterranean Sea having been so much restricted in the earlier ages that we can get little assistance from the Greek historians on the subject, the date of their architectural monuments can be determined only by analogy. That, however, is an uncertain guide, especially in the circumstances in which we are placed, without proper delineations, and indeed without any work that gives a competent idea of them. Though we have held India so long, and by a so much more honourable tenure than the French did Egypt, if we were now to be dispossessed we should leave nothing, and we should certainly retain nothing, to show to our credit that we had ever held it. Such an undertaking as the great work of the French Institute on the Architectural Antiquities of Egypt is far beyond the means of individuals; the constitution of our government appears to preclude the application of funds from the public purse to such purposes; and the East India Company, from whom perhaps something of the kind on the archæology of India might have been expected, have, it would appear, occupations of more interest to them than the advancement of science and art. It may be generally stated, that, in its leading forms and more obvious features, Hindoo architecture strongly resembles Egyptian, and may be considered as of the same family with it.

Egyptian architecture.

No nation that ever existed within the annals of the human race has left structures that, in extent, magnificence, and grandeur, can vie with those of ancient Egypt. We have the authority of historians for believing that

[1] *Description de l'Egypte*, tome i. p. 432.

History.

there were others in the same country which no longer exist, that must have surpassed those which do remain; and they speak also of the cities of Assyria, as unparalleled in the extent and splendour of their edifices, whose sites, even, are not now determinable. The pyramids, however, mausoleums of a nation—and the temples, monuments of human folly—speak more strongly than any historian can, and compel our belief of what they have been by what they are; whereas the others do not exist but in name. Nineveh and Babylon were—but Thebes and Memphis still remain. It is strange, indeed, that a people who displayed such energies in the construction of tombs, pyramids, and temples, should have left no work of any description that could be applied to any really useful purpose. Denon, speaking of Thebes, says, "Still temples—nothing but temples—not a vestige of the hundred gates, so celebrated in history; no walls, quays, bridges, baths, or theatres; not a single edifice of public utility or convenience. Notwithstanding all the pains I took in the research, I could find nothing but temples, walls covered with obscure emblems, and hieroglyphics which attested the ascendency of the priesthood, who still seemed to reign over the mighty ruins, and whose empire constantly haunted my imagination."[1] Champollion, however, in his late researches, speaks of the remains of quays, and calls some of the structures palaces instead of temples; but as the former exist only in connection with the latter, they can hardly be considered as any thing more than mere embankments; and the regal and hierarchical offices having been so closely connected in the economy of ancient Egypt, it is of little or no consequence to our position whether the same edifices be called palaces or temples. Diodorus Siculus says, in one place, that "Busiris," believed to be one of the Pharaohs who persecuted Israel, "built that great city which the Egyptians call Heliopolis and the Greeks Thebes, and adorned it with stately public buildings and magnificent temples, with rich revenues;" and that "he built all the private houses, some four, and others five stories high."[2] Shortly after, speaking of Memphis, to account for the splendour with which the Egyptians built their tombs, and the comparative meanness of their houses, the same author says, "They call the houses of the living inns, because they stay in them but a little while; but the sepulchres of the dead they call everlasting habitations, because they abide in the grave to infinite generations. Therefore they are not very curious in the building of their houses; but in beautifying their sepulchres they leave nothing undone that can be thought of." Strabo also speaks of a splendid dwelling which was erected for the priests at Heliopolis, but that probably was one of the sacred palaces just referred to; for none of the ancient writers describe the domestic structures of the Egyptians, from personal knowledge of them, as being worthy of any notice; and that assertion of Strabo is too loose and unsupported by contemporary authority or analogy to deserve confidence of itself. To the statement of Diodorus, that private houses were built to four and five stories high, we can give no credence whatever; for the construction of edifices in tiers or stories was very imperfectly understood even in his time, which was many centuries after the destruction even of Thebes; and none of the existing remains of that city give the slightest indication of a second story, or indeed of aptitude to construct one, except the rude landings in some of the propylæa. Herodotus says that the Egyptians were the first who erected altars, shrines, and temples; but of their private houses he says nothing; neither does he describe any of the temples as they existed in his time in Egypt; so that he in fact affords no assistance in determining the comparative antiquity of the various architectural structures which remain to the present time in that country. Indeed the ancient historians and topographers speak for the most part so widely of dates and dimensions, that they are, at the best, most unsatisfactory, if not fallacious, guides; and in the present case, that of Egypt, the style of architecture is so uniform, or so imperfectly understood, that no argument can with safety be drawn from it, as there may in other cases. In Hamilton's *Ægyptiaca*, the author says, with reference to this question: "In Egyptian architecture there is an uniformity of structure, both in the ornaments and in the masses, which, if unassisted by other circumstances, reduces us to mere conjecture; and that not only for the difference of a century or two, but perhaps for a thousand years."[3] Again: "The monuments of antiquity in Upper Egypt present a very uniform appearance; and his first impressions incline the traveller to attribute them to the same or nearly the same epoch. The plans and dispositions of the temples bear throughout a great resemblance to one another. The same character of hieroglyphics, the same forms of the divinity, bearing the same symbols and worshipped in the same manner, are sculptured on their walls from Hermopolis to Philæ. They are built of the same species of stone; very little difference is discernible in the degrees of excellence of workmanship, or the quality of the materials; and where human force has not been evidently employed to destroy the buildings, they are all in the same state of preservation or decay."[4] But we are fortunately now about to be rid of that difficulty by the erudition and industry of those learned men who have given their attention to the hieroglyphic literature of the Egyptians. M. Champollion professes to have determined the date of every monument of antiquity in that country which is inscribed, by the inscriptions, which he has qualified himself to read. As yet, however, we are not in possession of the whole result of his discoveries.

Hypogea, or spea, being caves formed by excavation, are of earlier date than any existing structures. Internally they present square piers, which were left to support the superincumbent mass of mountain or rock when their magnitude rendered it necessary. These were originally tombs; and the cave of Machpelah, of which Abraham made the purchase as a burying-place for his family, was, doubtless, one of that kind. Oratories or chapels were afterwards made in the same manner, but, it would appear, not until columnar architecture had come into use; for their entrances are generally sculptured into the resemblance of the front of a rude portico, or an actual portico or pronaos is constructed before them. Many such are found on the banks of the Nile, in its course through Nubia and Egypt. At Ibrim, which the Greeks call Primis, in the former country, there are several of these cavern temples, the earliest of which, according to M. Champollion, bears date of the reign of one of the Pharaohs, who was contemporaneous with Abraham, or his son Isaac, or about eighteen centuries before Christ; the latest is of the time of Rhameses Sethos, the Sesostris of Greek history. To some of the cavern tombs and temples in Upper Egypt M. Champollion accords even a still higher degree of antiquity. The earliest columnar structures which are found within the same range of country do not appear to bear a higher date than that of the

[4] Ibid. p. 18.

earliest kings or Pharaohs of the eighteenth dynasty of Manetho, which began about the time of the Jewish patriarch Abraham and ended with the Pharaoh from whom his descendants escaped under the conduct of Moses. The temple at Amada, to which we have already referred, is of the time of Moeris, who was contemporary with the patriarch Jacob, and consists of twelve square piers or pillars, and four columns, which possess the form and character of the Greek Doric, and may it is suggested, be called *protodoric*. The same intention, if it may be so called, is found in others of the early monuments, but in none so perfect as in this, as almost all the structures of ancient Egypt were either destroyed or seriously damaged by the Persians at the time of their invasion under Cambyses; and they are supposed not to have ascended the Nile much above Psalcis or Dakkè, but to have turned off by the way across the desert to Ethiopia, so that the temple at Amada, which is considerably above Dakkè, escaped.

Of all the Pharaohs, Sesostris, the first of the nineteenth dynasty, was the most distinguished for the great and extensive works he executed in architecture. Most of the existing ruins in Egypt, anterior to the Persian invasion, are attributed to that monarch by M. Champollion. The immense ruins at Thebes, which have been called the Memnonium and the tomb of Osymandyas, and are popularly called Medinet Abou, are considered by the same inquirer to be those of the Palatial Temple of Rhameses the Great, or Sesostris, and which he therefore calls the Rhamesseion, the ruins at Luxor being those of the Memnonium; that edifice or series of edifices having been constructed by Amenophis Memnon, of the eighteenth dynasty, one of the good and beneficent princes by whom the children of Israel were protected during their sojourn in Egypt. The magnificent structure at the village of Carnack, within the same city, appears however to excel all the rest in extent and grandeur, and is at least their equal in antiquity. It is generally known as the temple of Carnack, but it has been distinguished as that of Jupiter Ammon. It bears inscribed the name of Thothmosis II., the predecessor of Amenophis Memnon. From the existing remains of Thebes, and the relations of historians combined, that city may be assumed to have attained its highest degree of splendour in the time of Sesostris; few of the ruins it presents being of later date than the time of that monarch. This being admitted, and we believe it can hardly be denied, it must be admitted also that the practice of architecture, and of the allied mechanical arts, were already well understood; for the composition of the monuments displays an exquisite combination of simplicitly and harmony, which produce the finest effects of beauty and grandeur; while their construction is the apparent result of perfection in the use of mechanical powers. All the Pharaonic monuments, indeed, throughout Egypt and Nubia, are wonders of science and art. The structures of Ombos, Apollinopolis Magna, and Latopolis, between Thebes and the cataract, M. Champollion determines to be generally of the age of the Ptolemies, and some even of the Roman dominion; those, however, which are of comparatively modern date are evidently restorations; others, probably of the earliest ages, having occupied the same sites. Indeed M. Champollion asserts generally that the Ptolemies, and the Ethiopian Ergamenes himself, only rebuilt temples where they had already stood in the times of the Pharaohs, and to the same divinities that had always been worshipped there; and he remarks, that the religious system of this people was such a complete whole, so connected in all its parts, and fixed from time immemorial in so absolute and precise a manner, that the dominion of the Greeks and of the Romans did not produce any innovation; that the Ptolemies and the Cæsars only restored in Nubia what the Persians had destroyed, and rebuilt temples where they had formerly stood, and dedicated them to the same gods.

Of the arrangements of an Egyptian temple we shall speak when we come to treat of Egyptian architecture as a style. In construction the Egyptians appear to have used wrought stones at a very early period: this probably was induced by the still earlier habit of excavating rocks to form tombs; for the walls in their oldest structures are composed of rectangularly cut blocks in parallel courses; whereas we shall find that the most ancient specimens of walling in Greece and Italy are not so. In the Pharaonic monuments, besides walls built in parallel courses of wrought stone, we find squared piers also; and frequently, in the same structure with them, the peculiarly formed tumescent column with a bulbous capital or head, covered with an abacus or square tablet, corresponding with the size of the piers, and warranting the supposition that that species of column is a mere refinement on the simple square pillar. What dictated its singular form must remain matter of speculation. The cylindrical column with a bell-shaped capital was the next advance, and that also is found in the same structures, though not in the simplest and earliest of them, in which piers occur. Terminal or Caryatic figures are common in those early works, not absolutely supporting an entablature, but placed before piers which do so, and having the appearance of doing it themselves when seen in front. Bold, massive, rectangular architraves extend from pier to pier and from column to column, and are generally surmounted externally by a deep coved coping, or cornice, with a large corded and torus-formed moulding intervening. This masks the ends of the stones which are placed transversely on the architraves to form the ceiling internally, the whole being flushed square on the top, and forming a flat terrace or floor. The pyramidal form of the moles or propylæa, peculiar to Egyptian temples, may have been suggested by the pyramids, as neither that form nor those adjuncts to a temple appear to have been used before the period at which it is supposed the former were constructed. The grandeur and dignity inherent to that form would indeed hardly be suspected till its appearance in the pyramids themselves; and certainly the impression of its effect must have been strong, to induce men to seek it in a truncated pyramid under a very acute angle, as in the propylæa, relying on the tendency of its outline alone. It was gradually, too, that this tendency was generally applied, for in the earliest Pharaonic structures the vertical outline is most common, except in the propylæa, where they exist; and in the structures of the Ptolemies the inclined outline pervades every thing. The monolithic obelisk is of Egyptian origin also. Its tapering form may be the consequence of the impression the pyramidal tendency had occasioned, though perhaps the object itself is the representative of the single stone by which religious feeling appears first to have expressed itself. Obelisks were set up by the Egyptians, sometimes in the courts or atria of their temples, and sometimes before the entrances to them.

Of all the architectural works of the Egyptians, however, none have excited so much the wonder and curiosity of men as the pyramids themselves; not in consequence of any particular beauty in their composition, or ingenuity in their construction, but simply because of their immense magnitude, and unknown use, and antiquity. Denon makes the following observation on his first visit to the great pyramid of Gizeh, at Memphis. "If we reflect upon these pyramids, we shall be inclined to think the pride that constructed them greater even than these masses them-

selves, and shall scarcely know whether to reprobate most the insolent tyranny which commanded, or the stupid servility of the people which executed, the undertaking. None but sacerdotal despots would ever have undertaken them, and none but a stupid fanatical people would ever have built them....The most honourable reason that can be assigned for their erection is the emulation of man to excel the works of nature in immensity and duration, and in this project he has not been altogether unsuccessful. The mountains near the pyramids are not so high, and have suffered more from time than the pyramids themselves."[1] But Memphis itself was of late foundation in comparison with other cities on the Nile. According to Professor Heeren,[2] civilization descended by the Nile from Ethiopia with the caste of priests who brought with them the worship of Ammon, Osiris, and Phtha (the Jupiter, Bacchus, and Vulcan of the Greeks), and " the spread of this worship, which was always connected with temples, affords the most evident vestiges of the spread of the caste itself; and those vestiges, combined with the records of the Egyptians, lead us to the conclusion that this caste was a tribe which migrated from the south, above Meroe, in Ethiopia, and, by the establishment of inland colonies around the temples founded by them, gradually extended and made the worship of their gods the dominant religion in Egypt. Proofs of the accuracy of this theory," he asserts, " may be deduced from monuments and express testimonies concerning the origin of Thebes and Ammon from Meroe; that it might indeed have been inferred from the preservation of the worship of Ammon in this last place." The same author goes on to say, that " Thebes was, if not the most, one of the most, ancient cities of Egypt;" and that " Memphis and other cities of the vale of the Nile are known to have been founded from Thebes." Now Thebes exists to the present time in the ruins of her magnificent temples, the works of the Pharaohs, but without the vestige of a pyramid, so that it may be concluded that none was ever built there; and Memphis may be said to exist in the everlasting pyramids of Gizeh and Saccharah, which occupy two of its extremities; but no indication remains of the existence of a temple of any kind: indeed the exact site of the city cannot be determined except by the pyramids. Herodotus, however, speaks of temples at Memphis, particularly of that of Vulcan or Phtha; but certainly no vestige of such has existed for a long period of time within that vicinity. Memphis was a great and ancient capital, and why should it not retain some evidence of the existence of temples in it? But Thebes was a greater and more ancient capital, and indeed the metropolis of all Egypt; and why has it no pyramids? These things are equally unaccountable and inexplicable, affording groundwork for almost any theory, but giving perfect support to none. Mr Hamilton, in his *Ægyptiaca*, before quoted, places Memphis considerably further south, where some ruins have been discovered which may be thought to give a colour to his supposition. But the ruins are of very inconsiderable extent, and are all prostrate, so that nothing can be positively determined by them; and the statement of Pliny as to the relative distances of the Nile and the city from the pyramids of Gizeh being proved to be correct in the one, may be admitted in the other. If Herodotus's account of the building of the pyramids be received, they are of comparatively modern date, the oldest having been constructed several generations after the time of Sesostris, under whom Thebes attained its highest degree of splendour; but this would leave unaccounted for the tendency to pyramidal forms in Egyptian architecture before referred to, unless every example exhibiting that tendency were itself referred to a date posterior to that assigned to Cheops and Cephron, which cannot be done in accordance with the assertions of M. Champollion as to the structures of Thebes, Elephantina, and Nubia generally.

From its immense size, the dimensions of the great pyramid of Gizeh, at Memphis, are variously given by the various persons who have measured it. M. Nouet, who was of the French commission in Egypt, and had perhaps the best means of ascertaining the truth, states its base to be a square whose side is 716 French or 768 English feet in length, which is about the extent of the great square of Lincoln's-Inn-Fields in London; and its height 421 French or 452 English feet, or about one-third as high again as St Paul's Cathedral. It is built in regular courses or layers of stone, which vary in thickness from two to three feet, each receding from the one below it to the number of 202; though even this is variously stated from that number to 260, as indeed the height is given by various modern travellers at from 444 to 625 feet. And the ancient writers differ as widely, both among themselves and from the moderns. On the top course the area is about 10 English feet square, though it is believed to have been originally two courses higher, which would bring it to the smallest that in regular gradation it could be. It is a solid mass of stone, with the exception of a narrow corridor leading to a small chamber in its centre; and a larger ascending corridor or gallery, from about half the distance of the first to another larger chamber at a considerable distance, vertically above the former, in which there is a single granite sarcophagus, not more than large enough for one body, putting the intention of the structure clearly beyond doubt. The other pyramids differ from that of Cheops (as the largest is called) in size, and slightly in form and mode of construction, some having the angles of the steps or courses of stone worked away to an inclined plane, and some not diminishing in a right line. One of the middle-sized pyramids is unlike all the rest, in being neither smooth nor in small steps, but in six large benches or stages, apparently of equal height, and diminishing gradually. But the circumstance which most distinguishes it is, that it is constructed of rude unshapen blocks of stone, cemented together with a very large proportion of mortar. Another is of unburnt brick, and has consequently become ruinous and mis-shapen.

The famous labyrinth, of which Herodotus speaks as having been built by the twelve kings of Egypt, beyond the Lake Mœris, is believed by Denon, after examination of the described site, to be little better than fabulous, and that the historian was imposed on by the priests, from whom he derived most of his information. He says, indeed, that he saw and examined it himself; but his description is so vague, that an architect who should endeavour to make a design from it, would be greatly embarrassed. As we can therefore derive no information from it with regard to architecture, it need not be further discussed here. It has been suggested as probable, and indeed the opinion has been maintained, that the pyramids stand over immense substructures; that their areas are occupied by chambers, in which may be found the arcana of Egyptian lore, of which they are the depositories. If it really be so, may not the labyrinths just referred to have been under the pyramid, which the historian says was constructed at the point where the labyrinth terminates, instead of near it? His expression is so ambiguous, that it leaves room for a suggestion of the kind.

Of the domestic architecture of the Egyptians we have

[1] *Voyage dans la Basse et la Haute Egypte*, p. 77. Par V. Denon.

[2] *Manual of Ancient History*, p. 58.

History.

no knowledge whatever. The statements of the ancient writers on the subject have been already mentioned; but supposing them to be more explicit, and more in conformity with probability, than they really are, without existing remains we could form but a very imperfect idea of what it was. Reasoning from analogy, and the slight information of historians, we should conclude that the habitations of the Egyptians were of a very unpretending description. The already quoted statement of Diodorus Siculus, that "they are not very curious in the building of their houses," even in his time, after their long intercourse with Greece, and their more recent connection with luxurious Rome; added to the fact, that no indications of domestic structures exist in any part of the country, and that the presumed habitations of the priests, in the ancient temples, are small and inconvenient cells; and all these things, taken in conjunction with the mildness of the climate and the salubrity of the atmosphere, we think it must be admitted, warrant the conclusion.

No style of architecture of which we have any knowledge is so well qualified to produce impressive effects on the mind as the Egyptian. The mere assumption of its forms, however, is not sufficient to produce its effects; and drawing is more incompetent to convey an idea of it than perhaps of any thing else in art. To this point the authors of the great work of the French Institute on the antiquities of Egypt bear testimony in strong language. Speaking of the incompetence of drawings to convey just ideas of the grandeur, magnificence, and beauty of the Egyptian temples, and other remains of antiquity, they say, "Despite the care we have given ourselves to describe the Egyptian monuments, we cannot even hope that we have succeeded in giving to others the ideas which we ourselves received from actual views and present contemplation of them; for there are things which drawings and descriptions cannot convey. Geometrical drawings are without doubt quite competent to show the form and proportions of an edifice, its disposition and distribution; but far indeed are they from giving satisfactory ideas of the elegance and effect of structures. Frequently we had to regret how much of the beauty of the original was lost in its geometrical representation on paper; for what in execution was light and graceful, often in the geometrical drawings appeared heavy and inelegant."[1]

The materials used in the construction of the Egyptian architectural monuments are, for the most part, granite, breccia, sandstone, and unburnt brick. The granite was principally supplied by the quarries at Elephantina and Syene, for which the Nile offered a ready mode of conveyance; some species were brought down the river from Ethiopia, but we do not find that the materials were at any time brought from any other foreign country. It may be remarked, too, that in the earliest structures the common *grès* or sandstone is principally employed. Excepting the obelisks and some few of the propylæa, all the temples at Thebes are of that material. In Lower Egypt, on the contrary, and in the works of later date generally, almost every thing is constructed of granite.

Persian, Assyrian, and Phœnician architecture.

Herodotus informs us that the ancient Persians had neither statues, temples, nor altars; and Diodorus Siculus affirms that the palaces of Persepolis and Susa were not built till after the conquest of Egypt by Cambyses, and that they were constructed by architects of that nation. In this case, as in that of India, we are at a great loss for evidence. The Persepolitan remains, though frequently visited and slightly sketched, have not been explored and delineated by such men as Stuart and Revett, or the authors of the great French work we have so often alluded to. That the Persian style, though very different in particulars, does bear a relation to the Egyptian family, however, is very evident. Sir Robert Ker Porter, in his travels in the East, says that the first impression he received in his first walk among the ruins of Persepolis was, that "in mass and in detail they bore a strong resemblance to the architectural taste of Egypt."[2] Nevertheless, there is a strong probability that the Persian is itself an original style, and that the resemblance is merely fortuitous, similar results arising from the same causes, as in Egypt and India; for the eastern parts of that country are believed to have been the earliest seat of the human race. Professor Heeren says of Persia, "It cannot be doubted, that long before the rise of the Persian power, mighty kingdoms existed in these regions, and particularly in the eastern part of Bactria; yet of those kingdoms we have by no means a consistent or chronological history—nothing but a few fragments, probably of dynasties which ruled in Media properly so called, immediately previous to the Persians;"[3] from whom the style of architecture may be derived, though indeed we know of no remains of earlier date than those which are properly called Persian. But we may be said to know nothing of Bactria; it may, and probably does, rival Elora, Salsette, and the banks of the Nile, in primitive specimens of architecture.

We have neither historical nor archæological information that can be depended on to prove what the state or style of architecture was among the ancient Assyrians. Lucian says, however, that their temples were less ancient than those of Egypt. The ruins believed to be those of the great capital of Babylonia present nothing but shapeless masses of brick, from which no idea whatever can be formed as to the style of architecture, or the progress it had made in that country; but some cylindrical and other seals and fragments, in *terra cotta*, found by excavation among those ruins, and now in the British Museum, are sufficiently in accordance with the rest of the eastern antiquities to be received as evidence of the general assimilation of its style of design with that which was common to the neighbouring nations.

The Phœnicians, we are told by Lucian, built in the Egyptian style; but their country retains no memorials of its ancient architecture by which we might confirm or correct his information. Doubtless Carthage and the other colonies of Phœnicia followed their parent country in this particular.

As far as we can judge from the trifling documents we possess of the architecture of the ancient Mexicans and Peruvians, it was of a rude but massive character, and may be thought also to resemble the early architecture of India, Egypt, and Persia more than we can see any reason for, except in the tendency of the mind of man to the same result when he is placed under similar circumstances. An impression to this effect appears to have been made on Humboldt, who, when speaking of a pyramidal mass of ancient Mexico, says, "It is impossible to read the descriptions which Herodotus and Diodorus Siculus have left us of the temple of Jupiter Belus, without being struck with the resemblance of that Babylonian monument to the *teocallis* of Anahuac."[4]

It is an illustration of the fact that the wants and fancies of man lead him to nearly the same results as he becomes civilized, without communication and consequent imitation, that the plans given by Sir William Chambers, of Chinese public and private buildings, might be taken

History.

at the first glance, for either Hindoo, Greek, Roman, or Moresco—of course not considering magnitude of parts, but general forms and arrangements. Indeed, the remark may be extended beyond the mere plans; for all have, to a certain extent, insulated columns placed equidistant, and crowned with an entablature; and the general effect of many Chinese buildings is altogether Moorish.

Jewish architecture.

Architecture was not likely to flourish among the shepherd tribes of Israel. It is in agricultural and commercial countries, such as Egypt and Greece, that its noblest works are produced, and not among the nomades of Arabia and Palestine. Saul, the first king of Israel, appears to have had no settled place of abode; and the most sacred ceremonies of the Jewish religion were performed at Gilgal, where was the temple of unhewn stones set up by Joshua on taking possession of the promised land, and making a covenant between God and the people, until the building of the temple at Jerusalem in the place rendered holy by Abraham's great sacrifice. Saul himself was confirmed in the kingdom at Gilgal, and there the nation swore allegiance to him with sacrifices to the Almighty; but as yet nothing existed there in which to perform the rites, except the ancient Celtic structure to which we have alluded. Joshua also set up an altar in Mount Ebal, and in long after times a splendid temple was erected in one of the two neighbouring mounts, Ebal or Gerizim, where the Samaritans worshipped. Like his predecessor on the throne, David appears to have been but indifferently lodged till towards the end of his reign, when he is said to have built himself a house; and until the temple was built in the following reign, the ark of the covenant was never in a fixed place;—it was at one time in a private house, at another in captivity among the Philistines; and, indeed, King David expressed his shame that he had a house of cedar, whilst the ark of the Lord still dwelt in a tent. These things, and the fact that Solomon sent to Tyre for workmen, and indeed for an architect also, are, we think, conclusive evidence, that in whatever state architecture was among the Jews from the building of the temple at Jerusalem, it was very low before that time; and from the descriptions we have of that edifice itself in the Bible, it appears to have exhibited a greater degree of barbaric splendour than of classic elegance. From mere description, however, it is impossible to understand an unknown species of building, as many things we shall have occasion to refer to will clearly prove.

Few things have occasioned controversies more amusing, from the singularity of some assumptions, and the absolute futility of them all, than the style and manner in which Solomon's temple was built. Villalpanda, a Spanish Jesuit, appended to a commentary which he wrote on the prophecies of Ezekiel, a long dissertation on the first and second temples of Jerusalem, in which he insists that the theory and practice of permanent architecture commenced with the building of that temple by Solomon—that with it, " the orders," which, he says, are falsely attributed to the Greeks, came into existence—that indeed the design (from a passage in the first book of the Chronicles), perfect in all its details, was given to David, *drawn by the hand of God!* He moreover pretends to show, that the proportions assigned by Vitruvius to the different orders accord exactly with the descriptions given of the temple of Solomon; and accuses Callimachus of usurping the honour of inventing the Corinthian capital, which could not belong to him, as it was of divine origin, and had been executed in the temple at Jerusalem centuries before he was born. Some learned, and in some respects sensible men, have attempted to support this theory; and others have thought it worth while to controvert it, by proving that the architect and the principal workmen were all either Egyptians or Phœnicians, and that consequently the edifice must have been in the Egyptian style. A learned architect of the present day has endeavoured to show that it was in the Greek style, and that its form, proportions, and distribution, were not dissimilar to those of the temple of Ceres at Eleusis. As the Phœnicians, who were principally employed by Solomon, themselves built in the Egyptian manner, we think the probability is great that it was in the Egyptian or Phœnician style, as far as the Jewish ceremonial would permit; and certainly the descriptions of its distribution accord better with that of an Egyptian than of a Grecian temple. The pillars of Jachin and Boaz, which are said to have been set up before the temple, correspond exactly in relative situation with the obelisks in temples at Thebes. Clemens of Alexandria, too, gives a description of an Egyptian temple very much like that of the Jewish; and the palm-leaves, roses, fruits, and flowers, in the latter, are very common in existing specimens of the former, whereas in the Greek remains of early date no such things are to be found. Whether the Jews in after-times possessed a national style of architecture or not, we cannot tell: there is no reason, however, for supposing that they did; for their monotheistic structure at Jerusalem was not repeated in other places, as the temples of the heathen divinities were among the Greeks and Romans, by which they might have acquired a peculiar mode of composition and combination. The non-existence of a national Jewish style of architecture tends also to strengthen our position, that architecture did not originate in the disposition and decoration of buildings for domestic purposes, of which the Jews must, when settled, have made as much use as other nations; and a multiplicity of religious edifices, in the construction of which they might have acquired one, was forbidden by their code.

Pelasgic architecture.

In various parts of Greece and Italy, specimens of rude walling are found of such remote antiquity that they are, as by common consent, referred to the fabulous ages, and, for want of a more distinctive term, are called Cyclopæan. Now it appears, from the concurring evidence and opinions of most antiquaries, that a people who have been called Pelasgi, or sailors, migrated from Asia Minor, or the coast of Syria, at a very early period, and possessed themselves of various countries, some of which were unoccupied, and others inhabited by Celtic tribes. Mr Godfrey Higgins says that the Pelasgi were Canaanites, and being a hardy sea-faring race, they soon subdued the Celtic inhabitants of Delphi in Greece, or of Cumæ in Italy, who, from their first quitting the parent hive, never had occasion for an offensive weapon, except against wild beasts; and that they were the people who settled Carthage, Spain, and Ireland. Bishop Marsh has proved the Pelasgi to be Dorians, Dr Clarke has proved the Etrusci to be Phœnicians, and Gallæus has proved the Dorians to be Phœnicians. Thus, says Mr Higgins, the Pelasgi, the Etrusci, and the Phœnicians, are all proved to be the same. According to Professor Heeren, also, who affixes dates to the various migrations, the Pelasgi were of Asiatic origin. " Their first arrival in the Peloponnesus was under Inachus, about 1800 years B. C.; and according to their own traditions," he says, " they made their first appearance in this quarter as uncultivated savages. They must, however, at an early period, have made some progress towards civilization, since the most ancient states, Argos and Sicyon, owed their origin to them; and to them, perhaps with great probability, are attributed the remains of those most ancient monuments generally termed Cyclopic."[1] He adds, that the Hellenes, a people

[1] *Manual of Ancient History*, p. 119.

[2] The Celtic Druids, c. vi. § 29, p. 259.

History.

of Asiatic origin also, expelled the Pelasgi from almost every part of Greece, about 300 years after their first occupation of it; the latter keeping their footing only in Arcadia and in the land of Dodona, whilst some of them migrated to Italy, and others to Crete and various islands. The arrival of the Egyptian and Phœnician colonies in Greece, Professor Heeren thinks, was between 1600 and 1400 B. C.

The connection of Greece and Italy with each other, and with Egypt and Phœnicia, is thus made evident. The Cyclopæan structures, however, were the works of the rude Pelasgi before that connection took place, except as far as it existed in their having a common origin. They occupied, either simultaneously or consecutively, both Greece and Italy; and this accounts for the sameness of that peculiar and original mode of structure which, we have said, is found in both countries, though no evidence exists of its ever having been practised elsewhere. If, indeed, the things in question were the work of the earlier Celtic inhabitants, a still more remote date must be assigned them than they could derive from the Pelasgi; and this is the opinion of Mr Higgins, supported, he contends, by the suffrages of Dodwell, Clarke, and others, who say that the doorway called the Gate of the Lions, in the Acropolis of Mycenæ, is built exactly like the remains of Stonehenge. The most ancient specimen of Cyclopic walling is found at Tyrinthus, near Mycenæ. It is composed of huge masses of rock roughly hewn and piled up together, with the interstices at the angles filled up by small stones, but without mortar or cement of any kind. The next species is in stones of various sizes also, shaped polygonally, and fitted with nicety one to another, but not laid in courses. Specimens of this are found at Iulis and Delphi, as well as at the places already mentioned, in Greece, and in various parts of Italy, particularly at Cossa, a town of the Volsci. This also was constructed without mortar. The mode of building walls, which took the place of that, is not called Cyclopæan; it is in parallel courses of rectangular stones, of unequal size, but of the same height. This is common in the Phocian cities, and in some parts of Bœotia and Argolis. To that succeeded the mode most common in, and which was chiefly confined to, Attica. It consists of horizontal courses of masonry, not always of the same height, but composed of rectangular stones.

Plate LI. Fig. 14.

Fig. 16.

Grecian architecture.

The oldest existing structure in Greece of regular form is of far superior construction to the Cyclopæan walling, and must be referred to the Egyptian or Phœnician colonists. It is at Mycenæ, and consists of two subterranean chambers, one of which is much larger than the other. The outer and larger one is of circular form, and is entered by a huge doorway at the end of a long avenue of colossal walls, built in nearly parallel courses of rectangular stones, roughly hewn, however, and laid without mortar. Its external effect is that of an excavation, though the structure of the front is evident; and internally it assumes the form of an immense lime-kiln; its vertical section being of a somewhat conical form, under nearly parabolic curves, like a pointed, or what is vulgarly called a Gothic arch. The construction of this edifice was thought to afford clear evidence that the Greeks were acquainted with the properties of the arch; but in the most material point this was destroyed on finding that it consisted of parallel projecting courses of stone in horizontal layers, in the manner called by our workmen battering, or more correctly perhaps corbelling. It proves, however, that its architect understood the principle of the arch in its horizontal position; for Mr Cockerell has discovered, by excavations above it, that the diminishing rings of which the dome is composed are complete in themselves for withstanding outward pressure; the joints of the stones being partly wrought radiating, and partly rendered so by wedges of small stones driven tightly into them behind. The apex is formed, not by a key-stone, for the construction does not admit of such, but by a covering stone, which is merely laid on the course immediately below it. It may be added, that internally the lower projecting angles of the stones are worked off to follow the general outline. Though this is the largest and most perfect, its internal diameter at the base being 48 feet 6 inches, and its height from the floor to the covering stone 45 feet, yet edifices exhibiting similar structure are found in many other places in Greece itself, in Egypt, in Sicily, and in Italy. They all however tend to prove, that the principle of the construction of the vertical arch was unknown at the time of their erection in all those countries; and their erection is as evidently of the most remote antiquity, perhaps of the presumed era of Dædalus, to whom some have assigned many of them, as well as the discovery of so much of the principle of the arch as is exhibited in the arrangement of the horizontal rings or layers in the Mycenæan monument. Neither could the mechanical powers have been unknown to their constructors. In the edifice which we have described, and which is thought by some to be the Treasury of Atreus, or the Tomb of his son Agamemnon, mentioned by Pausanias as existing among the ruins of Mycenæ in his time, the inner lintel of the doorway is 27 feet in length, 16 feet deep, and nearly 4 feet thick, weighing, it is computed, upwards of 130 tons; and the lintel of the Gate of the Lions in the Acropolis of the same city, is, from its immense magnitude, also strongly illustrative of the great mechanical skill of the people of those times. As the Treasury of Atreus at present exists, it exhibits nothing like an attempt at decoration, except that the doorway is, on the outside, sunk in two faces all round, as if to harmonize with some architectural composition; and the interior of the edifice may be supposed to have been lined, probably with plates of metal, like the tower of Acrisius, as bronze nails for attaching them to the vault still remain. Some sculptured fragments of marble which have been found among the ruins of the fallen parts and the rubbish which chokes up the entrance, together with indications on the external front of the edifice that it was cased, have led to an ingenious attempt at restoration, upon the supposition that the fragments were parts of a frontispiece. The fact that such frontispieces were sometimes carved, and sometimes constructed, in connection with the entrances of excavated tombs and other *spea* in Egypt and Nubia, gives a degree of probability to the idea that it would not otherwise have; for the fragments do not resemble the earliest existing specimens of Greek architectural forms; though indeed these latter may be traced to Persepolis, and Ibrim in Nubia, according to several ingenious antiquaries and architects. In curious accordance with this Mycenæan structure is the ancient monument at New Grange, near Drogheda, in Ireland. Ruder in every respect than the former, in form, construction, and mode of access, it bears such a striking similarity to it, that it is almost impossible to be supposed the effect of mere chance. The opinion of Mr Godfrey Higgins, that the Pelasgi, who peopled many of the countries on the shores of the Mediterranean Sea, peopled Ireland also, appears to be supported by this coincidence between the so-called Treasury of Atreus, or Tomb of Agamemnon, in the Peloponnesus, and the monument at New Grange in Ireland.

Plate LI. Fig. 10.

We know of no columnar edifice in Greece, or elsewhere in the Grecian style, of earlier date than the ruined temple at Corinth, which is in the plainest and sim-

History.

plest form of what has been called the Doric Order, though it would be more correctly designated the Doric Style; for the term Order is objectionable, because it supposes rules and limitations to what in its best times was subjected to neither. As, however, it is the term best understood, we shall not hesitate to continue it. It is difficult, if not impossible, to ascertain where and in what manner the Doric order originated. The example we have referred to, though the earliest, does not differ in its leading features and characteristics from the more perfect specimens of later date; and it bears no direct and easy analogy to any species of columnar arrangement of other countries and earlier times. The story of Vitruvius, even supposing it rational, does not coincide with the Greek style of Doric at all, but, if with any thing, with the Roman examples of it, which at the best are mean and inelegant deteriorations of the simple and beautiful original. This author says that "Dorus, the son of Hellenus and of the nymph Orseis, king of Achaia and of all the Peloponnesus, having formerly built a temple to Juno in the ancient city of Argos, this temple was found by chance to be in that manner which we call Doric."[1] In another place he deduces the arrangements of this same order from those of a primitive log-hut in the first place, through all the refinements of carpentry, leaving nothing to chance, but settling with the utmost precision what, in the latter, suggested the various parts of the former. Chance in one case, and experience in another, however, are not enough for this author; but he also tells us that the Doric column was modelled by the Grecian colonists in Asia Minor, on the proportions of the male human figure, and was made six diameters in height, because a man was found to be six times the length of his foot; and that eventual improvements occasioned the column to be made one diameter more, or seven instead of six. "Thus the Doric column was first adapted to edifices, having the proportions, strength, and beauty of the body of a man!" The earliest examples of this order, however, are those which least agree with the primitive forms and proportions of Vitruvius; the columns at Corinth hardly exceed four diameters in height, while in later examples they gradually extend, till, in the temple of Minerva on the promontory of Sunium, the columns are nearly six diameters, being one of the tallest specimens of pure Greek origin ever executed. If the trunks of trees used in the structure of tents suggested the first idea of columns, and of the Doric in particular, as many contend, how is it that the earliest specimens discovered are the most massive? For the merest saplings would have formed the wooden proto-columns, and necessarily, when imitated in stone, they would not have been made more bulky than the less tenacious nature of the material required; much less would the slender wooden architrave have been magnified into the ponderous entablature of the primitive permanent architectural structures of all nations. In the construction of edifices with the trunks of trees, and timber generally, then, we do not find the origin of Doric architecture. If we have recourse to Egypt, the mother of the arts and sciences, we shall indeed find many things even in the more ancient structures which *may* have furnished an idea of the Doric arrangements to the fertile imagination of a Greek. The later works of that country cannot be trusted for originality, as they may themselves have been influenced by Greek examples; but we hardly dare assert that the Doric order was suggested by any thing in Egyptian architecture, though in making such assertion we should be supported by the opinions of many competent judges. The temple at Amada in Nubia can hardly be positively assumed as an example of the *proto-Doric*, though it may of the *proto-columnar*. Nevertheless, the example is striking, as it certainly possesses the Doric character. The broad square abacus, and the cylindrical or even conoidal tendency of the shaft, marked as it is, as if for fluting, with the plain, simple, and massive epistyle or architrave superimposed, are all in accordance with the Hellenic columnar ordinance; still there is nothing to connect that rude model with the positive and somewhat formally arranged example at Corinth with which we began. It must be remembered, however, that two connecting links between Egyptian and Greek architecture are lost; Lower Egypt, with its splendid capital Memphis, and Phœnicia; through which latter the learning and taste of the inhabitants of the former country appear to have taken their course; but of neither of these do we possess architectural remains that bear on the subject in question. In the Pharaonic structures of Thebes we find both the tumescent and the cylindrical columns; and an amalgamation and modification of the two would easily produce the Doric column, or something very much like it, which may have been executed in those places, and so transferred to Greece. Of the triglyphs, the most distinguishing part of the Doric entablature, there are many indications in the early works of Upper Egypt; and in the structures of the Ptolemies they are still more evident; though it may be objected that, in these, those indications were borrowed from the Greeks after the Macedonian conquest. But it must be borne in mind that the Egyptian nation did not change its character, religion, or usages by the change of its governors; and the Egyptians were, through the whole period of their existence as a nation, an originating and not an imitative people; whereas the Greeks seized on a beauty wherever they found one, and made it their own by improving it. The forms and arrangement, too, of many of the Greek mouldings, and the manner of carving to enrich them, are common in the earliest ornate works of the Egyptians; and such things are as strong evidence of community of origin, as the existence of similar words having the same meaning in different languages is of theirs. We may be asked, why the Greeks cannot be allowed to have originated that beautiful style of architecture which they brought to the perfection it displays in their works? To which we think it a sufficient answer, that it would be against the common course of events if it were so. In Egypt we can trace a progress from the ruder to the more advanced, and, with trifling discrepancies, to the most perfect; but in Greece, the earliest specimen of columnar architecture that presents itself displays almost all the qualities and perfections which are found in works of periods when learning and civility were at their acme in that country. We cannot find in Greece a stepping-stone from the Celtic or Pelasgic Gate of the Lions of Mycenæ, to the Doric columns at Corinth, and hardly to the Fane of Minerva in the Acropolis of Athens; and have therefore to seek the gradations among the people with whom we have seen they were connected, and whose country furnishes them in a great measure, if not entirely. Differences in climate and in political constitution, as well as in forms of religion, account sufficiently for the differences between the arrangements of the religious structures of the Greeks and those of Egypt. At the present day we find, that though they may be built in the same style, and for the worship of the same divinity, there is a wide difference between a church in Italy and a church in England, and a still greater between a church in the former country and

History. Plate LI.

[1] Vitruvius, lib. i. cap. i.

one in Scotland. The model, however, of the Greek temple is found in many places in Egypt, generally placed as a chapel or ædicula, subsidiary to, and in connection with, the larger structures, as well as in the earlier Nubian temples themselves.

None other than the Doric style or order was used in Greece till after the Macedonian conquest, about which period that beautiful and graceful variety called the Ionic was brought into use. It is as difficult to determine its origin as that of the Doric. Vitruvius says that the Ionian colonists, on building a temple to Diana, wished to find some new manner that was beautiful; and by the method which they had pursued with the Doric, proportioning the column after a man, they gave to this the delicacy of the female figure; in the first place by making the diameter of the column one eighth of its height, then by putting a base to it in twisted cords, like the sandals of a woman, and forming the capital with volutes, like the hair which hangs on both sides of her face. To crown all, he says that they channelled or fluted the column, to resemble the folds of female garments, by which it would appear that Vitruvius did not know that the Greeks never executed the Doric order without fluting the columns. "Thus," he goes on to say, "they invented these two species of columns, imitating in the one the naked simplicity and dignity of a man, and in the other the delicacy and the ornaments of a woman." It can hardly be doubted that the voluted or Ionic order did originate in Ionia, at least we know of no earlier examples of it than those which exist there; and it does not appear to have been known to the European Greeks, and certainly was not practised by them, till after the period we have indicated. It probably took its rise from some peculiarities in Persian architecture; though many believe that the Ionic order had a much earlier origin, deriving it from Egypt, where, it is true, many indications are found of its volutes in the spiral enrichments of capitals; but it must be observed that they are in edifices now ascertained to be of the age of the Ptolemies, and consequently later than the structures which exhibit the voluted order in Ionia and its islands. We think, too, that many persons are influenced in assigning a higher degree of antiquity to this style than facts will bear out, by their respect for the authority of Vitruvius; though Mr Gwilt (his latest translator into English) confesses that "upon his authority in matters of historical research not much reliance is to be placed."[1] We are willing to admit that much may be adduced in support of the opinion, that this style was known and used in Greece even before the age of Pericles; specimens of it having been found in connection with sculpture, certainly less perfect, and therefore presumed to be of earlier date, than the works of Phidias and his pupils and compeers.

It is no less difficult to determine the origin of what is called the Corinthian order. The not inelegant traditionary tale by Vitruvius of the invention of its capital, is the only *reason* of the name it bears. His account of the origin of this third species of columnar composition is more summary, and not less absurd, than that of the preceding. He says that it was arranged "to represent the delicacy of a young girl whose age renders her figure more pleasing and more susceptible of ornaments which may enhance her natural beauty." With much more reason might the Doric be called the Corinthian order; for, as we have stated, at Corinth there exists the oldest example of that style; whereas there is nothing, either in ruins or authentic record, to prove that the latter was ever known in that city. Columns with foliated capitals are not of very early date in Greece; earlier examples exist in Asia Minor, and foliage adorns the capitals of columns in some of the Pharaonic monuments of Egypt; not arranged, indeed, as in the later Corinthian capital, which by possibility may have been the result of some such accident as Vitruvius relates of Callimachus and the basket on the grave of the Corinthian virgin. The interior of the temple of Apollo Didymæus at Miletus in Ionia exhibits the earliest example of the acanthus leaf arranged round the drum of a capital in a single row, surmounted by the favourite honeysuckle; but that edifice was constructed about a century before Callimachus is understood to have lived. The only perfect columnar example in Greece itself of this species of foliated capital is of later date than, and is a great improvement on, that of Miletus; it is the beautiful little structure called the Choragic monument of Lysicrates at Athens. Specimens are less uncommon in Greece of square or antæ capitals, enriched with foliage, than of circular or columnar capitals; but they are almost invariably found to have belonged to the interior of buildings, and not to have been used externally. In considering Greek architecture, it is necessary to bear in mind that it ceases almost immediately after the subjection of Greece to the Roman power; for there are many edifices in that country in the style of columnar arrangement of which we are now speaking besides those referred to, but they belong to Roman and not to Greek architecture. The earliest of them perhaps, and certainly the least influenced by Roman taste, is the structure called the Tower of the Winds, or of Andronicus Cyrrhestes, at Athens. A spurious example of Greek Doric, evidently executed under the Roman domination, may be referred to here; it is that of the Agora, or Doric portico, as it is sometimes distinguished, in the same city.

Plate LVI Figs. 1, 2, & 3.

Besides the three species of columnar arrangement we have enumerated, the Greeks employed another in which statues of women occupied the place of columns. The *reason* of this too Vitruvius furnishes in a story which is, as usual, totally unsupported by history or analogy; but the consequence of it is, that such figures are called Caryatides; and the arrangement has been called by some the Caryatic order. The use of representations of the human and other figures with or instead of columns is, however, common in the structures of Egypt and India; and to the former the Greeks were doubtless indebted for the idea, though they appear to have restricted its application to human female figures. Mr Gwilt infers, from various facts connected with the worship of Diana Caryatis, "that the statues called Caryatides were originally applied to or used about the temples of Diana; and instead of representing captives or persons in a state of ignominy (as the Vitruvian story goes), were in fact nothing more than the figures of the virgins who celebrated the worship of that goddess."[2]

The only architectural works of the Greeks that remain to us of any consequence, besides temples, propylæa, and Choragic monuments, are theatres; but these latter do not retain any thing connected with architectural decoration to make them interesting, except to the architect and antiquary. They are generally situated on the side of a hill, and were rather excavated or carved out in the earth or rock, than built; except the proscenium and parascenium, which being at the lower part, in front, and requiring elevation, must of necessity be built; but very little of the constructed portions in any case exists. It does not appear that the theatres afforded any provision for sheltering the spectators, or indeed the ac-

[2] *Ibid.* p. 57.

History

tors, from rain, except perhaps a covered cyrtostylar colonnade within the upper boundary wall, which, even when it existed, was of necessity very narrow and small for so large a number of people as were generally assembled; for the theatres were calculated to hold from five to fifteen and even twenty thousand persons. This, to say the least of it, must have subjected the public to great inconveniences, even in so fine a climate as that of Greece; for they were unsheltered from the sun at all times, and effectually debarred from a favourite amusement in wet weather.

No remains exist of the domestic structures of the Greeks; and we are too well aware, from the example of others, of the futility of following mere descriptions on the subject, to attempt it here; especially as the most explicit are those of Vitruvius, whom we know to have been ignorant of the arrangement of Greek temples, by those of them which exist, and may therefore reasonably suspect of ignorance with regard to things of which we have no remains. It may be taken for granted that the houses of the Greeks were less extensive than those of the Romans, as they were a poorer and less luxurious people; and we shall be able to determine those of the latter nation with great exactitude, from the actual remains of Roman towns and country mansions. The exquisite beauty of form and decoration which pervades every article of Greek origin, whether coins, medallions, vases, implements of war or husbandry, or even the meanest article of domestic or personal use of which we have specimens or representations, is evidence of the fine taste with which the mansions of the Greeks were furnished. However, ignorance of the use of the arch, inferior carpentry, the absence of glass, and ignorance of the use of chimneys, were disadvantages which the Greeks laboured under in the construction and convenient arrangement of their houses, that no degree of taste and elegance could completely countervail.

In the construction of their edifices, the Greeks seldom, if ever, had recourse to foreign materials; the stone used in their temples being almost invariably from the nearest convenient quarries, which supplied it of sufficiently good quality. The structures of Athens are built of marble from the quarries of Pentelicus, and those of Agrigentum of a fossil conglomerate which the place itself furnishes.

Invention of the arch.

We have taken it for granted that the Greeks were ignorant of the properties of the arch, having too high an opinion of their good sense to think that they could be acquainted with so useful and admirable an expedient, and never use it; and no instance of its adaptation occurs in the construction of Greek edifices before the connection of Greece with Rome took place. Whether its invention should be referred to Italy or not is another question. If the great sewer at Rome called the Cloaca Maxima was constructed in the time of Tarquinius Priscus, it must be conceded that the properties of the arch were known and the arch applied in that country at an earlier period than we know the principle to have been understood and applied elsewhere; for neither Egypt nor Greece, nor any of the Grecian colonies, can furnish evidence that it was known to either Egyptians or Grecians till a long time after the period referred to, and when it may have been communicated from Italy. But it is contended that the Cloaca Maxima, as it now exists, is a work of much more recent date, and that it may have succeeded the sewer constructed by the first Tarquinius, who was moreover himself a Greek. If the first part of the objection be correct, the evidence in favour of Italy is destroyed, as far as that work is concerned; the second is fallacious, because it is not necessary that the monarch should have brought the knowledge with him; though indeed he might have acquired it in Etruria, or it might have existed in Rome before his arrival there. Most writers on the subject are of opinion that the principle of the arch was not known, in Europe at least, nor to the nations of Western Asia and Africa, till after the Macedonian conquest, about which time it may have been invented, or acquired from some of the eastern nations who were visited by the conquerors. To these suggestions the objections hold that the arch was not applied in Egypt in the architectural works which remain of the Ptolemies, nor is it found in the Persian and Indian monuments which date beyond that period. The author of the *Munimenta Antiqua*, after a comprehensive review of all the authorities and examples on the subject, gives it as his own opinion that "Sicily was the country where this noble kind of ornament first appeared, and that Archimedes was the inventor of it."[1] The evidence appears, we think, generally stronger in favour of its Italian origin; but to whomsoever the invention may be attributed, and whensoever it was made, the Romans were the first to make extensive practical use of it; and by its means they succeeded in doing what their predecessors in civilization had never effected. It enabled them to carry secure and permanent roads across wide and rapid rivers, and to make a comparatively frail and fragile material, such as brick, more extensively useful than the finest marbles were in the hands of the Greeks without that principle. To the Greeks, however, the Romans were indebted for their knowledge of the more polished forms of columnar architecture; for, before the conquest of Greece, the structures of Rome appear to have been rude and inelegant. The few specimens of architecture which exist of date anterior to that period evidently resemble the works of the ancient Etrurians, who, though they had made considerable advances on the architecture of their Pelasgic ancestors, were far inferior in taste and refinement to the Greeks; yet it is to that people we are inclined to attribute the invention of the arch, from whom the Romans acquired their knowledge of its use, and that degree of civilization which they possessed before the epoch referred to. It may be presumed that the Etrurians had also originated the style of columnar architecture which Vitruvius describes and calls Tuscan; but as no example of it exists, at least nothing that answers his description of it, we cannot tell positively what it really was; for, as we have before remarked, descriptions without a model, of architecture particularly, are quite unintelligible, as far as understanding a new style goes. Whatever then was the style of architecture in Rome before the conquest of Greece, it was either exploded by the superior merit and beauty of what the Romans found in that country, or combined with it, though frequently the combination tended to destroy the beauty of both. In the porticoes of the temple of Antoninus and Faustina, and of the Pantheon, at Rome, the chaste simplicity of a Greek columnar composition is preserved, and in the magnificent dome of the latter edifice, and in the long extended aqueduct, it is fully equalled. But the triumphal arch of the Romans, a hybrid composed of columns and arches, is devoid alike of simplicity and harmony, indeed of every quality which constitutes beauty in architecture.

Roman architecture.

In the transference of Greek columnar architecture to Rome, a great change was effected, independently of those combinations. The less refined taste of the Romans

[1] *Munim. Antiq.* by Edward King, Esq. F.R.S. and S.A. vol. ii. p. 268.

could not appreciate the simple grandeur and dignified beauty of the Doric, as it existed in Greece. They appear to have moulded it on what we suppose their own Tuscan to have been; and the result was the mean and characterless ordinance exemplified in the lowest story of the theatre of Marcellus at Rome, and in the temple at Cora, between 30 and 40 miles south of that city. Not less inferior to the Athenian examples of the Ionic order, than the Doric of Cora is to the Doric of Athens, are the mean and tasteless deteriorations of them in the Roman temples of Manly Fortune and Concord. It was different, however, with the foliated Corinthian, which became to the Romans what the Doric had been to the Greeks—their national style. But though they borrowed the style, they did not copy the Greek examples. In Rome the Corinthian order assumed a new and not less beautiful form and character, and was varied to a wonderful extent, but without losing its original and distinctive features. The example of the temple of Vesta at Tivoli differs from that of the temple of Jupiter Stator in Rome, as much as the latter does from the ordinance of the choragic monument of Lysicrates at Athens; and all three are among the most beautiful examples of the Corinthian order in existence—if indeed they are not pre-eminently so—and yet they do not possess a single proportion in common. It must be confessed, moreover, that if the Romans had not good taste enough to admire the Doric and Ionic models of Greece, they had too much to be fond of their own, for they seldom used them. Both at home and abroad, in all their conquests and colonies, wherever they built, they employed the Corinthian order. Corinthian edifices were raised in Iberia and in Gaul, in Istria and in Greece, in Syria and in Egypt; and to the present day Nismes,[1] Pola, Athens, Palmyra, and the banks of the Nile, alike attest the fondness of the Romans for that peculiar style. We cannot agree with the generally received opinion, that Greek architects were employed by the Romans after the connection between the two countries took place; for the difference between the Greek and Roman styles of architecture is not merely in the preference given to one over another peculiar mode of columnar arrangement and composition, but a different taste pervades even the details: though the mouldings are the same, they differ more in spirit and character than do those of Greece and Egypt, which certainly would not have been the case if Roman architecture had been the work of Greek architects. Indeed, were it not for historical evidence, which cannot absolutely be refuted, an examination and comparison of the architectural monuments of the two countries would lead an architect to the conclusion, that the Corinthian order had its origin in Italy, and that the almost solitary perfect example of it in Greece was the result of an accidental communication with that country, modified by Greek taste; or that the foliated style was common to both, without either being indebted to the other for it. The Romans conquered Egypt as well as Greece, but we do not find that they adopted any of the peculiarities of Egyptian architecture. They carried away indeed the obelisks and many of the sculptures of Egypt, as trophies of their conquests or as ornaments of their city; but they neither made obelisks nor constructed temples to Egyptian divinities in the Egyptian style. If, however, Greek architects were employed by the Romans, they must have made their taste and mode of design conform to those of their conquerors much more readily than we can imagine they would as the civilized slaves of barbarian masters; and it is too clear to be disputed, that the Roman architecture is a style essentially distinct from the Greek. This is elucidated by the fact that many of the minor works of sculpture in connection with architecture, such as candelabra, vases, and various articles of household furniture discovered at the villa of Adrian, near Tivoli, and at Herculaneum and Pompeii, are fashioned and ornamented in the Greek style, while others are as decidedly Roman in those particulars; rendering it evident that such things were either imported from Greece, or that Greek artists and artisans were employed in Italy, who retained their own national taste and modes of design. It is probable, nevertheless, that both the architects and the artists, natives of Rome, qualified their own less elegant productions by reference to Greek models; but that the Romans derived their architecture entirely from the Greeks, may certainly be disputed.

Half the extent and magnificence of the architectural works of the Romans is attributable to their knowledge and use of the arch, which enabled them, as we have already intimated, to make small parallelopipedons of burnt earth more extensively applicable to useful purposes than any other material could be, from the greater cost of providing and preparing it; whereas brick can, in almost every place, be made on the spot in which it is wanted. There is a very false notion abroad as to the richness of the materials used for building in Rome, induced by the inflated accounts of travellers and poets, who attempt to disguise their ignorance, while they display it by filling Rome with what it never contained—marble temples, palaces, and baths. The truth is, that Rome was built, not of marble, nor even of stone, but of brick; for in comparison to the quantity of brick, it may be safely asserted that there is more stone in London than there was in imperial Rome. Almost all the structures of the Romans indeed were of brick—their aqueducts, their palaces, their villas, their baths, and their temples. Of the present remains, it is only a few columns and their entablatures that are of marble or granite, and two or three buildings of Travertine stone;—all the rest are brick. The Colosseum, the Mausoleum of Adrian, the Tunnel Sewer, the Temple of Manly Fortune, and the ancient bridges on the Tiber, are of Travertine stone; the remaining columns of the more splendid temples, the internal columns and their accessories of the Pantheon, the exterior of the imperial arches, and the cenotaphial columns of Trajan and of Antonine, are of marble: but the Imperial Mount of the Palatine, which holds the ruins of the Palace of the Cæsars, is but one mass of brick; the Pantheon, except its portico and internal columns, &c., is of brick; the Temples of Peace, of Venus and Rome, and of Minerva Medica, are of brick; and so, for the most part, were the walls of others, though they may have been faced with marble or freestone. The Baths of Titus, of Caracalla, and of Diocletian, are of brick; the city walls are of brick; so are the extensive remains of the splendid villa of Adrian, and those of

[1] Bordeaux *did*. A century and a half ago there existed at Bordeaux very considerable remains of a most interesting Roman edifice, of which no authentic record is preserved but a slight sketch by Perrault, the architect of the great front of the Louvre, who delineated it a few years before its destruction by the government, and who termed it one of the most magnificent and most entire of the Roman monuments then remaining in France. The editor of the new edition of Stuart's Athens, speaking of this, says, "on this occasion the reflection presents itself, that while the Turks are reprobated for appropriating the columns of ancient Athens, in their haste to raise a wall to defend their town from the predatory Albanians, here, in the vaunted age of Louis XIV. (in his kingdom and under his government, may be added) the finest production of ancient architecture in France was more recklessly demolished to make place for the fortifications of Bordeaux, deliberately constructed by Vauban; and no architect, either of the city or government, has preserved for posterity the details of so noble a monument." (*Antiquities of Athens*, new edition, vol. iii. p. 120.)

History.

the villa of Mecænas at Tivoli; the palaces of the Roman emperors and patricians at Baiæ and in other parts of Italy; and so, it may be said, are the remains of Herculaneum and Pompeii, for the houses in those cities are generally built of alternate double courses of brick, and courses of stone or lava. In most cases, at Rome and in the provinces, stucco formed the surface which received the decorations. From the above enumeration, it will appear how much more variously the Romans built than any of their predecessors in civilization did. In Egypt we find no indications of edifices of real utility or convenience, nothing but temples and tombs,—and in Greece there is but a small addition to this list; but in Rome are found specimens of almost every variety of structure that men in civilized communities require. Much of this also may be attributed to the knowledge they possessed of the properties of the arch, which may be considered among the most admirable and useful discoveries ever made in the practical applications of mechanical science. It entered into the composition of every structure, and made the rudest and cheapest material of more real value than the most costly. It not only superseded the use of long stone beams, but was constantly used in places where indeed joists of wood would have been much more convenient, giving support to the opinion that even the Romans were not skilled in the application of timber to their edifices; though, on the contrary, it is difficult to understand how Rome could become subject to such a dreadful conflagration as that which occurred in the reign of Nero, if timber had not been employed in the ordinary houses of the city to a much greater extent than would appear from existing remains. The domestic structures of Herculaneum and Pompeii were evidently never very susceptible of fire, from the small quantity of timber required in their construction; and discoveries which are made from time to time, of portions of the ordinary houses of ancient Rome, under the pavements of the modern city, evince that they were very similar to them in almost every particular. The infrequency of stairs, and the meanness of those which exist leading to upper apartments in the houses of those cities, induce the belief that the Romans seldom built above the ground story, and that their skill in carpentry was not very great; otherwise they would more frequently have had recourse to so easy and convenient a mode of extending room as upper stories offer. There are, however, other things which tend to prove that carpentry was well understood by the Romans; and the most remarkable is the bridge that Trajan built over the Danube, the piers of which are said by Dion Cassius to have been 150 feet high and 170 feet apart. Now, whether the bridge itself consisted of a wooden platform, as there is much reason to believe, or was of stone arches, as the historian intimates, the skill which constructed centring for the latter, or laid the platform from pier to pier in the former case, of that immense extent, was amazing; nevertheless, such skill in carpentry is not evinced by the remains of the civic and domestic structures of the Romans, in which arching in all its varieties was used where carpentry would have been better. Of their joinery we know nothing; but it does not appear, from the last-quoted mode of ascertaining such things, to have been much practised by them—mosaic pavements supplying the place of flooring, and stucco that of wainscoting: the luxury of windows being unknown, their fittings were not required; and doors, it would appear, were uncommon, except externally—the internal doorways being most probably covered with something equivalent to the quilted leather mats suspended from the lintel, which are used instead of swinging doors at the entrances of the churches in Italy at the present time. Although the Romans did not use marble to the extent that has been supposed, yet they were extremely luxurious in the use of costly stones. Marbles of every variety, and from all parts, were used in Rome; and columns were made of Egyptian and other granites, and of porphyry. In Greece, and the Grecian colonies which were conquered by Rome, the edifices of the Romans might be distinguished by the foreign marbles used in them, if the style of their execution were not sufficient otherwise to determine them.

The mingling of columnar and arcaded arrangements in the same composition appears to have been the grand cause of the deterioration of Roman architecture. It occasioned unequal and inordinately distended intercolumniations and broken entablatures: these a vitiated taste repeated, where the necessity that had first occasioned them did not exist; and harmony and simplicity being thus destroyed, the practice went on deteriorating until it was made to produce such monstrous combinations as the Palace of Diocletian at Spalatro, and the Temple of Pallas, or ruins of the Forum of Nerva in Rome, present. It was indeed a fall from the grandeur, harmony, and noble simplicity of the interior of the Pantheon in its pristine state, to the hall or xystum of the baths of Diocletian, which now exists as the church of Santa Maria degli Angeli, with its straggling columns and broken and imperfect entablature; or from the temple of Jupiter Stator to that of Concord or the arch of Septimius Severus.

Architecture as a fine art was already extinct among the Romans when the seat of empire was transferred to Constantinople; so that, however great were the extent and splendour of the edifices, we cannot suppose them to have possessed any of those qualities which give to the Parthenon at Athens, and to the interior of the Pantheon at Rome, the charm they possess; unless the Greeks had recourse to the monuments of their own country, and used them as founts from which to draw matter for the composition of the edifices of their new capital. This, indeed, is possible, for there appears to have been, even in Rome, at and after the time of Constantine, a recurrence to the ancient simplicity, though, truly, without any of that beauty and elegance of form in the details, and of proportion in the general arrangement, which constitute half the merit of works of architecture. The change of religion which took place under Constantine led to the destruction or destitution of many of the noblest structures in Rome. The ancient Christian basilicas are for the most part constructed of the ruins of the more ancient Pagan temples, baths, and mausoleums; and in them a much greater degree of simplicity, and consequent beauty, pervades the columnar arrangements than existed perhaps in some of the previous combinations of the same materials. Frequently, however, the collocation of various parts was most unapt; and gross inconsistencies were recurred to, to get rid of the difficulty of combining discordant fragments. Sometimes it was necessary to make up with new, what was wanting of old materials, whose forms were rudely imitated.

Gothic or Pointed architecture.

In those countries which received the Christian religion from Rome, but which did not contain mines of architectural material in temples, amphitheatres, and palaces, as Italy did, and indeed in the other parts of Italy itself which did not contain them as Rome did, churches were constructed in imitation of those of the metropolis of the Christian world. These, being the work of a semi-barbarous and unpolished people, were of necessity rude and clumsy. Hence arose the Gothic architecture of the middle ages, and not from any previously existing style of architecture among the northern nations who overran Italy and subverted the Roman power. The rude Celtic

monuments were the only specimens of architecture they possessed, and the performance of their unhallowed rites appears to have been long transferred even from them to the groves, or it may be that the stone circles and temples themselves were called groves. This, however, is of but little consequence to our purpose. The fact is indisputable, that nothing existed among those nations that could have given rise to the rude style of architecture referred to, which was indeed introduced to them by the Christian religion in the manner we have stated. It will be found in what are called the Saxon and Norman styles of this country, and to a greater or less extent in all the countries of Europe in which the Romans had been masters, and particularly in those which adhered to the Roman communion in the great division of the churches. The general forms and modes of arrangement peculiar to Roman architecture may be traced throughout; in some specimens they are more, and in others less obvious, but the leading features are the same. This is more evident in Italy than elsewhere. In the early Roman basilicas and churches, some of which are of the Constantinian age, and which were constructed with the matter and in the manner related, the first divergencies occur; in those which are later they are still greater, and distance of time and place appears still to have increased them, till what may be called a new style was formed, having peculiarities of its own, but yet more clearly deducible from its origin than Roman is from Greek or Greek from Egyptian. As might be expected, this style was not the same in all the countries which practised it; it was derived, in them all, from the same source as we have shown, but was materially influenced by the habits, manners, and state of civilization in which the various nations were, and much too by their means of communication with Rome. This, with strict propriety, may be called Gothic architecture, as it was partly induced by the Gothic invasions of Italy, and was most generally practised by the nations to whom that term may with equal propriety be applied. It arose in the fourth century, and was subverted in the twelfth by the invention or introduction of the pointed arch, which marks a new era, and was destined to give birth to a new style in architecture. Where, when, and with whom the pointed form originated, has been more discussed and disputed than the discovery of the properties of the arch itself. Some have contended that it was suggested by the intersections of semicircular arches, as they were employed in ornamenting the fronts of edifices in the preceding style; some, that groined arches of the same form gave the idea; others have referred it to the interlacing of the branches of trees when planted in parallel rows,—to an imitation of wicker-work,—to a figure used on conventual seals,—to the principle of the pyramid,—to Noah's Ark,—to chance. Its invention has been accorded to almost every nation, civilized and uncivilized. It has been claimed by Germans for Germany, by Frenchmen for France, by Scotsmen for Scotland, and by Englishmen for England. Italians have not directly laid claim to the honour for themselves, but it has been given them by others. Such a mass of conflicting opinions, almost all supported by some show of reason, and more or less by evidence, may be called a proof of the impossibility of determining the question, and therefore we shall not attempt it. There is one striking fact, however, which has been too much overlooked by many of the theorists in the discussion of the question; it is, that the pointed arch made its appearance almost at the same moment of time in all the civilized countries of Europe. This is proved by the controversies of those who, more patriotically than philosophically, claim its invention for their respective nations; for none of them can produce genuine specimens of it before a certain period, to which they can all reach. Now, if it had been invented in any of the European nations, that one would certainly have been able to show specimens of it of a date considerably anterior to *some* of the others; for though it might by chance have been soon communicated to any one of them, the improbability is great that it would immediately have reached them all, and have been at once adopted by all, to the subversion of their previously practised forms of construction. The infrequent and imperfect modes of communication between the different countries of Europe at the period referred to, furnish another reason why it is not probable that a discovery of the kind should travel rapidly from one to another. Considering these things, and particularly the fact of the almost simultaneous introduction of the pointed arch to the various nations of Europe, as it appears by their monuments immediately after the first crusade, in which they all bore a part, connected with existing evidence that it was commonly used in the East at and anterior to that period, it seems to be the most rational theory, that a knowledge of it was acquired by the crusaders in the Holy Land, and brought home to their respective countries by them. This, indeed, is the opinion of many of those who have written on the subject; and without contending that the evidence in its favour is quite conclusive, we think it more satisfactory than any other. In Europe there are found rude approaches to the pointed form in some of the earlier Gothic structures; but we believe it may be safely asserted, that nothing can be indicated of a date beyond that of the first crusade, approaching the simple but perfect lancet arch, which, it is not denied, came into use immediately after that period; whereas tolerably well authenticated examples of it are found in the East, of sufficient antiquity to induce the opinion that it was at that time imported from thence. It is, moreover, indisputable that the Saracenic or Mahometan nations do use, and have used, the pointed arch; but they were never known to adopt any European custom or invention of any kind till very lately How then can they be supposed to have availed themselves so readily as they must have done, if it be of European origin, of so unlikely a thing to attract a Moslem's attention, as the peculiar form and structure of an arch? and when and where in Europe had they an opportunity of contemplating it until long after it is known to have been in common use among them? With what nation of the East, and in what manner, the pointed arch originated, are points equally difficult to solve. We have not been able to discover that the properties of the arch were known to the Egyptians or to the Greeks, and there is no evidence to show that they were known to the Persians or to the Indians of ancient times; but structures are found in the countries of those nations in which chambers are domed, and apertures headed in the form of a pointed arch, produced, however, by gathering or corbelling over, and not by arched structure. It is not improbable, therefore, that such things being before the eyes of men, when the properties of the arch became known that form would be repeated upon it, and the result would be the lancet arch,—the prototype, the germ of the style. The pointed arch, on its introduction into Europe, does not appear to have been accompanied by its ordinary accessories in after-time; its light clustered pillars—its mullions, foliations or featherings, and graceful tracery—these resulted from its adoption: so that whether the arch itself was invented in Europe, or imported from the East, to the European nations must be assigned the credit of educing the beautiful style of architecture whose distinguishing feature it is.

It may be doubted whether Venice was not the parent of the style, for very early specimens of the pointed arch

History. are certainly found there, in private houses as well as in the basilica of St Mark. In the former they are generally of the ogee or contrasted form, in windows formed by columns or mullions, with, in certain places, approaches to foliations and tracery; and in the basilica the lancet arch is not uncommon. The commercial connection of that city with the eastern nations may easily account for its presence there, even before the first crusade; and Venice is known to have been one of the thoroughfares from the other parts of Europe to the Holy Land. But the peculiar mode of arrangement in the Venetian style does not appear to have been adopted north of the Alps; so that, however original it may be, it can hardly be considered the progenitrix of the school, or the model on which it was formed.

Before proceeding further with this subject, it is necessary to determine by what name to call the style whose progress we have yet to contemplate. There would be no greater propriety in calling it Saracenic because its distinctive feature originated in the East, even if that point were conceded, than in calling all architectural combinations which derive their character from the use of columns in them by the name of the nation in whose works we find columns first used, and from whom the idea of them may have been acquired. Neither can it with any degree of fitness be called Gothic: that term, we have seen, applies to the style that preceded it, and was first given to the pointed-arch style opprobriously, during the offuscation of good taste that succeeded its subversion. In Italy it had never taken root, as in the countries north of the Alps—the ancient Roman monuments having continued to influence the national architecture, it would appear, throughout the middle ages; for the ecclesiastical structures of that country, though rude, were never so rude as they were in other places, and a better style had so far formed itself before the introduction of the pointed arch, that it was hardly received there. Indeed, whatever edifices of merit Italy possesses in its manner, are, with hardly an exception, by German architects, few Italians having ever qualified themselves to practise it. When, therefore, what has been called "the revival of architecture" took place in the fifteenth century, under Brunelleschi and his successors, the rude structures of their own country, the precursors and contemporaries of our Saxon and Norman edifices, were called Gothic; but the style of which the pointed arch is the characteristic feature, was always distinguished as the German manner, *Maniera Tedesca*. The disgrace of applying the opprobrious term Gothic to it attaches itself to an Englishman, Sir Henry Wotton. It was continued by Evelyn, who applied it more directly; and the authority of Sir Christopher Wren finally settled its application. Its injustice is, however, rendered very obvious, by comparing the front of Pisa Cathedral, the best example, perhaps, of Gothic, or merely deteriorated Roman architecture, with that of York Minster, which holds an almost equal rank in the style of which it is an exemplar. The presence of the pointed arch, on the singular oriental-looking cupola of the former, shows it to be one of the latest edifices in its style, overtaken by that before it was completely finished. Within the present century a better taste has been formed, in this country particularly, and has led to the appreciation of that, which is, indeed, our national style; and within that period many attempts have been made to explode the universally-decried, unjust, and totally irrelevant appellation, but without effect. Sir Christopher Wren himself attempted to change it to Saracenic, believing that not merely the arch, but the style generally, was borrowed from the Saracens. It was, however, too late—he had already used the other. Dr Stukely wished to call it Arabian. Some writers called it Italian, others German, others Norman or French, others British, and many have contended for the exclusive term English; and to this last the Society of Antiquaries lent its influence, but with equal inefficiency, for the term Gothic still prevails. Mr Britton, than whom perhaps no man possesses a greater right to affix an appellation to the pointed-arch style, from the splendid services he has done it in the publication of his Cathedral and Architectural Antiquities, wishes to introduce a term which is not at all unlikely to succeed, as it is equally appropriate and independent of national feeling and hypothetic origin. He calls it Christian architecture. This, as a generic term, would admit each nation possessing specimens of it to distinguish its own species or style; and as the varieties of Hellenic architecture are known by the names of the tribes or nations who are presumed to have originated them—Dorian, Ionian, and Corinthian—so might Christian architecture be English or British, German, French, &c for each has its peculiarities. These species would again individually admit of classification, according to the changes each underwent in the course of its career. One strong objection, however, in our view of the case, lies to Mr Britton's distinctive appellation. It is, that "Christian" applies as well, if not better, to the real Gothic style—that which arose on the extinction of Roman architecture, and was subverted by the introduction of the pointed arch, and which, indeed, owed its diffusion and progress, if not its origin, to the Christian religion. We are therefore still left to seek an appellation; and, in the absence of a better, will use the term Pointed, which is not only distinctive, but descriptive; and it has, too, the merit of being general, so that it may mark the genus, while the national species and their varieties may be distinguished by their peculiarities as before.

Plate LXX.

The Pointed Arch was a graft on the Gothic architecture of northern Europe, as the circular arch of the Romans had been on the columnar ordinances of the Greeks; but with a widely different result. The amalgamation in the latter case destroyed the beauty of both the stock and the scion; while in the former the stock lent itself to the modifying influence of its parasitical nursling, gradually gave up its heavy, dull, and cheerless forms, and was eventually lost in its beautiful offspring, as the unlovely caterpillar is in the gay and graceful butterfly.

We have seen that architecture had its origin in religious feelings and observances—that its noblest monuments among the pagan nations of antiquity were temples to the divinity—that the rude nations of the north in the middle ages devoted their energies, after their conversion to Christianity, to the construction of edifices for the worship of the Almighty; and we find, again, that the most extensive and most splendid structures raised by the same people, when the light of learning had begun to shine upon them, and a new and more beautiful style of architecture was introduced, were dedicated to the same purpose. In addition, however, many, hardly less magnificent, and not less beautiful, were raised for the purposes of education, and became the nurseries of science and literature. Kings and nobles also employed architecture in the composition, arrangement, and decoration of their palaces and castles; but still, for domestic purposes, its aid was hardly required beyond the carving grotesque ornaments on the wooden fronts of houses in towns.

When the practice of building houses in stories commenced cannot be correctly ascertained; but it appears to have arisen during the middle ages. We frequently, indeed, find an apparent equivalent for the term *story* used by the ancient writers, both sacred and profane; but it must have reference to something else—some peculiarity of which we are not aware; for none of the ancient re-

mains, whether of public or private structures, give reason to believe that it was a common practice even among the Romans; much less was it likely to be so among the eastern nations, with whom the practice is not very general, nor is it carried to great extent even at the present day. Indeed, without considerable proficiency in the art of construction, it is hardly practicable to build in stories with such slight materials as were used by the Romans in their domestic edifices; and their remains do not evince the requisite degree of proficiency. We find, however, in the oldest existing works of the middle ages, and particularly in some of the secular structures of Venice which are among them, a degree of intelligence evinced in that respect far surpassing any thing in those of the ancients. Possibly the skill was principally acquired in that city from the necessity of making artificial foundations, which consequently required a superstructure not unnecessarily cumbrous; and again, to make slight walls sufficiently strong, they must be skilfully bonded in themselves, and bound together, which could only be done by means of a material possessing considerable length and great fibrous tenacity—whence framed floors of timber. These, by their strength, their obvious utility and convenience, added to the want of space which existed in a thriving and populous community on a very restricted spot of dry land, superinduced, in the second place, the building of additional stories, which would soon be imitated in other places. But in what manner soever the improvement took place, the fact is certain that the acquisition was made; and we find it applied in all the works of the European nations, both ecclesiastical and civil, from the ninth and tenth centuries downwards. The combination of masonry and carpentry in building tended greatly to the advancement of both; for, it being required at times to make them act independently of each other, additional science and art were necessary, as the proportions must be retained that were given to similar works in which they co-operated. Hence the wondrous skill evinced in the vaulted roofs and ceilings, in the towers and lofty spires, of some of our Pointed cathedrals for the one, and the splendid piece of construction in the roof of Westminster Hall for the other. To this point Sir William Chambers, who was no depreciator of the merits of the Romans in architecture, says, "In the constructive part of architecture the ancients do not seem to have been great proficients:"[1] then having referred many of what he calls the "deformities observable in Grecian buildings" to want of skill in construction, he continues, "neither were the Romans much more skilful; the precepts of Vitruvius and Pliny on that subject are imperfect, sometimes erroneous, and the strength or duration of their structures is more owing to the quantity and goodness of their materials than to any great art in putting them together. It is not, therefore, from any of the ancient works that much information can be obtained in that branch of the art. To those usually called Gothic architects we are indebted for the first considerable improvement in construction. There is a lightness in their works, an art and boldness of execution, to which the ancients never arrived, and which the moderns comprehend and imitate with difficulty. England contains many magnificent specimens of this species of architecture, equally admirable for the art with which they are built, the taste and ingenuity with which they are composed." To this Mr Gwilt, in his new edition of Sir William's work, adds in a note, "there is more constructive skill shown in Salisbury, and others of our cathedrals, than in all the works of the ancients put together."

Pointed architecture took root and grew with the greatest vigour in Germany and Great Britain, and in those provinces, principally, of France which were connected with England; but in this country its course is the most marked, and its advances are the most easily traceable. We find in various portions of the same edifice, according to the period of its construction, exemplifications of the style, from the ingrafting of the simple lancet arch on the Norman or Gothic piers in the time of Henry II. to the highly enriched groinings and ramified traceries of the age of Henry VII.; but the changes are so gradual, and are so finely blended, that the one in advance appears naturally to result from that which comes before it. Whether the nations of the Continent, then, borrowed from us, or were themselves originators, it is very clear that we did not borrow; for our structures bear the strongest possible marks of originality, as the advances can be traced from one thing to another on them; and such is not so completely the case with theirs. Moreover, the latest manner, and certainly not the least beautiful, the Corinthian order of Pointed architecture, is almost peculiar to this country. Neither Germany nor France can produce edifices in the style of St George's Chapel at Windsor, King's College Chapel at Cambridge, and Henry VII.'s Chapel at Westminster. The structures of Scotland in the Pointed style so much resemble those of England, that they must be considered of the same school; Roslin Chapel is one of the few specimens which indicate a connection with the Continent. Ireland contains but few examples in any degree of perfection, and they are, of course, of the English school. The German school was next in merit to the English in the practice of Pointed architecture. In the extent and magnificence of its attempts, perhaps, that country excelled; but few of the great structures in Germany were ever completed. In regularity, however, they have generally an advantage over those of England, being mostly in the same manner throughout, as far as they were carried; whereas few of the greater edifices of this country were begun and completed without considerable variations in the style. But the Germans were never so successful in the splendour and beauty of their interiors as the English; indeed in that particular our Pointed structures are strikingly superior to every other: nor is their ornament generally so effective as ours. The Flemish style of Pointed architecture is hardly a variety of the German, but may be classed with it through the whole course of its history. Italy, we have said, possesses but few structures in the Pointed style, and they are for the most part the work of German architects, which their appearance indeed bespeaks. Milan cathedral, or "the Duomo," as it is called, is the most renowned edifice in the style that Italy contains; but it has few beauties in the eyes of those who are accustomed to the models of Great Britain, France, and Germany. The Patriarchal Church of St Mark at Venice is a genus *per se*. It was constructed by a Constantinopolitan architect in the ninth or tenth century, and may be a specimen of the architecture of the Byzantine capital at that time. The few examples in Sicily of the pointed arch may be attributed to the Norman conquerors of that island; and so indeed may most of those which are found in the continental part of the same kingdom. Although France contains many fine specimens of Pointed architecture, it can hardly be considered indigenous to that country. On the German frontier they resemble the German style; and in the provinces which were formerly connected with England they are different, and more like the English styles: cer-

[1] Gwilt's *Chambers's Civ. Arch.* p. 128.

History.

tain it is, that after their connection with this country was broken off, its practice fell into disuse, and nothing of consequence in it was posteriorly produced in any of them. This fact is an argument against the presumption that England was indebted to Normandy and Norman architects for its improvements in Pointed architecture; it tends rather to prove the opposite. It must be confessed, moreover, that there is an air of cumbrous massiveness in the Pointed style of Normandy which renders it peculiar, and perhaps marks its more close relationship with the earlier Norman Gothic. Like the German examples, too, those of France are generally inferior in internal richness and beauty to those of England. Pointed architecture in Spain never acquired that degree of consistency and elegance which might justify us in speaking of the Spanish specimens of it as forming a style. The edifices in Spain of the ages of Pointed architecture are more in accordance with the Moorish than with the European manner, and may perhaps be more correctly considered as an off-shoot of the former than of the latter. Though not in the Pointed style, the Moorish or Saracenic structures in Spain may be referred to here. They are in a very peculiar manner, which, it would appear, their authors brought with them from the East. Probably it grew out of some of the earlier styles of architecture, as the Gothic and Pointed did out of the Roman, and was not the result of design. The really distinctive feature of the Saracenic style is the horse-shoe arch, which is the greater segment of an ellipsis, nearly, on a conjugate chord. The columns from which the arches are sprung are slender, and the superincumbent masses are broad and heavy, giving an air of the intermingling of Chinese and Egyptian, both of which this style may be said to assimilate. The enrichments of Saracenic architecture are very much confined to flat surfaces, the walls being sculptured all over with monotonous ornaments, which produce an effect very similar to that produced by the hieroglyphics on the flat surfaces of the Egyptian temples, and possibly were derived from them. The most distinguished monument of this style in Spain is the Alhamrā at Granada. The most distinguished specimen of Pointed architecture in Portugal is the church of the convent of Batalha, which was constructed by an Irish architect, who appears to have modified the style of his own country (the English), by the manner of the country itself, which is nearly that of Spain.

What the expansive dome is to Roman architecture, the graceful spire is to Pointed. Bell-towers appear to have been added to Christian churches at a very early period; but it is much to be doubted whether the pyramidal pinnacle or spire was ever used before the introduction of the pointed arch, though one or two doubtful examples exist. These, certainly the earliest specimens of it, are simple cones, whose vertical bisection would be nearly an equilateral triangle: the angle at the apex was gradually made less, and as it diminished the altitude was increased, till at length resulted an object even more beautiful than an Egyptian obelisk, which would of itself indeed be a sufficient warranty for the appellation we have given to the style that it crowns. The spire was at first round, solid, and unornamented; it then became polygonal, and finally octagonal, though there are examples of square spires. They are sometimes plainly ribbed, sometimes crocketed, and in some instances pierced; and in the finer examples are almost invariably surmounted by a rich finial in the style of ornament peculiar to the time of its execution. In some cases the whole structure is a pyramis or spire, but most commonly the spire rests on a rectangular and upright tower. The Rev. W. L. Bowles has suggested that the spire was at first built on the bell-tower as a beacon or land-mark for the guidance of the traveller and the distant parishioner; and adduces as evidence, the fact, that in the hilly parts of England spires are hardly to be found except in modern churches. The old village church on a hill has a plain square tower, merely consisting of about two cubes, which can be seen at the greatest distance the nature of the country will allow any object to be distinguished; whereas in the level parts of the country, where a low tower would be lost amidst the foliage of its own churchyard, and be completely indistinguishable at a very short distance, spires are their almost invariable accompaniment. It may be added, that the tapering spire is almost unknown in Italy, and in France it is frequent only in Normandy; but in no part of the Continent is it so common as it is in this country.

We have already given our reasons for thinking that the pointed arch originated in the East; but whether it did or did not, it has been very extensively used in various parts of Asia, and nowhere in more sumptuous edifices, or to such effect, as by the Mohammedan conquerors of India in various parts of that country.

Italian school of architecture.

The opening of the Italian school of architecture on the resuscitated dogmas of Vitruvius was the signal for the extinction of that of the beautiful Pointed style. Fortunately, however, its effects were a full century in reaching this country, and during that period many of our most elegant structures came into being; and many of those of earlier date which had been commenced before, or during the wars of the Roses, and left unfinished, were completed. The first indication we have of the presence of the *Cinquecentist*, the real Goth, is in the tomb of Henry VII., which was executed by Torregiano, an Italian artist, who, it would appear, was obliged to have some respect to the style of the edifice in which his work was to rest; but his preconceived ideas of propriety and beauty were too strong to allow him to omit the characteristics of his school, and the result is a strange mixture of both. From that time the Pointed style was rapidly deteriorated, being overborne by the devices of Italy. On the Continent the latter were already predominant, for during the whole of the fifteenth century the current had been setting from Italy over every part of Europe which received its religion from Rome; and this country was only the last to be overwhelmed by it. Before quitting the part of the subject having reference to our national style of architecture, it may be well to controvert the absurd but too prevalent idea, that we are indebted to foreigners, and particularly Italians, for the excellence of our ancient works. After what has been already said, perhaps it may be unnecessary to do so here, seeing that we have described our specimens of the Pointed style as being not only fully equal in composition, construction, and execution to those of any other country, but as being absolutely in a different manner, having peculiarities which no other nation has ever equalled in beauty and elegance. But, to put the case in a clear point of view: If foreigners were employed to design and execute for us, it is not less strange that they should surpass their own works at home, than that they should make inventions and improvements for us (or let them be called mere variations) which were not in turn executed in their own countries. We know very well that works of architecture and sculpture which have been executed by foreigners in this country, since the explosion of Pointed architecture, are in the style of Italy or France, and not according to the manner prevalent in this country at the time of their execution. Moreover, for one whole century this nation alone adhered to the Pointed style, during which works were produced, that, for originality, exuberance of fancy, and beauty, spirit, and excellence of ex-

History. ecution, have been seldom equalled and never surpassed; while all the architects, artists, and workmen of the Continent were rendered totally unable to assist us by the change which had taken place in their practice. If this required proof, it is proved in the case of Torregiano just referred to, who sculptured Henry VII.'s tomb, and in that of Hans Holbein, who designed architectural works for us in the *classical* manner; and if the Torregianos and Holbeins had been employed during the 15th century, would they not have done the same?

If the architecture of Italy never fell away so much from the more classic style of Imperial Rome as that of the northern nations did, neither did the Italians ever possess that more than equivalent, whose splendid course we have last noticed. Whilst the Pointed style was almost exclusively known and practised in Germany, France, and the British Islands, the Italians were gradually improving on their Gothic style; yet the improvement was more evinced in their secular than in their ecclesiastical structures. Florence, Bologna, Ferrara, Venice, and many other cities of Italy, contain palaces and mansions of the twelfth, thirteenth, and fourteenth centuries, which for simplicity and classical beauty far excel most of those in the same and other places of the three subsecutive centuries. The contemporary churches, however, do not exhibit the same degree of improvement, forming, as it were, an anomaly in the history of architecture; a change in it being first developed in secular structures, and then applied to those devoted to the worship of the divinity; for many of the churches of the fifteenth century are in this, which may be called the early Italian style, or *Trecento*, as that which followed it is known as the *Cinquecento*.[1] Circular arches, and plain continuous horizontal cornices, and pilasters but slightly projected, with simple but generally tasteful and elegant enrichments of foliage and carved mouldings, are the most striking characteristics of the *Trecento;* but columns, and the arrangements depending on them, except as collocated with pilasters, are very infrequent in it. In various parts of Italy, and particularly in Venice and some of the Venetian cities, this style produced many of its best works, both secular and ecclesiastical, even during the fifteenth century; but it gradually gave way to, though in some instances its influence may be traced even when it had been overborne by, the new style.

The first step taken towards the reformation of architecture was by Filippo Brunelleschi, a Florentine architect, who was employed to finish the cathedral or duomo of his native city early in the 15th century; a work which had been commenced more than a century before on the design of Arnolpho, a Florentine also, but which still required the cupola when its completion was intrusted to Brunelleschi. The edifice is in the Italian Gothic style, slightly modified by what we have termed the *Trecento*, which his superior taste and talent induced him to attempt to supersede, and bring the world back to the classic style of ancient Rome. The construction of the cupola gained him great reputation and the confidence of the public, which he employed to advance his favourite scheme. To use the words of an Italian writer on the subject, "On the example of so wise and skilled a man, other architects afterwards devoted themselves to free architecture of the monstrosities introduced by barbarism and excessive license, and to restore it to its primitive simplicity and dignity."[2] But to what did they have recourse to effect this? Did they examine and study the remains of antiquity in Greece and Rome, in Italy and elsewhere? No! they referred to the writings of an obscure Latin author, who professed to give the principles and practice of architecture among the Greeks and Romans, but paid no more attention to the existing architectural works of those nations than if they had never been, although one could hardly walk the streets of any of the old cities in the south of Italy without seeing Roman edifices, whilst Rome and its vicinity was, as it still is, full of them. All the use, however, that these self-called "restorers" of architecture made of the works of the ancients, was to use them as lay-figures, or frame-work, to model on, according to the proportions and directions given by Vitruvius; and the effect was formality and mannerism in those who adhered to the dogmas of the school, and wild grotesqueness in those who allowed themselves to wander from them, whilst simplicity, and its consequence good taste, were effectually banished from the works of them all. History.

It will be necessary here, perhaps, before we advance further in our remarks on the Italian school, to disabuse the public mind as to the merit of the works of Vitruvius, whose anilities have so long passed for authorities, that a writer would be suspected of prejudice who spoke of them slightingly without adducing reason and evidence to prove them valueless; except, indeed, as records of the architectural practice, and the opinions and acquirements of an architect of a distant age. It is of very little consequence that Vitruvius is only known by his own writings, but that mention of him by a contemporary or other ancient author would probably determine the age in which he lived. From several things he mentions, and his inscription or dedication to the "Imperator Cæsar," it has been concluded that he lived in the time of Augustus; but certainly without sufficient reason; for if the man he speaks of as the son of Masinissa had been the son of the celebrated Numidian of that name, in the course of nature neither he nor Vitruvius could have lived to the time of Augustus. But he addresses an emperor who succeeded his father an emperor, and speaks of a temple of Augustus; so that he must have been a contemporary of some period of the empire. If that period had been the Augustan, he would doubtless, have made some reference to some of the many distinguished men of that age, or have been referred to by some of them if he had himself been at all known or distinguished as his admirers insist he was; neither of which is the case; and, moreover, his language is not that of an educated man of the Augustan age. This, however, does not affect the merit of his work as a treatise on architecture; but his fables about the origin of building, the invention of the orders, and the arrangements which grew out of certain modes of construction, do so; by proving his total ignorance not only of the architectural works of the more ancient eastern nations, but of those of Greece itself, which he professes to describe. Now his classical taste, in consequence of his knowledge of antiquity, is vaunted by Perrault, one of his commentators, and given by him as a reason why Vitruvius was not much employed by the whimsical Romans in their love of variety, to which he would not administer. How far his knowledge of antiquity, that is, according to himself, of the works of the Greeks, extended, may be readily determined by comparing the designs of Greek structures, made by Perrault and others, according to the directions of Vitruvius, with the Greek structures

[1] *Cinquecento* means literally *five hundred*, but it is used as a contraction for *fifteen* hundred, or rather for *one thousand five hundred*, by the omission of *mille*, the century in which the revival of architecture, of which we are about to speak, took place; and the manner consequent is so designated. *Trecento* would be *three* hundred, or the *third*, for the thirteenth century.

[2] *Le Fab. e i Disegni di A. Palladio* da O. B. Scamozzi, tomo i. p. 4.

themselves as they exist at the present time, and are faithfully delineated in various modern works, but especially in Stuart and Revett's *Antiquities of Athens.* It is indeed not less strange than true, that not a single example of Greek architecture will bear out a single rule which Vitruvius prescribes, professedly on its authority; and not an existing edifice, or fragment of an edifice, in form or proportion, is in perfect accordance with any law of that author, nor indeed are they generally referable to the principles he lays down. Examples might be cited almost to infinity in support of this statement, and to prove the inutility of a work consisting of mere descriptions without delineations, even if it were otherwise correct. The latter may certainly be supplied from the ancient remains when they exist; but to a man in possession of the specimens, descriptions and directions for their composition are quite unnecessary. Even Sir William Chambers, a distinguished disciple of the Italian or Vitruvian school, speaks very lightly of the advantage to be gained from the study of the Vitruvian principles of construction; and Mr Gwilt, in the introductory treatises to and notes on Sir William Chambers's work, has done much to undermine the authority, by exposing the absurdities and fallacies of the Magnus Apollo of pseudo-classical architecture. A student would acquire as correct a knowledge of history and geography from the Seven Champions of Christendom and Gulliver's Travels, as of architecture from the text of Vitruvius!

The adoption of the Vitruvian laws by the Italian architects of the 15th century led to the formation of the "Five Orders." It will have been observed that, in speaking of the course of Greek and Roman architecture, the Doric, Ionic, and Corinthian styles were mentioned. Vitruvius describes, in addition to these, another, which he calls Tuscan—possibly a style of columnar arrangement peculiar to Italy, and most likely of Etrurian origin; but, in the absence of delineations, the *Cinquecentists* could only apply the proportions he laid down for it, to what appeared to approximate them in the ancient remains; and hence arose a fourth, or "the Tuscan Order." It is, however, a mere modification of the Roman debasement of the Doric, and may be considered, in its present form, as of purely modern Italian origin. The same "Revivers," on looking among the ruins of ancient Rome for the forms of their Vitruvian orders, found specimens of a foliated ordinance, which the bad taste of the Romans had compounded of the foliated and voluted styles of the Greeks. This was seized upon as a fifth style, subjected to certain rules and proportions, and called "the Composite Order." The very poor Roman specimens of Doric and Ionic fitted themselves without much difficulty to the Vitruvian laws; but the examples Rome afforded of the Corinthian were less tractable, and being as various as they are generally beautiful, they were all passed over, and their places supplied by a mere changeling—an epitome of the Vitruvian theory. Thus we have the "Five Orders" of the Italo-Vitruvian school, and in this manner they are arranged: *First,* the Tuscan, of which there is no recognised example of antiquity, but which owes its form to the descriptions of Vitruvius and the fancies of the revivers; *second,* the Doric, a poor and tasteless arrangement of the general features of the style on a Roman model; *third,* the Ionic, which is almost as great a debasement of the Grecian originals, and was produced in the same manner as the last-mentioned; *fourth,* the Corinthian, a something totally unlike the ancient examples of both Greece and Rome in beauty and spirit; and, *fifth,* the Composite, an inelegant variety of the Corinthian, or a hybrid mixture of the horned or angular-Ionic volutes, with a deep necking of the foliage of the preceding order.

The first to publish this system was Leon Battista Alberti, a pupil of Brunelleschi. He has been followed by many others, the most distinguished of whom are, Palladio, Vignola, Scamozzi, Serlio, and De Lorme, architects; and Barbaro, a Venetian prelate, and an esteemed translator of, and commentator on, Vitruvius. None of these, it must be understood, agreed with any other of them, but each took his own view of the meaning of their common preceptor; and yet none of their productions evince the slightest approach to the elegance of form and beauty of proportion which distinguish the classic models of the columnar architecture of antiquity. Palladio and Serlio were the first to publish delineations and admeasurements of the Roman architectural remains in Italy; but the total absence of verisimilitude to the originals, and, in many cases, the absolute misrepresentations, in both works, prove how incompetent the authors were to appreciate their merits; and the exaggeration of their defects proves with equal clearness the general bad taste of the school in which they are masters. The worst qualities of the Roman school of architecture were embraced and perpetuated by the *Cinquecento.* The inharmonious and unpleasing combinations which arose out of the collocation of arches with columnar ordinances became the characteristics of the Italian: unequal intercolumniations, broken entablatures, and stylobates, enter alike into the productions of the best and of the worst of the *Cinquecento* architects. The style of this school is marked, too, by the constant attachment of columns and their accessories to the fronts or elevations of buildings; by the infrequency of their use in insulated (their natural) positions to form porticoes and colonnades; by the thinness or want of breadth in the smaller members of their entablatures, and the bad proportion of the larger parts, into which they are divided, to one another; by the general want of that degree of enrichment which fluting imparts to columns; by the too great projection of pilasters, and the inconsistent practice of diminishing, and sometimes fluting them; by the use of circular and twisted pediments, and the habit of making breaks in them to suit the broken ordinance they may crown; and by various other inconsistencies and deformities, which will be rendered more evident when we come to treat of the style in detail. The merit of the Italian school consists in the adaptation and collocation of the prolate hemispheroidal cupola, which appears to have grown out of its opposite in the Roman works during the Gothic ages, as we find it in the early cathedrals; though it is highly probable that the idea was brought from the East, in the forms exhibited by the cupolas of St Marks at Venice, and of Pisa Cathedral. A very noble style of Palatial architecture also was practised by many of the Italian architects. It consists of the use of a grand crowning cornice, running in one unbroken line, unsurmounted by an attic, or any thing of the kind, superimposing a broad, lofty, and generally well-proportioned front, made into graceful compartments, but not storied, by massive blocking courses and other things, which are at the disposal of the judicious architect. Not unfrequently, however, the faults of the school interfere to injure a composition of this kind; for, to produce variety in the decorations of the windows, some of them have been made like doors, with distyle arrangements of columns, surmounted by alternations of circular and angular pediments, and sometimes with all the vagaries which deform the front of an Italian church. It is indeed the ecclesiastical architecture of the school in which its faults are most rife and its merits most rare. An Italian church possesses nothing of the stern simplicity and imposing grandeur of an Egyptian sacred structure—nothing of the harmonious

History.

beauty and classic dignity of a Grecian fane—nothing of the ornate and attractive elegance of a Roman temple—and nothing truly of the glittering grace and captivating harmony of a Pointed cathedral. No other style of architecture presents so great a contrast, in any two species of its productions, as the Italian does, in one of its ordinary church fronts, with the front of a nobleman's mansion or palazzo, in the manner already referred to; and in no city of Italy is the contrast so strong, by the egregiousness of the examples it contains of both, as Rome. The stately portico is hardly known in Italian architecture; and in the rare cases in which insulated columns are found, they are for the most part so meagre in themselves, and so thinly set, according to the Vitruvian laws, that the effect produced by them is poor and wretched in the extreme. This applies most particularly to Italy itself: in some other countries, and especially in this, those architects who have been of the Italian school have generally preferred the proportions and arrangements which they found in the Roman examples of antiquity, to those laid down by their Italian masters. Still, Italian church architecture boasts the cupola,—certainly its redeeming feature; and the architects of Italy must have full credit for the use they have made of it, both internally and externally. Perhaps no two edifices display more, and in a greater degree, both the merits and defects of the school which produced them, than the Farnese palace and the basilica of St Peter in Rome. The principal front of the former edifice is exquisite in its proportions, but frittered in its details. It has an immense crowning cornice, whose general effect is surpassingly grand; but the mouldings are too much projected, and its vertical parts want the breadth which the blocking courses possess. The lowest of its three tiers of windows is characterized by the most charming simplicity and good taste in almost every particular; but the other two are crowded with sins against both those qualities, in the dressings of the windows. The cortile and back front, though both very differently arranged from the front, and from each other, are not less filled with contrarieties; and so of the structure throughout. The front of St Peter's is not more distinguished by its magnitude than by its littleness and deformity. It contains the materials of a noble octaprostyle, and consists of an attached tetrastyle. It is divided into three unequal stories, within the height of the columns, whose entablature is surmounted by a windowed attic. In length it is frittered into a multitude of compartments, between which not the slightest harmony is maintained; while tawdriness and poverty are the distinguishing characteristics of its detail. A total absence of every thing which produces grandeur and beauty in architecture, marks, indeed, the whole of the exterior of the edifice, except the glorious cupola, than which architecture never produced a more noble and magnificent object. Internally, the structure is open to similar praise and similar dispraise. Gorgeousness in matter and meanness in manner characterize the interior of St Peter's, except the sublime concave which is formed by its redeeming feature without.

Plates LXIV. LXV. and LXVI.

The *Cinquecento* architects of Italy were exceeding mannerists: but besides the manner of the school, each had his own peculiarities; so that there exists in their works what may almost be called monotonous variety. Brunelleschi's designs are distinguished by a degree of simplicity and comparative good taste, which causes regret that he had not referred more to the remains of antiquity in Italy, and sought out those of Greece, and less to the dogmas of Vitruvius; for then his works would have been more elegant than they are, and the school he founded would have done him much more honour than it does. The works of Bramante possess a more classical character than those of any other architect of the school. Bramante's design for St Peter's was preferred by Pope Julius II. to a great many others by the most esteemed men of the time. He it was who suggested the cupola; but, unfortunately, after his death men of less taste and talent were allowed to alter the design, and the edifice has resulted very differently from what it would have done had Bramante been adhered to. This we judge from his works generally, and not from any positive knowledge of the design, which indeed does not exist. The elder Sangallo was far inferior to his contemporary and rival Bramante, and his works are full of the faults of the school. Michel Angelo Buonaroti was a man of great genius, but of coarse taste in architecture; and to him may be attributed many of the coarser qualities of the Italian style. His principal works are the buildings of the Capitol, and the College della Sapienza in Rome, and the Laurentian Library at Florence; and these are all distinguished for their singular want of architectural beauty and propriety in every particular. Michel Angelo was the Dante of Italian painting, but the Berni of its architecture. Raffaelle, too, had a very bad style in architecture, and so indeed had almost all the painters who professed to be architects also. They generally carried to extremes all the faults of the school. Sansovino and Sanmichele were men of considerable talent: their works display more originality and less servility than those of most of their contemporaries. Peruzzi was less employed than many who had not half his merit: his productions are with reason considered among the most classical of the Italian school. Vignola had a more correct taste than perhaps any other Italian architect of the 16th century: his works are indeed distinguishable by their superiority in harmony of composition and in general beauty of detail. Palladio very much affected the study of the antique, but his works do not indicate any appreciation of its beauties. He appears to have been very well qualified by nature for an architect, but spoiled by education. He did not look at the remains of antiquity with his own eyes, but with those of Vitruvius and Alberti, and he seems to have been too much influenced by the admired works of some of his predecessors. Palladio made greater use of insulated columns than the Italian architects generally, but his ordinances are deficient in every quality that produces beauty; his porticoes may be Vitruvian, but they certainly are not classic; and all his works evince that he studied the Colosseum, the Theatre of Marcellus, and the Triumphal Arches, more than the columns of Jupiter Stator and Mars Ultor, the Temple of Antoninus and Faustina, the Pantheon, the Portico at Assisi, and the other classic models, which he drew, but clearly did not appreciate. His columns upon columns, his attached and clustered columns, his stilted post-like columns, his broken entablatures, his numberless pilasters, straggling and unequal intercolumniations, inappropriate and inelegant ornaments, circular pediments and the like, are blemishes too numerous and too great to be passed over because of occasional elegance of proportion and beauty of detail. Scamozzi did not improve on the style of his master, which, however, he very much affected. Indeed the term *Palladian* has long been in general use throughout the civilized world for beautiful and excellent in architecture, so that it cannot be wondered at that Palladio's pupils and successors should imitate him; nor is it surprising that they did not surpass, or even equal him, for they were taught to look to his works as the *ne plus ultra* of excellence. Giacomo della Porta, a contemporary of Palladio, followed Michel Angelo in several of his works, and imbibed much of his manner, on which

History.

he certainly improved; but still his own is far from being good; Della Porta was much employed in Rome; and it fell to him, in conjunction with Domenico Fontana, to put the cupola on St Peter's. Fontana's style of architecture is not particularly distinguished for its good or bad qualities; he obtained more reputation as an engineer than as an architect, having been engaged in removing and setting up most of the obelisks which give so much interest to the architectural scenery of Rome. The Lunghi, father, son, and grandson, the Rainaldi, Maderno, Borromini, Bernini, Carlo Fontana, Fuga, Vanvitelli, and many others in the course of the seventeenth and eighteenth centuries, carried the peculiarities of the Italian school to the greatest extremes. Of those enumerated, Bernini was perhaps the least offensive, and Borromini the most extravagant; but throughout that period, except in extreme cases, individual manner is less distinguishable, and that of the school more strongly marked.

It may be gathered from the preceding remarks, that the secular architecture of the Italian school is generally preferable to the ecclesiastical, and that the architects of the fifteenth and sixteenth centuries were generally superior to those who followed them. In Italy the school has not yet ceased to exist, nor indeed has its style ceased to be studied. Designs are still made by the students of the various academies in the manner of the *Cinquecento*, and on the models with which the country abounds. The precepts of Vitruvius are yet inculcated, and the works of the men whose names we have mentioned are looked up to as master works of architecture in the country which contains the Roman Pantheon and the Greek Neptunium, besides the power of referring to the more exquisite works of Greece herself.

Influence of the Italian school.

In the fifteenth century such was the reverence of men for the revived works of ancient literature and science, that the profession of the Italians, that they had restored ancient classical architecture on the precepts of an architect of the Augustan age, was sufficient to open the way for them all over civilized Europe. In the course of that and the following century Italian architecture was adopted and Italian architects employed in France, Spain, Germany, Great Britain, and their respective dependencies; and now, in the nineteenth century, Vitruvius and Palladio are as predominant on the shores of the Baltic as on those of the Mediterranean Sea; though in this country and in some parts of the Continent their influence is considerably diminished since the time of Inigo Jones and Claude Perrault. It has been already remarked, too, that the *Cinquecento* was later in gaining a footing here than on the Continent, in consequence of the existence of a beautiful national style of architecture, which our ancestors do not appear to have been induced to resign to the barbarian innovators of the South, as readily as the interjacent nations were to give up theirs; for which indeed the reason exists in the greater attractions of ours, and the consequent greater difficulty of inducing the nation to part with it. The French, though they received the Vitruvian architecture from the Italians, were patriotic enough, as soon as they had acquired its principles, to confine the practice of it almost entirely to native architects, in whose hands it assumed a different character from that which it possessed in Italy, and became what may be called the French style of *Cinquecento*. Its ecclesiastical structures are less faulty than are those of the corresponding period in Italy, but its secular edifices are as far inferior to those of that country. The grand palatial style, which is exemplified in the Farnese palace in Rome, never found its way into France; but instead, there arose that monstrous and peculiarly French manner, of which the well-known palaces of the Tuileries and Luxembourg are egregious examples. In the age of Louis XIV. the French appear to have reverted to the Italian manner in a certain degree; for the palace of Versailles includes almost all the extravagancies of that school in its worst period, and contains moreover architectural deformities which Italy never equalled till it imitated them. They consist in the style of enrichment which is distinguished by the name of that monarch in whose reign it had its origin, and of whose gross taste and vulgar mind it is an apt emblem. The same period produced one of the most classical architects of the French school—its Palladio or Inigo Jones, Perrault, whose design for the buildings of the Louvre was preferred to that of Bernini, though indeed the preference was no compliment to the one nor discredit to the other, considering to whom the decision was of necessity referred. The Hôtel des Invalides is of the same age: it exhibits the graces of the Italian cupola, surmounting a composition which includes more than all the faults of St Peter's in Rome. The church of Sainte Genevieve, or the Pantheon, a work of the following reign, was intended to be in the ancient Roman style, and of Roman magnificence; but it is rather papally than imperially so. Ancient Rome was regarded in the columnar ordinance, but modern Rome in the architectural composition. In it the ecclesiastical style of the *Cinquecento* is commingled with the simple beauties of Roman architecture, almost indeed to the destruction of the latter: to this structure also there is a handsome cupola. Of late years the works of the ancients have been studied by the architects of France, greatly to the amelioration of their style; as yet, however, they are but imperfectly acquainted with the peculiarities of the Greek, and many of them still appear to retain their devotion to Vitruvius and the fifteenth century. Spain servilely received the Italo-Vitruvian architecture, and to the present day knows no other. Less patriotic than the French, the Spaniards have for their greatest works employed the architects of France and Italy. The Escurial, though the work of a native architect,[1] does little credit to Spanish art. The Italian Revival was the means of extinguishing the Pointed style of architecture in Germany, and certainly without affording it an equivalent. Italian architects were employed in Germany, and Germans acquired their manner; but they did not improve it, nor did they make it productive of so many good effects as the Italians themselves did. The change in religion which supervened the change in architecture in so large a part of Germany, may have tended to prevent the latter from acquiring that degree of exuberance there which it did in Italy; but even in Catholic Germany the splendid Pointed cathedrals have never given way to modifications of the pseudo-classic St Peter's. In the use of *Cinquecento* architecture for secular structures, it may be truly said that the Germans have not excelled the Italians; nor, on the other hand, have they equalled them in the absurdities and extravagancies which are so frequently observable in the works of some of the latter. The Germans also have lately turned their attention to the works of the ancients, and the fruit of it is already evident in many parts of the country, and most particularly in Prussia: still, however, they appear to have yet to learn the right use of the Greek models, and a proper sense of the exquisite perfection of their detail; as well as to emancipate themselves from many of the trammels of the Vitruvian school. The northern continental nations have been dependent on Germany, France, or Italy for their architecture, and can produce nothing that gives them a claim to our consideration in such a review as the

[1] It has been sometimes erroneously attributed to a Frenchman. The work was begun by Juan Bautista de Toledo in 1563, and completed by his pupil Juan de Herrera in 1584.—*Descripcion del Escorial* por Francisco de los Santos; *Viage de España* por Antonio Ponz; *Varia Commensuracion* de Juan de Arfe; Laborde, *Itin. Descrip. de L'Espagne*, t. iii.; Townsend's *Spain*.—Ed.

History.

present. St Petersburg is exclusively the work of architects of the nations just enumerated, and presents a mass of the merest common-places of Italian architecture, in structures calculated by their extent, like Versailles, the Escurial and St Peter's, to impose on the vulgar eye.

We have already more than once had occasion to refer incidentally to the introduction of *Cinquecento* architecture into Britain; and in noticing it more particularly, and tracing its course, we are saved the trouble of keeping up a distinction between the different parts of our triple nation, because, at the time it actually crossed the channel, the amalgamation of the kingdoms had taken place by the union of their crowns on the head of the Scotish sovereign.

English architecture.

When the Pointed style received its deathblow in England, in the reign of Henry VIII., it did not immediately cease to exist; nor was it immediately succeeded by the Italian when it became extinct. It was gradually declining through all the 16th century, during the latter part of which period, what has been called the Elizabethan style became somewhat permanent. It consists of a singular admixture of the Italian orders, with many peculiarities of the Pointed style, and in many examples the latter appears predominant. With such difficulty, indeed, did that fascinating manner give up its hold on the minds of men in this country, that the *cinquecentists* appear to have relinquished the hope of effecting its destruction,—unfortunately, however, not until the injury was done; and for some time we were left without a style of any kind, unless that may be called by the name which marks the edifices of the reign of James I., and of which the oldest parts of St James's palace are a specimen.

The destruction of the Pointed style has been referred by some to the change in religion which took place under the Tudor line of English monarchs; but such was certainly not the case. It was the "Reformation" of architecture in Italy, and not that of religion in Great Britain, that effected it; and it may be doubted whether the change would not have taken place sooner in this country, if its connection with Italy had not been so materially affected by the moral change here, and so delayed that of architecture; for it was Germany and France that supplied us with architectural reformers during the reigns of Henry VIII. and his children, and not Italy, whose professors might possibly have obtained more credit than their disciples did.

So dilatory were we, indeed, in the cultivation of the Italian style, that the first professor of it who was actually employed on edifices in this country came hither from Denmark! It is true, he was an Englishman; but so little hope did he appear to have of success at home, that he accepted an invitation from the king of that country, when he was at Venice, whither he had gone to study painting; but becoming enamoured of architecture, as he saw it in the works of Palladio, he had made that his study instead, and had already acquired considerable reputation in that city, when Christian IV. of Denmark invited him to his court to occupy the post of his first architect. A train of circumstances, to which we need not here advert, brought him to England a few years after James I. came to the English crown, and he was appointed architect at first to the queen, and subsequently to Henry prince of Wales. But he does not appear in consequence to have then obtained employment; for after the death of the prince, he went again to Italy, where he remained till the office of surveyor general, which had been promised him in reversion, fell vacant. This was the celebrated Inigo Jones, who has been called the English Palladio; and indeed he succeeded so well in acquiring the peculiar manner of that architect, that he richly deserves whatever credit the appellation conveys. It is unfortunate, however, for his own reputation, that he had not looked beyond Palladio and their common preceptor Vitruvius, to the models the latter pretends to describe; in which case he might have been the means of restoring, or at least of introducing, to his own country, the truly classical architecture of the ancients. But instead of that he brought nothing home but Italian rules and Italian prejudices. Jones commenced the truly Gothic custom of thrusting *Cinquecento* fittings into our Pointed cathedrals, by putting up an Italian screen in that of Winchester; and he barbarized the ancient cathedral of St Paul in London, by repairing it according to his notions of Pointed architecture, for it was in that style, and affixed to it an Italian front. Fortunately the great fire supervened, and made room for the present magnificent structure, by clearing away that early specimen of pseudo-classic taste. Of the Palladian style, however, it must be confessed Jones was a complete master. He designed a royal palace which was to have been built at Whitehall, in a manner as far superior to those of Versailles and the Escurial, as the works of Palladio are to those of Borromini. The only part of Jones's design ever executed is the structure called the Banqueting-House, whose exterior is an epitome of many of the faults, and most of the beauties, of the Palladian school. It rises boldly from the ground with a broad, simple, and nearly continuous basement or stereobate, and the various compartments of its principal front are beautifully proportioned; but the circular pediments to the windows, the attached unfluted columns, with broken entablatures and stylobates, the attic and balustrade, though they be the materials of Palladian, it may be confidently denied that they are consistent with classical architecture. Another well-known work of this architect is the Italo-Vitruvian Tuscan church of St Paul, Covent-Garden, whose eastern portico is well-proportioned in general, but grossly deformed in detail.

Architecture was in abeyance in this country, again, from the troublous times of Charles I. till the restoration of the monarchy in the person of his son, whose French taste would have completely Gallicized the architecture, as well as the manners and morals, of the nation, if the resplendent genius of Sir Christopher Wren had not been present to avert the infliction, or rather to modify it; for it cannot be denied that the influence of the French manner had an effect on the architecture of this country from that period down to the middle of the last century. Indeed Wren himself only knew the style he practised from books and the structures of France, except the few that existed of Inigo Jones in this country; and, in consequence of his visit to France, the peculiarities of the French style are obvious in many of his less esteemed works. Fortunately, however, he was proof against the grosser peculiarities of the *Cinquecento*, whether in the books of the Italians or in the edifices of the French; and his own productions evince that he had imbibed much of the spirit of the antique monuments of Italy, which he could have known only from engravings, and those very imperfect ones. The field that was opened to his genius by the great fire of London in 1666, and its result, are equally well known. It is true that the general offuscation of taste and feeling with regard to the Pointed style extended even to him. Wren was guilty of many offences in that respect, besides giving authority to the opprobrious term Gothic; and in no case more so than in the construction of the towers to Westminster Abbey, which are a lasting proof of his ignorance of its most obvious principles. Nevertheless, to the influence of our beautiful native style on his mind, architecture is indebted for some of its most charming works. If Wren had not been accustomed to contemplate the graceful and elegant pyramids or spires of his native country, he would never

History. have originated the tapering steeple, in the composition of which with the materials of Italian architecture he still stands as unrivalled as he was original. Witness the steeples of Bow Church and St Bride's in London, the former of which is hardly surpassed in grace and elegance by the Pointed spires themselves. It must remain a constant subject of regret that this great head of the English school of *Cinquecento* architecture did not know the remains of ancient Greece and Rome from personal observation. With his splendid genius and fine taste, if he had not been imposed on by the specious pretence of the Italo-Vitruvian school, his works would have been models for imitation and study, as they are objects of admiration: as it was, he avoided many of the faults of that school, and improved on many of its beauties. Without knowing the Greek style at all, and knowing the Roman only through imperfect mediums; without, indeed, ever having seen an example of either; whenever he has varied from the Italian practice, it has been towards the proportions and peculiarities of the Greek! The great west front of St Paul's, though it is said to be imitated from that of St Peter's in Rome, or rather from what it was proposed to be, with the two towers to form its wings, is a much finer, a more imposing, and more classical specimen of architecture than its prototype; for the advantage the latter should have in being of columns in one height is lost entirely in their poverty and in the miserable arrangement of the whole front; whereas that of St Paul's is in two noble pseudo-prostyle and recessed porticoes, with the columns fluted, and generally conceived and executed in much better taste than those of St Peter's. The entablatures, though massive, are finely proportioned, and sufficiently ornate to be elegant; they are, too, quite continuous, and the upper one is surmounted by a noble pediment, whose pyramidal form gives at the same time dignity and a finished appearance to the whole front. The coupling of the columns, however, and the putting of one columnar ordinance over another, can only be defended by the practice of the Italian school; though, in the present case, both are rendered less offensive by the judicious management of the architect. Nothing shows more strikingly the superiority of St Paul's to St Peter's, as an architectural composition, than a parallel of their flanks. The great magnitude of the latter may strike the vulgar eye with admiration in the contrast; but the rudest taste must appreciate the surpassing merit of the former in the form and arrangement of the cupola, and the noble peristyle with its unbroken entablature and stylobate, out of which it rises, when compared with the sharper form and depressed substructure of that of St Peter's. The superiority of St Paul's in the composition of the main body of the edifice is not less in degree, though perhaps less obvious, than in the superstructure. In the one it is broken and frittered, and in the other almost perfectly continuous, in broad, bold, and effective masses.

Plate LXIV.

The history of the works of Sir Christopher Wren is the history of the architecture of the period in this country; and as it must be admitted that he was not so successful in the composition of the architecture of secular structures as of ecclesiastical, it will follow that our secular edifices of that time are of inferior merit. If it were not indeed an historical fact, it would hardly be credited, that Chelsea College, the old College of Physicians in London, and the halls of some of the city companies, are by the architect of Bow Church and St Paul's.

The style introduced by Sir John Vanbrugh, who may be said to have succeeded Sir Christopher Wren in the direction of architecture in England, was distinguished by massiveness unsuited to the style in which he built, which was of course Italian. It was, however, free from the vagaries and extravagancies which characterize that style generally in other countries at the same period, but was certainly more suited to the soberer character of ecclesiastical than of secular structures, whereas his principal works were noblemen's mansions. Vanbrugh's faults were generally those of Michel Angelo: he was a painter's architect, and did not understand beauty of proportion and detail so well as the pictorial arrangement of lights and shadows; to produce which in the *Cinquecento* it is almost necessary to part with all the higher beauties of architecture. Hawksmoor added to the style of his master that noble ornament in which Italian works are so very deficient —a prostyle portico. His compositions are marked by severe simplicity, and only want to be absolved from a few faults and enriched with a few elegancies to be among the best of modern times. Not the least distinguished architect of the same age (the first half of the 18th century) was the Earl of Burlington, who was a passionate admirer of the style of Palladio and Inigo Jones. Many of the edifices erected by Kent are believed to be from the designs of that amiable nobleman, who, with considerable talent, was, however, a somewhat bigoted devotee to Vitruvius and the *Cinquecento* generally, as well as to Palladio in particular; for he has frequently used columns representing half-barked trees, in conformity with the silly tales of Vitruvius, and the sillier whims of his disciples The portal of his own house in Piccadilly, and that of the King's Mews, are special examples of this bad taste, and of other faults of the school besides. Lord Burlington built for himself at Chiswick a villa on the model of the Villa Capra, or Rotonda, near Vicenza—a structure which has been called the masterpiece of Palladio. In form and proportion it is certainly elegant, but its details strongly exhibit the poverty of Italian columnar architecture, when unaided by the frittering which is its bane, and almost its sole dependence for effect. Gibbs was a contemporary of the same period. He too, like Hawksmoor, had imbibed a taste for the classic prostyle portico, which he evinced in St Martin's church in London; but that he also was in the trammels of the Italian school is no less evident, in the same structure, to a considerable extent, and still more so in the church of St Mary in the Strand, which is a bad specimen of architecture, and a favourable one of its style. During the following half-century (the latter half of the 18th) Sir William Chambers and Sir Robert Taylor were the most distinguished architects of this country. They were both men of talent and genius, who had availed themselves of the remains of Roman antiquity to good purpose; for as yet those of Greece were either unknown or unappreciated; and the former of them has left us, in the Strand front of Somerset House in London, perhaps the best specimen of its style in existence. Other parts of the same edifice, however, are far from deserving the same degree of praise: indeed, as an architectural composition, the river front is altogether inferior in merit to the other, though of much greater pretence. The inner fronts to the great quadrangle, though exhibiting good parts, are, as a whole, not above mediocrity. An air of littleness pervades them; and the general effect of the fronts themselves is made still worse by the little clock towers and cupolas by which they are surmounted; and to this may be added the infinity of ill-arranged chimneys, which impart an air of meanness and confusion that nothing can excuse. While Sir William Chambers and a few others were applying the best qualities of Italian architecture, indeed improving its general character, and, it may be said, making an English style of it, there were many structures raised in various parts of the country in a manner hardly superior to that of the time of James I; structures in which all the meanness and poverty of the

History.

Cinquecento are put forth, without any of its elegance of proportion, or that degree of effectiveness which men of talent contrived to give it. During the same period, too, the seeds of a revolution were sown, which has almost succeeded in ejecting the Italian style and its derivative from this country, without perhaps having as yet furnished a complete equivalent.

In the year 1748 James Stuart and Nicholas Revett, two painters pursuing their studies in Rome, having moreover paid some attention to architecture, issued " Proposals for publishing an accurate description of the Antiquities of Athens, &c." These proposals met with general approbation, and in consequence they determined on prosecuting their plan; but various hinderances prevented their arrival in Athens till March 1751, when they commenced measuring and delineating the architectural monuments of that city and its environs. In this work Messrs Stuart and Revett were unremittingly employed (as far as their own exertions went, for they were frequently interrupted by the Turks) for several years, so that they did not reach England with the result of their labours until 1755; and, by a series of almost unaccountable delays, the first volume of their work did not appear until the year 1762. Sixteen years more expired before the second issued from the press; and the third was not published until 1794, being nearly fifty years from the time the work was first announced! Avarice and envy had induced a Frenchman of the name of Le Roy, who was at Rome when our countrymen issued their proposals, to forestall them with the public, and rob them of the profit and reputation they were so hardly labouring to earn. This man went to Athens, and in a very short time collected some loose materials, with which he published at Paris, in 1758, a work which he called *Les Ruines des plus beaux Monumens de la Grèce, &c.*, in which he makes not the slightest mention of Stuart and Revett, nor of their labours or intentions, with all of which he was well acquainted. This work is moreover notoriously and grossly incorrect; so incorrect indeed, as to make it difficult of belief that its author ever saw the objects of which he professes to give the representations. Such as it is, however, it was from M. le Roy's work that the public had to judge of the merits and beauties of Greek architecture; for we have said that the first volume of Stuart and Revett's did not appear for several years after it, and that does not contain any pure specimen of the national or Doric style: the second, which does, was not published for twenty years after Le Roy's. Considering, therefore, the source from which the public had to derive information on the subject, it can hardly be wondered at that Greek architecture was vituperated on all sides; and by none with greater acrimony than by Sir William Chambers, whose apology must be, ignorance and the prejudices of education. He really did not know the style he carped at; and his education in the Italo-Vitruvian school had unfitted him for appreciating its grand, chaste, and simple beauties, even if he had known it. Notwithstanding the misrepresentations of Le Roy, the vituperations of Chambers, the established reputation of Italian architecture, and the trammels which Vitruvius and his disciples had fixed on the public mind, when Stuart and Revett's work actually appeared, the Greek style gradually advanced in esteem, by dint of superior merit alone—for it has had no factitious aids; and since that period Greece and all her colonies which possess remains of her unrivalled architecture have been explored, and we now possess correct delineations of almost every Greek structure which has survived, though in ruins, the wreck of time and the desolation of barbarism. To our country and nation, then, is due the honour of opening the temple of Greek architectural art,—of drawing away the veil of ignorance which obscured the beauties it contains,—and of snatching from perdition, and consequent oblivion, the noble relics of ancient architecture which bear the impress of the Grecian mind. Not only indeed were we the first to open the mine, but by us it has been principally worked; for among the numerous publications which now exist on the Hellenic remains, by far the greatest number, and indisputably the most correct, are by our countrymen, and were brought out in this country. It required, however, a generation for the effects of ignorance and prejudice in some, and imperfect knowledge in others, to wear away, before the beneficial effects of the Greek style could be obvious in our structures. The works of the Adams, who were contemporaries of and immediate successors to Sir William Chambers, evince a taste for the beauties of Greek architecture, but a very imperfect knowledge indeed of the means of reproducing them. The architects who have had the direction of our principal works during the first quarter of this century had the disadvantage of being pupils of those who were themselves, as we have shown, incompetent to appreciate the Greek style; and at a time too when the state of Europe shut up all access to the remains of Greece and Rome; so that no great improvement could perhaps be expected from them. When they shall have passed away, it is to be hoped that we shall find a new class, some of whom, indeed, are already before the world, who, having received their education since peace has opened the Continent, are prepared by the actual contemplation and study of the works of Egypt, Greece, Rome, and Italy, in all their varieties, to form new and pleasing combinations of their beauties, adapted to our wants,—to produce what may equal, if not surpass them all. The structures of Egypt may show how to arrange large masses harmoniously and effectively; those of Greece and Rome how to impart grace and dignity; and the structures of Italy how the materials of ancient architecture may be moulded to modern uses, while at the same time they give practical warning of what may result from the abuse of the most obvious principles of the art.

The difference between the representations of the Athenian antiquities by Stuart and his colleague, and the misrepresentations of them by Le Roy, appears to have opened the eyes of the world to those of ancient Rome, to see if they too had not been dealt with unjustly; for of late years much more correct delineations of them have appeared than those of Palladio and Desgodetz,—delineations of them as they exist, exhibiting the spirit of the originals, and not warped to the Vitruvian precepts, and thereby stripped of their best quality, truth. The excavation of the ancient cities of Herculaneum and Pompeii has opened to us much interesting matter, and some that is instructive: their ruins too have the advantage of being correctly delineated; so that we are at this time in possession of more knowledge of the architecture of the ancients, acquired in a few years by the actual examination of its relics, than our predecessors of the last generation were, after talking, and writing, and reading Vitruvius about it, for nearly four centuries.

It is an argument in proof of the classical beauty of the Pointed style, that when the eyes of men were opened to the perfections of Greek architecture, they began to discover its merits also. Pointed architecture, under the opprobrious name Gothic, had long been a subject of discussion among antiquaries; that is, essays were written by them to prove how the Pointed arch originated, but none appreciated its beauties. Our Pointed cathedrals and churches were, after the example of Inigo Jones, ruth-

History. lessly barbarized in repairing and fitting up. If an architect were employed to do any thing in or to one of them, he appears to have thought it incumbent on him to convert it to the doctrines of his own faith—to Italicize it. Deans and Chapters for the most part intrusted their commissions to country masons and plasterers, who also operated according to the laws of the "five orders." About the middle of the 18th century one Batty Langley endeavoured to draw the attention of the world to Pointed architecture, by reducing it to rules, and dividing it into orders. Fortunately he was only laughed at, and both he and the book he published on the subject were soon forgotten. One of the first men in rank and influence of his time, in matters of taste particularly, Horace Walpole, *patronized* Pointed architecture, but ineffectually. He had himself neither taste nor feeling to appreciate its beauties, as his Strawberry Hill clearly evinces; so that his patronage of it must have been the effect of mere whim, or a wish to lead a fashion. Delineations were indeed put forth from time to time, but generally so rude and imperfect, that, like M. le Roy to Greek architecture, they did more harm than good. The Society of Antiquaries, however, at length took up the subject, engaged Mr John Carter, an ardent and judicious admirer of our national architecture, and commenced the publication of a series of splendid volumes, containing engravings of its best specimens, from drawings and admeasurements by him. The "Antiquities of Athens" had already done much to dispossess men of their prejudices, by showing that Greek architecture, though neither Vitruvian nor Palladian, was nevertheless beautiful; and the great work of the Society of Antiquaries did the same for Pointed architecture. Since the death of Mr Carter, our native style has been beautifully illustrated, in a series of valuable works by Mr Britton, and elucidated in detailed "specimens," by Mr Pugin, a French gentleman but an English artist, and by a great variety of other useful and excellent publications; so that, at the present time, the Pointed style, too, is studied and understood, and not a few of our architects are now competent, not only to be intrusted with the repairs and restorations of the ancient structures, but also to originate new ones, which may rival all but their prototypes in beauty.

We have now, in this part of the subject, only to add a few remarks on the improvement which has taken place in domestic architecture, since men have begun to consider their own comfort and happiness of as much importance to them as the splendour of their religious edifices. The exhumated city of Pompeii has very clearly proved, that notwithstanding the extent and general beauty of the public buildings of the Romans, the houses of the commonalty were exceedingly plain and confined, while those of the higher classes, though internally elegant, were externally unpretending. The rooms were small and badly arranged, imperfectly secluded from the public gaze, and quite exposed to the inmates; pervious alike to the summer's heat and winter's cold. Indeed, the house of a Roman gentleman presents a very convenient model for a prison, but without many of the comforts which in modern times are thought necessary even in such places. Of this, however, we shall treat more in detail when we come to consider Roman architecture as a style. It has been stated as probable, that the use of wooden floors, and the consequent power of making additional stories without enormously thick walls, arose during the middle ages. That improvement, together with the use of glass for windows, gives an air of comfort and convenience to the earliest domestic structures of modern times, of which the ancients could have had no idea; but the latter were deficient in elegance, though indeed the use of windows tended to the introduction of external architectural decoration. With learning and civilization came refinement and luxury, and men began, though at a great distance, to imitate in their houses what they found of beautiful and splendid in the churches and monasteries. The exclusion, by glass windows, of currents of cold air, which carried the smoke off to the funnel in the roof of a hall or large room, when the fire was exposed in the middle of it, led to the invention and use of chimneys, which should convey it away without occupying the room at all. This is more particularly applicable to the colder countries north of the Alps, and it is in them that domestic building is best understood, and is best applied to produce comfort and convenience. Not that the *Palazzi* of Italy are not generally more pretending in their external architecture than the town mansions of this country; but they are deficient in those internal arrangements which tend to produce the greatest possible advantages—which, indeed, promote the enjoyments of domestic life.

In consequence of the refinements which now pervade the manners, habits, and customs of civilized life, and civilization having extended itself from the noble and the learned through almost the whole social system, men are no longer contented to admire the beauty and magnificence of public edifices, whether ecclesiastical or civil, and to witness the splendour and elegance of the palaces and mansions of the wealthy; but all are anxious to see in their own habitations that degree of decoration and beauty which they find so productive of pleasure and pleasurable emotions. Thus architecture is no longer confined to the temples of the Divinity and the palaces of the great, but its beauties are sought everywhere. In every edifice whose inhabitant has been fitted by education and habit to appreciate and enjoy the charm which arises from symmetry of form, beauty of proportion, and elegance of detail, the aid of architectural art is required.

Of Egyptian Structures.

The architecture of ancient Egypt is characterized by the boldness and magnitude of its parts, and the almost monotonous uniformity which pervades its features. The existing monuments of Egyptian architecture consist for the most part of temples and pyramids. Obelisks are generally found in connection with the former, so that perhaps they can only be considered as belonging to them, and not as distinct architectural works, or the sphinxes and other things of a similar nature must be considered as such also. Neither can the hypogea or excavations be correctly described as belonging to architecture, though they bear many of its features, and were perhaps the antitypes of regular architectural combinations.

The pyramids are almost solid masses of masonry, whose bases are squares, and whose inclined sides are nearly equilateral triangles: some of them are truncated, and some run up to a point. They are generally much injured on the surface by long exposure, so that it is impossible to say whether any of them were considered finished while in steps or receding courses, or if the angles were either filled up or worked off, to make smooth surfaces on the exterior. Some of them not only were made plain by working off, but remain so still; whilst others bear no indication of ever having been finished in that manner. In one existing example, that of the great southern pyramid of Dashour, the angles of the receding courses have been wrought off; and it is singular that the blocks of stone are not laid in horizontal courses, but at an angle inclined to the base; nor are its sides carried up to the top in one continued plane, but at about two thirds from the base they incline towards each other under a more obtuse angle.

It has been imagined, but not determined, that most of

Egyptian Structures. them have natural hills, either of earth or stone, for cores, or rather that hills have been cut to the shape, and built over with large courses of stone to give them the appearance of being solid masonry. If this be the case, the chambers and the passages to them, which have been discovered in some of the pyramids, have been carefully built around to have the appearance of being left in the construction, which is not very probable. Another suggestion, to account in some measure for the immense quantity of matter in them, is, that they are actually cut in living rock to a considerable height, and built above. This may be the case with regard to those which are of the stone the place affords; but some of them are of foreign material, externally at least, and of consequence cannot have been hewn in the native rock. More consistent with the genius of Egyptian undertakings, but hardly more probable is it, that the pyramids include or cover some such constructions as the labyrinth beyond Lake Mœris, spoken of by Herodotus, according to the suggestion we have made in another place, or chambers of some kind which may have been the depositories of the arcana of Egyptian learning and science. Such indeed is the immense extent of some of these extraordinary monuments of human industry and human folly, that no suggestion with regard to them can be considered wild, as they afford full scope for the imagination, without presenting any thing to support or refute any theory that may be applied to them.

The Egyptian temples, without possessing that entire uniformity of plan which those of the Greeks do, are very similar in arrangement and manner. The larger and more perfect structures do not externally present the appearance of being columned, a boundary wall or peribolus girding the whole, and preventing the view of any part of the interior, except perhaps the towering magnificence of some inner pylones; of the lofty tops of an extraordinary avenue of columns, with their superimposed terrace; of the tapering obelisks which occupy, at times, some of the courts; or of a dense mass of structure, which is the body of the temple itself, inclosing the thickly columned halls. The immense magnitude of these edifices may perhaps have made them independent, in their perfect state, of considerations which have weight in architectural composition at the present time, and on which indeed its harmony depends. The various portions of the same temple differ in size and proportion; and being intermingled, the cornices of the lower abut indefinitely against the walls of the higher parts, while the latter are not at all in accordance among themselves.

Plate LII. The structure we produce to exemplify Egyptian architecture, though not, according to M. Champollion, one of the Pharaonic monuments, is perfectly characteristic of the style and arrangement of Egyptian temples, and is a more regular specimen than any other possessing the national peculiarities. It is known as the temple of Apollinopolis Magna, or of Edfou, in Upper Egypt, on the banks of the Nile, between Thebes and the first cataracts.

The plan of the inclosure behind the propylæa is a long parallelogram, the moles or propylæa themselves forming another across one of its ends. The grand entrance to the great court of the temple is by a doorway between the moles, to which there may have been folding gates, as the notches for their hinges are still to be seen. Small chambers, right and left of the entrance, and in the core of the propylæa, were probably for the porters or guards of the temple: a staircase remains on each side, which leads to other chambers at different heights. To furnish these with light and air, loop-holes have been cut through the external walls, which disfigure the front of the structure. The court-yard, cloister, or vestibule, has on three of its sides a colonnade, against the wall of the peribolus, forming a covered gallery. This, and the gradual ascent by corded steps to the great portico or pronaos, will be better understood by reference to the plan and section. The pronaos, or covered portico, consists of three rows of six columns each, parallel and equidistant, except in the middle, where the intercolumniation is greater, because of the passage through. The front row of columns is closed by a sort of breast-work or dado, extending to nearly half their height, in which moreover they are half-imbedded; and in the central opening a peculiar doorway is formed, consisting of piers, with the lintel and cornice over them cut through, as exhibited in the elevation of the portico. From the pronaos another doorway leads to an atrium or inner vestibule, consisting of three rows of smaller columns, with four in each, distributed as those of the pronaos are. Beyond this vestibule there are sundry close rooms and cells, with passages and staircases, whose intention is not obvious. The insulated chamber within the sixth door was most probably the adytum or inmost sanctuary, which may be supposed, in an Egyptian temple, to have contained a presentment of the divinity: the rest is inexplicable.

Egyptian Structures. Figs. 3 & 4. Fig. 2.

In many cases the temples are without the peribolus and propylæa, the edifice consisting of no more than the pronaos and the parts beyond it; and in others, particularly in those of Thebes, this arrangement is doubled, and there are two pairs of the colossal moles, the second being placed where the pronaos is in this, and another open court or second vestibule intervening them and the portico. In these the central line across the courts is formed by a covered avenue of columns, of much larger size than ordinary; and the galleries around are of double rows of columns instead of one row with the walls, as in this case. The obelisks marked in the plan, and indicated in the section, before the propylæa, occupy the situation in which they are generally found, though they do not exist with this example. Colossal sedent figures are sometimes found before the piers of the gateway; and from them, as a base, a long avenue of sphinxes is frequently found ranged like an alley or avenue of trees from a mansion to the park-gate, straight or winding, as the case may require.

Fig. 3. The longitudinal section of the edifice shows the relative heights of the various parts, and the mode of constructing the soffits or ceilings, which are of the same material of which the walls and columnar ordinances are composed: this is in some cases granite, and in others freestone. Fig. 2. The elevation of the pronaos shows also a transverse section of the colonnades and peribolus. It displays most of the general features of Egyptian columnar architecture; the unbroken continuity of outline, the pyramidal tendency of the composition, and the boldness and breadth of every part. The good taste with which the interspaces of the columns are covered may be remarked. Panels standing between the columns would have had a very ill effect, both internally and externally; and if a continued screen had been made, the effect would be still worse, as the columns must then have appeared from the outside absurdly short; but as it is, their height is perfectly obvious, and their form is rendered clear by the contrast of light and shade occasioned by the projection of the panels, which would not exist if they had been detailed between the columns. Figs. 6 & 7. The lotus ornament at the foot of the panels is particularly simple and elegant; and nothing can be more graceful and effective than the cyma above their cornice, which is singularly enriched with ibis mummy-cases. The jambs forming a false doorway in the central interspace, are a blemish in the composition; and they injure it very much by the abruptness of their form, and their want of harmony with any thing else in it. It may be remarked, that the effect of the front generally is that

Egyptian Structures.

of an excavation rather than of a structure, the end piers and entablature having a unity of purpose, which leads to the idea that the rest was similar, or the whole at first a plain wall afterwards pierced and carved into its present form. This view of it would support the supposition that the excavations or hypogea are the antitypes of columnar architecture.

Fig. 1. The front elevation of the moles or propylæa, with the grand entrance between them, is peculiarly Egyptian; and very little variety is discoverable between the earliest and latest specimens of this species of structure. It is an object that must be seen to be appreciated; simplicity and an inherent impressiveness in the pyramidal tendency are all on which it has to depend for effect, except magnitude, which alone would certainly make no agreeable impression on the mind. The projecting fillet and coving which form a cornice to the structures, though large and bold, appear small and inefficient when compared with the bulk they crown; and there is nothing particularly striking in the torus which marks the lateral outline and separates the straight line of the front from the circular of the cornice. Neither are they dependent for their effect on the sculpture, for their appearance is as impressive at such a distance as to make the latter indistinct, as when they are seen near at hand. The effect of the sculptures and hieroglyphics generally on Egyptian architecture is to enrich the surfaces, but not to interfere with the general form of a structure, or even with the forms of its minor parts.

A portion of the portico is given on a larger scale, to show more clearly the forms and arrangement of Egyptian columnar composition. The shaft of the column in this example is perfectly cylindrical. It rests on a square step, or continued stylobate, without the intervention of a plinth or base of any kind; and has no regular vertical channelling or enrichment, such as fluting, but is marked horizontally with series of grooves, and inscribed with hieroglyphics. The capitals are of different sizes and forms in the same ordinance. In this example the capital, exclusive of its receding abacus, is about one diameter of the column in height. Its outline is that of the cyma, with a reversed ovalo fillet above, and its enrichment consists principally of lotus flowers. The capital of the column next to this, in the front line, is much taller, differently formed, and ornamented with palm leaves; the third is of the same size and outline as the first, but differently ornamented; and the corresponding columns on the other side of the centre have capitals corresponding with these, each to its fellow, in the arrangement. Above the capital there is a square block or receding abacus, which has the effect of a deepening of the entablature, instead of a covering of the columns when the capitals spread, as in this case. In the earlier Egyptian examples, however, in which the columns are swollen, and diminished in two unequal lengths, the result is different, and the form and size of the abacus appear perfectly consistent. The height of this column and its capital, without the abacus, is six diameters. The entablature consists of an architrave and cornice, there being no equivalent for the frieze of a Greek entablature, unless the coving be so considered, in which case the cornice becomes a mere shelf. The architrave, including the torus, is about three quarters of a diameter in height, which is half that of the whole entablature. The architrave itself is in this example sculptured in low relief, but otherwise plain. The torus, which returns and runs down the angles of the building, is gracefully banded, something like the manner in which the fasces are represented in Roman works. The coving is divided into compartments by vertical flutes, which have been thought to be the origin of triglyphs in a Doric frieze; but these are arranged without reference to the columns, and are in other respects so totally different from them as to give but little weight to the suggestion. The compartments are beautifully enriched with hieroglyphics, except in the centre, where a winged globe is sculptured, surmounting another on the architrave, as shown in the elevation of the pronaos. The crowning tablet or fillet is quite plain and unornamented. Angular roofs are unknown in ancient Egyptian buildings, and consequently pediments are unknown in its architecture.

Fig. 5. Fig. 2. Plate LI. Fig. 7. Plate LII. Fig. 5.

Of the style of architecture used in the domestic edifices of the Egyptians we can give no idea, as no documents remain by which it may be known; neither can we judge of it by analogy from what we know of that of other nations of antiquity, for no direct analogy exists between the styles of their still existing structures. Indeed the Romans are the only people, before the Christian era, of whose domestic architecture we know anything with certainty; and the advantage they possessed over their predecessors in their knowledge of the use of the arch was so great, for that purpose especially, that theirs affords no certain index to that of the Greeks even, and none whatever to that of the Egyptians.

Hindoo Structures.

Of Hindoo Structures.

From local circumstances, structures in India are exposed to rapid destruction as soon as they lose the protecting power of man; and thus the absence of any positive architectural works in that country which can be determined to be of high antiquity may be partly accounted for. But religious intolerance and devastating war have conspired together to aid natural causes in the destruction of the ancient edifices of the Hindoos. Whatever of antiquity fell in the route of that ruthless conqueror Mahmood of Ghizni, in his twelve expeditions into India, was defaced or destroyed; and those structures in the more remote parts, impervious to his march, either want data to pronounce on their antiquity, or, when they possess any, it is in a character still unintelligible to the learned. But there are some to which tradition—and this we should not altogether reject—assigns a date beyond the age of Alexander; and we understand that the unity of style of these warrants the assumption of immense priority for them to all now existing in Gangetic India. It is from Rajpootana that we may yet look for developments of the ancient architecture of the Hindoos; a field of great magnitude, only just begun to be explored, and still remaining undelineated. Extensive excavations, however, of much greater magnitude even than those of Egypt, and, it is presumed, of at least equal antiquity, are found in various parts of India; and they may be supposed to bear some resemblance to their contemporaneous structures, of which, most likely, they were either the representations or the originals. But we thus arrive only at the style: the composition and arrangement of structures cannot be deduced from the hypogea; for though these latter in Egypt agree in style with the architecture, they would not suggest the other particulars.

The most common Hindoo pagoda of the present day is composed of a rectangular mass, surmounted by a graduated truncated pyramid. That this species of structure is of very considerable antiquity, may be concluded from the fact, that every thing in its composition and arrangement is determined by immutable precepts of a religious nature. This was ascertained by Colonel Tod, the learned annalist of Central India, from a man to whom the precept had descended with his profession from his ancestors through more than forty generations.

These kinds of evidence, however, though interesting, are not conclusive; and we must consent, for the present at least, to remain in ignorance of the Hindoo archi-

tecture of the early ages, to which our inquiry is more immediately directed. The splendid works of the Moslem conquerors of that country bear no relation whatever to its indigenous architecture.

Of Grecian Structures.

As no nation has ever equalled the Egyptians in the extent and magnitude of their architectural monuments, neither have the Greeks been surpassed in the exquisite beauty of form and proportion which theirs possess. Extreme simplicity and perfect harmony pervade every part of a Greek structure; and to the evanescence of the finer spirit of these qualities may be referred the difficulty—for great difficulty certainly exists—of applying Grecian architecture to modern practice. The national style, or Doric Order, is in every respect the most distinguished and the most intractable. The voluted Ionic being more complicated, is more plastic; and the foliated Corinthian, from its still greater divergence from Doric simplicity and harmony, is the most easily moulded to various purposes. Unfortunately nothing remains from which we might acquire a knowledge of the practice of the Greeks themselves in the architecture of domestic and general structures; but it may be inferred from some existing edifices, particularly the Choragic monuments, that the Doric columnar style was not used by them except for the temples of the gods and some of their accessories. But whether this arose—if the feeling really did exist—from the sanctity of its character, in consequence of that appropriation, or from the difficulty of moulding it to general purposes, cannot be determined. It is very certain, however, that the few structures which do exist of Greek origin, not of a religious character, are either Ionic or Corinthian, or a mixture of one of them with some of the features of the Doric; and in all Greece and the Grecian colonies, except Ionia, there are very few examples of religious edifices not of the Doric order, and none which are of the Corinthian.

We have already given our reasons for mistrusting the descriptions of ancient writers on architectural subjects; and when they merely make reference to different parts of a structure, without pretending to describe, in the absence of examples or models they must be unintelligible, and therefore no more valuable to the architectural antiquary than those of the writers, whom existing specimens of what they profess to describe prove to have been totally ignorant of their subject. We shall therefore not attempt to develope what does not exist, either from inferences to be drawn from Homer and others, from the professional dicta of Vitruvius, or from the description of Pausanias; but confine ourselves to the remains of the structures themselves of the Greeks, which are actually before our eyes, for the elucidation and exemplification of the Grecian style.

Like the architecture of Egypt, that of Greece is known to us principally by means of its sacred monuments, and from them is deduced almost all we know of its principles. The Doric temples of the Greeks are uniform in plan, and differ only in arrangement and proportion, as they are of greater or less size; for every part depends on the same modulus. If the dimensions of a single column, and the proportion the entablature shall bear to it, were given to two individuals acquainted with the style, with directions to compose a hexastyle peripteral temple, or one of any other description, they would produce designs exactly similar in size, arrangement, features, and general proportions, differing only, if at all, in the relative proportions of minor parts, and slightly perhaps in the contour of some of the mouldings. This can only be the case with the Doric, and it arises from the intercolumniation being determined by the arrangement of the frieze with triglyphs and metopes; the frieze bearing a certain proportion in the entablature to the diameter of the column, and so on, in such a manner that the most perfect harmony is preserved between every part. Thus, in the example, the column is so many of its diameters in height; it diminishes gradually from the base upwards, with a slightly convexed tendency or swelling downwards; and is superimposed by a capital proportioned to it, and coming within its height. The entablature is so many diameters high also, and is divided, according to slightly varying proportions, into three parts—architrave, frieze, and cornice. A triglyph bearing a certain proportion to the diameter of the column is drawn immediately over its centre; the metope is then set off equal to the height of the frieze; another triglyph is drawn, which hangs over the void; then a metope as before; and a second triglyph, the centre of which is the central line for another column; and so on to the number required, which, in a front, will be four, six, eight, or ten columns, as the case may be, the temple being tetrastyle, hexastyle, octastyle, or decastyle; and on the flanks twice the number of those on the front and one more, counting the columns on the angles both ways. Thus a hexastyle temple will have thirteen columns on each flank, an octastyle seventeen, and so on. It must be observed, however, that to ease the columns at the angles, they are not placed so that the triglyph over them shall impend their centre as the others, but are set in towards the next columns so far that a line let fall from the outer edge of the triglyph will touch the circumferential line of the column at the base, or at its greatest diameter. It has been generally thought that the object in this disposition was to bring the triglyph to the extreme angle, to obviate the necessity of a half-metope there; and many imitators have puzzled themselves to no avail to effect it without contracting the intercolumniation or elongating the first metope; though it is perfectly obvious that the intention of the Greek architects was to ease the columns in those important situations of a part of their burden, and for no such purpose as Vitruvius and his disciples have thought. Indeed, this has been a problem to the whole school, which their master proposed, and which they have settled only by putting a half-metope beyond the outer triglyph; thus preserving the intercolumniation equal, but rendering the quoins more infirm, or perhaps less stable, than the Greek architects judiciously thought they should be. Besides contracting the intercolumniation, the Greeks also made the corner columns a little larger than the rest, thus counteracting in every way the danger that might accrue to them, or to the structure through them, from their exposed and partly unconnected situation. The graduated pyramidal stylobate on which the structure rests also bears a certain proportion to the standard which is the measure of all the rest; and so every part is determined by the capacity of the sustaining power. Though the Doric order thus possesses, as it were, a self-proportioning power, which will secure harmony in its composition under any circumstances, yet skill and taste in the architect are necessary to determine, in every instance, the number of diameters the column shall have in height, and according to that assign the height of the entablature. For these two points in proportioning, and for appropriate detail and enrichment, he may, without servility, refer to the ancient examples; with the confidence, moreover, that in availing himself of their beauties he acquires the power of producing an object that shall be itself beautiful, while he can avoid being a mere copyist in the adaptation and arrangement of the materials of his composition, as well as in the selection

Plate LIII. Figs. 1 & 4.

Plate LIV. Fig. 3. Plate LIII. Fig. 3. Fig. 1 & 4.

Grecian Structures.

of them. We cannot discover that the elevation of the pediment depended so immediately on the common standard, though in the best examples the tympanum will be found to be about one diameter and a half in height.

The Ionic and Corinthian, or Voluted and Foliated orders, do not possess that innate principle of harmony which pervades the Doric, and therefore they are, as styles, less perfect, and depend more on factitious combinations. The Greek compositions of Ionic and Corinthian are of such consummate beauty in every particular, that their examples appear perfect, and may therefore be taken as models for study, in preference to the rules which have been laid down for those orders, without a knowledge of these exemplifications. With a consciousness of their inferior capacity to produce grand and harmonious effects in such arrangements as their temples require, the Greeks never applied either the Ionic or the Corinthian peripterally, and, as far as we have certain knowledge, only the latter in prostyles. Whether the Ionians did or did not, cannot be satisfactorily ascertained, as their temples are in every case so much destroyed, that it is impossible, at least without more care and attention than they have yet received, to make out satisfactorily what their plans were. In the Ionic and Corinthian orders, the proportions of the various parts are generally made dependent on the diameter of the column, as in the Doric; but the intercolumniations, and consequently the general proportions, of a composition, are not determined by the column and its accessories according to their capacity, but must be left to the taste and skill of the architect, as well as the columnar proportions themselves. This gave rise to the rules referred to, which are laid down by Vitruvius, for what he calls the "Five Sorts of Edifices," or, more correctly, species of intercolumniation. They are pycnostyle, systyle, diastyle, aræostyle, and eustyle, to each of which a fixed space is assigned. Architects will, however, act more wisely in judging for themselves, by reference to the best models of antiquity, what proportion constitutes an *Eustyle* intercolumniation, according to the application of his ordinance, than by attending to such irrational dogmas as are contained in that classification.

The temples of the Greeks are described, according to their external arrangement, as being either in antis, prostyle, amphiprostyle, peripteral, pseudo-peripteral, dipteral, or pseudo-dipteral; and internally, as cleithral or hypæthral. The columnar arrangement in antis is not common in Greek architecture, though there are examples of it, generally of the Doric order. The inner porticoes or pronaoi of peripteral temples are for the most part placed in antis, as may be seen by reference to the examples, in which columns stand between the antæ. The Ionic temples of Athens are the principal examples of the simple prostyle. They may be called apteral, if it be necessary to distinguish them from peripteral, as the latter are prostylar; but the former term alone is sufficient. Neither does Greek architecture present more than one example, and that is at Athens also, of an amphiprostyle, except in the same peripteral structures, which are also amphiprostylar. Almost all the Doric temples are peripteral, and being peripteral, they are, as a matter of course, amphiprostylar, as we have just remarked; so that the former term alone is used in describing an edifice of that kind, with the numeral which expresses the number of columns in each of its prostyles. There is but one known example of Greek antiquity of a pseudo-peripteral temple, and that is the gigantic fane of Jupiter Olympius at Agrigentum in Sicily. It is not even prostylar, for the columns on its fronts are attached, as well as those on its flanks. The dipteral arrangement is found at Selinus, in an octastyle temple; and in some cases the porticoes of peripteral temples have a pseudo-dipteral projection, though no perfect example of the pseudo-dipteros exists.

Plate LIII. Fig. 2, and Plate LIV. Fig. 2.

Most of the temples of the Greeks were cleithral; those to the inferior and demi-gods were invariably so. The fanes of the supreme divinity were almost as invariably hypæthral, and frequently those of other superior gods were of the latter description also. The Doric order was never used by the Greeks in mere prostyles; consequently there is no Doric temple of the tetrastyle arrangement, for it is incompatible with the peripteral, the tetrastyle examples which do exist being all Ionic.[1] With very few exceptions, all the Doric temples of the Greeks are hexastyle. Their queen, however, the unmatched Parthenon, is octastyle; and the pseudo-peripteral fane of Jupiter Olympius at Agrigentum, just referred to, presents the singular arrangement, heptastyle. No example exists in Greek architecture of a portico of more than eight columns, except the mis-shapen monument called the Basilica at Pæstum, the Thersites of its style, be so considered, and that has a front of nine columns, or an enneastyle arrangement.

Plate L.

It may be here remarked, in support of the opinion we have given as to the authority of Vitruvius, that, according to him, peripteral temples have on each flank twice the number of intercolumniations they have in front; thus giving to a hexastyle eleven, to an octastyle fifteen columns, and so on, whereas in the Greek temples this is never the case, for they always have more. The best examples have two, some have only one, but many have three, and in one instance there are four intercolumniations more in flank than in front. Again, he limits the internal hypæthral arrangement to those structures which are externally decastyle and dipteral, though an example, he says, existed in Greece of an octastyle hypæthros, and that was a Roman structure. Now, the Parthenon is an octastyle hypæthros, but all the other hypæthral temples, both in Greece and her colonies, are hexastyles, except perhaps the octastyle dipteral at Selinus; and there is no evidence in existence that the Greeks ever constructed a decastyle dipteral temple.

A Greek temple, whose columnar arrangement is simply in antis, whether distyle or tetrastyle, consists of pronaos and naos or cella. A tetraprostyle may have behind it a pronaos and naos. An amphiprostyle has, in addition to the preceding, a posticum, but is not understood to have a second entrance. The porticoes of a peripteral temple are distinguished as the porticus and posticum, and the lateral ambulatories are incorrectly called peristyles. It may indeed be here suggested, that as the admixture of Latin with Greek terms in the description of a Grecian edifice cannot be approved of, it would perhaps be better to apply the term *stoa* to the colonnaded platform or ambitus altogether, and distinguish the various parts of it by the addition of English adjectives: or the common term portico would be quite as well with front, back, and side or lateral, prefixed, as the case may be. Within the back and front stoas or porticoes, then, a peripteral temple has similar arrangements in antis, which are relatively termed the pronaos and opisthodomus, with an entrance only from the former; unless there should exist, as there does in the Parthenon, a room or chamber within the opisthodomus, supposed to be the treasury, when a door opens into it from the latter. Besides these,

Plate LIV. Fig. 3.

Plate LIII Fig. 3.

[1] Athens itself containing a Doric tetraprostyle, may seem to contradict this; but it must be recollected that we have already said (page 442), that in speaking of Greek architecture, we exclude all the examples, even in Greece itself, which were executed under the Roman dominion, for they bear the Roman impress; and that is one of them.

Grecian Structures.

a Greek temple of the most ramified description consists only of a cell, in those which are cleithral; and of a naos, which is divided into nave and aisles, to use modern ecclesiastical terms, in an hypæthral temple.

The only pure Greek architectural works that remain to us, and of which we have certain information, besides temples, are, it has been already stated, propylæa, choragic monuments, and theatres. The Propylæum, or Propylæa, as applied to the Acropolis of Athens, is the entrance or gateway through the wall of the peribolus into it. It consists of a Doric hexaprostyle portico internally, with a very singular arrangement of its columns, the central intercolumniation being ditriglyph. This was done probably to allow a certain procession to pass, which would have been incommoded by a narrower space. Within the portico there is a deep recess, similar to the pronaos in a temple, but without columns in antis; a wall pierced with five doorways corresponding to the intercolumniations of the portico, close the entrance; and beyond it is a vestibule, divided into three parts by two rows of three Ionic columns, and forming an outer portico, fronted externally by a hexaprostyle exactly similar to that on the outside. Right and left of it, and setting out about one intercolumniation of the portico from its end columns, at right angles, are two small triastyle porticoes in antis, with chambers behind them. These have been called temples, but most probably they were nothing more than porters' lodges or guard-houses. The whole structure, though extremely elegant, and possessing many beauties, is not a good architectural composition: the unequal intercolumniation detracts from its simplicity and harmony. The use of Ionic columns in a Doric ordinance is equally objectionable; and their elevation from the floor of the portico on insulated pedestals is even worse, though their intention is obvious; and without raising them, the ceiling might have been too low, or they must have been made taller.[1] The uneven style of the small temples or lodges is not pleasing, even though they be taken as flank and not as front compositions; and, moreover, their entablature abuts indefinitely against the walls of the larger structure, both internally and externally, to the total destruction of the harmony of the general composition. Indeed the unequal heights of the entablature of the greater ordinance involves a fault, if there were not something to prevent them from being seen in the same view, which it requires more than all the beauties of detail and harmony of proportion to countervail.

Plate LVI. Fig. 1 & 2. The choragic monument of Lysicrates, vulgarly called the Lantern of Demosthenes, at Athens, is a small structure, consisting of an elegant rusticated quadrangular basement or podium, which is more than two fifths of the whole height, surmounted by a cyclostyle of six Corinthian columns, attached to, and projecting rather more than one half from, a wall which perfects the cylinder up to the top of their shafts, where it forms a stand for tripods the height of the capitals. A characteristic entablature rests on the columns, and receives a tholus or dome, which is richly ornamented, and terminates in a foliated and heliced acroterium. To this Stuart has added dolphins as supporters, and has placed on the summit a tripod, which was the prize in the choragic festival; thus completing perhaps the most beautiful composition in its style ever executed. In Vitruvian language the arrangement of this edifice would be called monopteral; but it is more correctly cyclostylar, or, perhaps, because of the wall or core, it may be termed a pseudo or attached cyclostyle. The basement of this monument is eminently bold and simple, admirably proportioned to the rest of the structure, and harmonizing perfectly with it. The columnar ordinance is the only perfect specimen of the style in existence of pure Greek origin, and it has never been surpassed, perhaps not equalled, in beauty elsewhere. The most exquisite harmony reigns throughout its composition: it is simple without being poor, and rich without being meretricious; and the same applies to the superimposed tripod and its supports. Fig. 3.

Totally different in style and arrangement, and far inferior in merit, is the choragic monument of Thrasyllus. It bears, however, the impress of the Grecian mind. This composition is merely a front to a cave, consisting of three pilasters proportioned and moulded like Doric antæ, and supporting an entablature similar in style, but too shallow to harmonize with them. Above the entablature there is an attic or parapet, divided into three compartments horizontally. The two external form tablets with a cornice or impost on them, and the central is composed of three receding courses, on the summit of which is seated a draped human figure, whether male or female, in its mutilated state is not determinable. The entablature, instead of triglyphs in the frieze, has laurel wreaths; and it would appear as if the absence of the triglyph had deranged the whole composition. The two outer pilasters are of good proportion, and the architrave is well proportioned to them; but the frieze and cornice are both too narrow, and the spaces between the pilasters, equivalent to intercolumniations, are too wide. The third pilaster, itself inharmonious, is absurdly narrow, being narrower than the others; and, standing immediately under the statue, evidently to support it, its meagreness is the more obvious and striking. In spite of all this, the general outline of the structure is simple and pleasing, the detail is elegant, and the execution spirited and effective. This little monument is, however, a proof that the Greeks were not so excellent in architectural compositions at all times, as in the self-composing Doric temples, and in the choragic monument of Lysicrates; and to this evidence may be added that of the triple temple in the Acropolis of Athens. It consists of an Ionic hexaprostyle in front, resting on a bold, continuous, and well-proportioned stylobate, and forming the entrance to a parallelogramic cella, but, from all that has yet been discovered, without a pronaos in antis. The back-front consists of four columns like those of the portico, attached in antis; and the flanks are broad and bold, crowned by the well-proportioned and chaste entablature, with the enriched congeries of mouldings and running ornament of the antæ under it. In the absence of a pronaos to give depth to the portico, the composition was defective, but otherwise simple and harmonious. It was, however, completely spoiled by the attachment of a tetraprostyle to one of its sides, Ionic certainly, like that in front, but not only in a different manner, but of a different size; beautiful in itself, but a blot on the main building, with which it harmonizes in no one particular, being altogether lower; for the apex of its pediment only reaches to the cornice of the former. This and the Caryatidean portico are omitted in the example. In a similar situation, against the other side is attached a similar arrangement of Caryatides, a tetraprostyle of female figures raised on a lofty basement, and yet not reaching to the entablature of the main building,—according in no one particular either with it or with the portico on the other side, and altogether forming the most heterogeneous Plate LV.

[1] An editorial note in the new edition of *The Antiquities of Athens* says that "they are incorrectly mounted on pedestals" in Stuart and Revett's *Restoration*. This structure cannot perhaps fairly be judged of, until its site and remains shall have been examined without the jealous supervision of a Turkish governor.

Grecian Structures.

and inharmonious combination imaginable. Yet the two Ionic porticoes are the most beautiful examples of their Order in existence, and perhaps, it might be added, that were ever executed,—arranged in the finest proportion, and with the most exquisite details and enrichments. The Caryatidean frontispiece, also, for more it cannot be called, is full of architectural beauties, though it is most injudiciously collocated.

The theatres of the Greeks, it has been already intimated, present but little to interest in the view we are taking of architecture. They were not structures, but excavations; and whatever decoration they may have received to make them objects of interest externally, is, in every known example, entirely gone; and attempts to restore them from their remains as now existing, aided by all the information to be derived from ancient writers, would be futile, in the absence of a knowledge of the Greek style of art obtained from some other source. And as no existing example of the Greek theatre furnishes matter for architectural illustration, we should gain no information in furtherance of our present subject by treating of it here.

The division of the columnar architecture of the Greeks and Romans into orders by the Italian architects of the fifteenth century, according to the laws of Vitruvius, and the universal reception of that mode of arranging it, almost impose upon us the necessity of adopting the same course, and laying down a standard or model for each. But instead of so doing, we think it better to give each school separately, and describe the general features of the orders as they occur in the works of each,—pointing out, moreover, the varieties that exist, and prevent the monotony consequent on restricted forms and proportions. We retain, too, the term " Order," and the names in general use, without consenting to the propriety of either the one or the other; for if it be judicious to divide Greek and Roman columnar architecture into orders, there can be no reason why Egyptian, Hindoo, Persian, or any other style, should not be classed in a similar manner. Moreover, there is nothing in any one " order" that, were it not for custom, would not be thought as fitting in any other as in that to which it may belong. The Greeks did not hesitate to put triglyphs in the frieze of an entablature whose columns were fillet-fluted and had foliated capitals, as some ruins at Pæstum attest. As to names, the Doric might, as we have said, be called Corinthian with more propriety; the Ionic, Samian; and the Corinthian, Athenian; referring to the oldest known examples of each. The term Style would be more correct than Order, as it would indicate the column as the feature referred to, without conveying the idea of fixed rules; and architectural works into which columns do not enter need not be constrained to admit the arrangement of some Order in the composition, proportion, and detail of its various parts. In naming, too, the Doric might be called the Greek sacred or triglyphed style; the Ionic, the Voluted style; and the Corinthian, the Foliated; thus admitting any varieties of combination which could be expressed as composites of the voluted and foliated, or of the foliated and triglyphed, as the case might be.

An Order, according to Mr Gwilt, is " an assemblage of parts, consisting of a base, shaft, capital, architrave, frieze, and cornice, whose several services requiring some distinction in strength, have been contrived or designed in five several species,...each of which has its ornaments as well as general fabric proportioned to its strength and character." Perrault says that an order may be defined " a rule for the proportion of columns, and for the form of certain parts which belong to them, according to the different proportions which they have." We would have it understood to be a species of columnar arrangement, differing in its forms and general proportions, and in some leading features, from any other. Greek columnar architecture may thus be divided into the three arrangements or orders, Doric, Ionic, and Corinthian, which form its classes or styles. In considering them, however, it is necessary to discharge the mind of all the absurdities of the Italo-Vitruvian school about the proportions of the human figure being applied to columns, whether virile, matronal, or virginal; about the trunks of trees and rafters' feet; whether Doric columns should not have bases because men have feet, or that Ionic columns should have them because women wore sandals; that the guttæ in a Doric entablature should be conical, and not pyramidal, because they are to look like drops of water; that sculls, furies, thunderbolts, and daggers may be used to enrich a Doric frieze, but that spears, and swords, and stars, and garters may not;—these, with the thousand other puerilities of the *Cinquecentists*, whether Italian, French, or English,—whether acquired from the writings of Palladio and Scamozzi, of Perrault and Leclerc, or of Wotton and Chambers,—must be forgotten, and the greater or less degree of beauty resulting from this or that mode of arrangement and detail alone attended to.

Grecian Doric.

Not to induce the idea that the quoted examples of the antique should be imitated to the line and letter, but rather in spirit, we shall speak of the proportions of their various parts generally; though it must at the same time be understood that much of the beauty of a columnar composition depends on its minutiæ: still it is not necessary that these minutiæ should be mere repetitions of an original; it is in the spirit of the antique models that excellence is to be sought, and not in crude rules for their reproduction.

Of the Grecian Doric.

This order may be divided into three parts, Stylobate, Column, and Entablature. The stylobate is from two thirds to a whole diameter of the column in height, in three equal courses, which recede gradually the one above from the one below it, and on the floor or upper step the column rests. That graduation, it may be remarked, does not appear to have been made by the ancients to facilitate the access to the floor of the stoa or portico, but on the principle of the spreading footings of a wall, to give both real and apparent firmness to the structure, both of which it does in an eminent degree.

The column varies in different examples from four to six diameters in height, of which the capital, including the necking, is rather less than half a diameter: in those cases in which a necking does not exist, the capital itself occupies nearly the same proportion. The shaft diminishes in a slightly curved line, called entasis, from its base or inferior diameter upwards to the hypotrachelium, leaving it at that place, or at the superior diameter, from two thirds to four fifths of the lower or inferior, which latter is the diameter always intended when the term is used as a measure of proportion. The capital consists of a necking, an echinus or ovalo, and an abacus; the necking is about one fifth of the height of the capital, and the other two members equally divide the remaining four fifths: when there is no necking, the ovalo occupies the greater proportion of the whole height. The abacus is a square tablet, whose sides are rather more than the inferior diameter of the column. The corbelling of the ovalo adapts it to both the diminished head of the shaft and the extended abacus, flowing into the one, and forming a bed for the other by means of a graceful cyma-reversa; but its lower part is encircled by three or four rings or annulets, which are variously formed in different examples,

Plate LI. Fig. 10. Plate LIII. Fig. 4 & 9. Plate LIV. Fig. 4.

Fig. 6 & 7.

Grecian Doric.

and which are the means of giving the echinus form to the great moulding, although it is, as we have said, part of a cyma-reversa. The shaft is divided generally into twenty flutes; but there are several examples with sixteen, and there is one with twenty-four. The flutes are sometimes segments of circles, sometimes semiellipses, and sometimes eccentric curves. They always meet in an arris or edge, and follow the entasis and diminution of the column up through the hypotrachelium to the annulets, under which they finish, sometimes with a straight and sometimes with a curved head. At the base they detail on the pavement or floor of the stylobate.

Plate LIII. Fig. 12. Plate LIV. Fig. 8 & 14.

The third part of the order, the entablature, ranges in various examples from one diameter and three quarters to rather more than two diameters in height, of which about four fifths is nearly equally divided between the architrave and frieze, and the cornice occupies the remaining one fifth: this is in some cases exactly the distribution of the entablature. The architrave is in one broad face, four fifths, and sometimes five sixths of its whole height; and the remaining fifth or sixth is given to a projecting continuous fillet called the tænia, which occupies one half the space, and a regula or small lintel attached to it, in lengths equal to the breadth of the triglyphs above in the frieze. From the regulæ six small cylindrical drops called guttæ depend. There are examples to the contrary, but it may be taken as a general rule, that the architrave is not in the same vertical line with the upper face of the shaft, or its circumferential line, at the superior diameter, but is projected nearly so much as to impend the line or face of the column at the base. The frieze, vertically, is plain about six sevenths of its whole height, and is bounded above by a fascia, slightly projecting from it, which occupies the remaining seventh. Horizontally, however, it is divided into triglyphs and metopes, which regulate the intercolumniations in the manner that has been already described; the former being nearly a semidiameter in width, and the latter the space interposed between two triglyphs, generally an exact square, its breadth being equal to the whole height of the frieze, including the fascia. This latter breaks round the triglyphs horizontally, and is a little increased in depth on them. Each glyph, of which there are two whole ones and two halves to every tablet, is one fifth of the width of the whole, and the interglyphs are each one seventh of the whole tablet or triglyph. The glyphs detail on the tænia of the architrave, but are variously finished above. In some examples they are nearly square-headed, with the angles rounded off; in others the heads are regular curves, from a flat segment to a semiellipsis. The semiglyphs are finished above in a manner peculiar to themselves, with a turn or drop; but hardly two examples correspond in that particular. The tablets in which the glyphs are cut are vertical to the face of the architrave, the metopes recede from them like sunk panels; these are often charged with sculptures, and indeed almost appear contrived to receive them. The third and crowning part of the entablature, the cornice, in what may be considered the best examples, projects from the face of the triglyphs and architrave about its own height. Vertically, it is divided into four equal parts, one of which is given to a square projecting fillet at the top, with a small congeries of mouldings, different, and differently proportioned to each other, in various examples. Two other parts are given to the corona, and the remaining fourth to a narrow sunk face below it, with the mutules and their guttæ. These latter form the soffit or planceer of the cornice, which is not horizontal or at right angles to the vertical face of the entablature generally, but is cut up inwards at an angle of about 80°. The width of the mutules themselves is regulated by that of the triglyphs over which they are placed, to which it is exactly equal. They are ornamented each with three rows of six small cylinders, similar to those which depend from the regulæ under the triglyphs and on the architrave. There is twice the number of mutules that there is of triglyphs, one of the former being placed over every metope also in the manner the examples indicate.

Grecian Doric.

This completes the Greek Doric Order according to the generally received sense of the term; but there are other parts necessary to it. In the front or on the ends of a temple, or over a portico, a pediment is placed. Its intention is obviously to inclose the ends of the roof, but it forms no less a part of the architectural composition. In reason, it should be raised as much as the roof required; but when the span is great that would be unsightly; and reference appears to have been made to the common standard of proportion, as the pediments of most Doric temples are found to be about one diameter and a half in height at the apex of the tympanum, which in a hexastyle arrangement makes an angle at the base of about 14°, and in an octastyle about $12\frac{1}{2}$°. The pediment is covered by the cornice, without its mutules, rising from the point of its crowning fillet, so that no part of it is repeated in profile. Another moulding, however, is superimposed: sometimes this is an ovalo with a fillet over it, and sometimes a cymatium. It varies much in its proportion to the cornice, but in the best examples it is about one half the depth of the latter without its mutules. Ornaments of various kinds, statues or foliage, are believed to have been placed on the apices and at the feet of pediments as acroteria. Of these, however, we have no actual remains; but indications of the plinths or blocks which may have received them exist, and such things appear represented in ancient coins and medallions. The tympana of pediments are well known as receptacles of ornamental sculpture. On the flank of a Doric temple, the cornice supported a row of ornamented tiles called antefixæ. These formed a rich and appropriate ornament, but they rather belonged to the roof than to the columnar arrangement or order. The antefixæ covered the ends of the joint-tiles as the pediments did those of the roofs; and corresponding ornaments called stelai rose out of the apices of the joint-tiles, forming a highly enriched ridge.

Plate LIV Fig. 1.

Plate LIII. Fig. 1.

A secondary Doric order arises in the disposition of a Grecian temple, from the columns of the pronaos and the inner part of the external entablature continued and repeated. Of this the frieze is generally without triglyphs, though there may be regulæ and guttæ on the architrave. The fascia of the frieze is either moulded or enriched on the face; and, instead of a cornice, the beams of the ceiling are laid at equal intervals to support sunk panels or coffers, in which there may be flowers or other enrichments.

Fig. 9.

Propriety in the composition and arrangement of antæ is as necessary to the perfection of the Doric order as to that of the columnar ordinance itself, especially if the latter be *in antis*. Slight projections are made on the end and side faces of a wall, so as to form a species of pilaster, whose front shall be nearly equal to the diameter of the columns to which it is attached, exactly equal indeed to the soffit of the entablature, whose faces have been described as impending the circumferential line of the column at a little above its base. This rests on the stylobate in the same manner as the columns do, with sometimes a small continuous moulding as a base; and its capital is a congeries of mouldings, about the depth of the abacus, with a plain fascia corresponding to the ovalo of the columnar capital. The entablature of the order to which it is attached rests on it, and, continuing along the flank of the building, is received by a similar combination at the other end. These, it may be remarked, were never diminished or fluted,

Fig. 2, 3, & 10; and Pl. LIV. Fig. 2, 3, & 9.

Grecian Ionic.

being projections from and upon the ends and faces of walls, they could not be diminished without involving an absurdity; and fluting on a straight surface must be productive of monotony, as the flutes can only project a series of equal and parallel shadows. Not so, however, with columns, on whose rotund surface fluting produces a beautiful variety of light and shade in all their gradations, which it could not possess without that enrichment; for on a plain column neither are the lights so bright nor the shadows so dark as in the former case, nor are they so finely diffused over the whole surface in the one as in the other.

In the only example which occurs in the ancient architectural remains of attached Doric columns,—that of the pseudo-peripteral temple of Jupiter Olympius at Agrigentum—the stylobate is peculiarly arranged. The upper gradus is grooved, and detailed round the columns and along the walls between them; and a congeries of vertically arranged mouldings and fillets rests on it, and receives the base of the column.

Such are the materials of which the Greeks composed their beautiful temples, the manner of whose composition has been already described. Of their effect, however, it is impossible to form a competent idea without seeing one. And whence, it may be asked, does their interest arise? Pl. L. From their simplicity and harmony;—simplicity, in the long unbroken lines which bound their forms, and the breadth and boldness of every part; such as the lines of the entablature and stylobate, the breadth of the corona, of the architrave, of the abaci, of the capitals, and of their ovalos also; in the defined form of the columns, and the breadth of the members of the stylobate;—harmony, in the evident fitness of every part to all the rest. The entablature, though massive, is fully upborne by the columns, whose spreading abaci receive it, and transmit the weight downwards by the shafts, which rest on a horizontal and spreading basement; the magnitude of every part, as we have before had occasion to remark, being determined by the capacity of the sustaining power. Besides graceful and elegant outline, and simple and harmonious forms, these structures exhibit a bewitching variety of light and shade, arising from the judicious contour and arrangement of mouldings, every one of which is rendered effective,—by the fluting of the columns and the peculiar form of the columnar capital, whose broad, square abacus projects a deep shadow on the bold ovalo, which mingles it with reflections, and produces on itself almost every variety. The play of light and shade, again, about the insulated columns, is strongly relieved and corrected by the deep shadows on the walls behind them; and in the fronts, where the inner columns appear, the effect is enchanting. For all the highest effects which architecture is capable of producing, a Greek peripteral temple of the Doric order is perhaps unrivalled.

Of the Grecian Ionic.

Not less Hellenic in its detail than the national Doric is the graceful and elegant style called the Ionic, whose proportions and peculiarities we take from the perfect examples of the Athenian Acropolis.

Pl. LV. This order may also be considered in three similar parts, Stylobate, Column, and Entablature. The stylobate is in three receding equal courses or steps, whose total height is from four fifths of to a whole diameter. The column, consisting of base, shaft, and capital, is rather more than nine diameters in height, of which the base is two fifths of a diameter; and the capital, including the hypotrachelium, is in one case three fourths, and in the other seven eighths of a diameter high. The base consists of a congeries of mouldings, extending gradually from a diameter and a third to a diameter and a half, and its height is in three nearly equal parts, two equal fillets separating them. The lowest, a torus, rests on the top of the stylobate or floor of the portico, a fillet divides that from a scotia, a second fillet intervenes the scotia and a second torus, and a third fillet bases the apophyge or escape of the shaft. The upper torus of the base is, in one example, fillet-fluted horizontally; and, in the other, the same member is enriched with the guilochos. The shaft diminishes with entasis from its lower or whole diameter, to above five sixths of it immediately under the hypotrachelium. It is fluted with twenty-four flutes and alternating fillets, which follow the diminution and entasis of the column. The flutes in plan are nearly semiellipses, and they finish at both ends with the same curve: a fillet is in thickness nearly one fourth the width of a flute. The difference in the height of the capital is in the length of the necking, which in one case is separated from the head of the shaft by a carved bead, and in the other by a plain fillet. Above the necking, a height of about one third of a diameter is occupied by a congeries of three spreading or corbelling mouldings, a bead, an ovalo, and a torus, which are all appropriately carved. On these rests the parallelogramic block, on whose faces are the volutes, and whose ends are concaved into what is technically termed a bolster, to connect them. This part is about one third of a diameter in height, and includes a rectilinear abacus, whose edges are moulded to an ovalo, and carved with the egg and tongue ornament. The volutes are three fifths of a diameter in depth, and extend in front to one diameter and a half; and they are nearly a semidiameter apart. The flowing lines which connect the volutes can only be understood by reference to the example. The Fig. 5. bolsters are fluted vertically, with alternate fillets, on Fig. 12. which are carved beads. An ornament composed of the honeysuckle with tendrils encircles the necking of the column. It must be remarked, that as the capitals are parallelcgramic, and present but two similar fronts, to preserve the appearance of volutes externally on all sides, the capitals of those columns which occupy the external angles of porticoes are differently arranged. The outer Fig. 16. volute is bent out at an angle of 45°, and volutes are put on the end or side-front of the capital also, the outer one being the other side of the angular volute of the front. To suit the angle internally, the two volutes of the inner face are placed at right angles to each other: this is, however, at best but an awkward expedient, and need not be employed when a portico projects only one intercolumniation.

The entablature, which is rather more than two diameters in height, is also divided into three parts—architrave, Fig. 5. frieze, and cornice—which may be proportioned by dividing the whole height into five parts, four of which, as in the Doric, may be again equally divided between the architrave and frieze. The cornice, however, in the examples referred to, does not occupy one fifth of the entablature; but if it had a fillet over the upper moulding, which it appears to want, that would be just its proportion. If the architrave be divided into nine parts, seven of them may be given to three equal fascias, which slightly project the one before the other; the first or lowest, which is vertical to the circumferential line of the inferior diameter, being covered by the second, and the second by the third. The remaining two ninths form a band of mouldings corbelling a broad fillet, which separates the architrave from the frieze: these mouldings are enriched. The frieze, which does not project quite so much as the lowest fascia of the architrave, is, in the Athenian examples, quite plain; but it may be enriched with foliage, or made the receptacle of sculpture in low relief. The cornice projects from the face of the frieze rather more than

Grecian Ionic.

as much as its whole height, and is composed of bed mouldings, a corona, and crown mouldings. The first are a carved bead and carved cyma-reversa, the former of which only occupies a portion of the height of the cornice, as the planceer is cut up inwards in the manner represented by dotted lines in the example, to a sufficient depth for it; the crown mouldings, which consist of a carved ovalo above a carved bead, are rather more than one fourth of the whole cornice; and the corona occupies the rest of its height, except that small portion given to the bead of the bed mould. A fillet above the crown mouldings, as already intimated, is certainly necessary to complete the order and receive the antefixæ, as described in the Doric, for the flank of a temple.

Fig. 1 & 2. The pediments in the examples of Ionic are rather flatter than in those of the Doric, the angle made by the covering cornice with the base being, in a hexastyle, less than 14°. A vertical fillet, with a small moulding, equal in depth to the two crown mouldings of the cornice, covers them in the pediment, in the place of the cyma-recta or ovalo used in the Doric order. The intercolumniation differs in these examples; in the one it is two diameters, and in the other three diameters and one-sixth.

A much greater variety is found in the composition of the Ionic than of the Doric order. Indeed the examples of the Athenian Acropolis alone have neckings; in all the others the shaft runs up to the corbelled mouldings, which bed the block of the volutes, and the flutes finish under them. Neither have they a torus in that congeries, but a bead and ovalo alone, which latter makes an inconvenient projection under the pendent lines that connect the volutes, and thus the capital is not more than half a diameter in height.

The Asiatic or the truly Ionian examples of this order are far inferior to those referred to. Their bases are differently, and certainly less elegantly composed. They are without hypotrachelia, as may have been inferred; they want the torus in the capital; and, in most cases, instead of flowing, pendent lines, they have straight lines connecting the volutes. Their entablatures are not so finely proportioned, nor so delicately executed. The coronas want breadth, and the bed moulds of the cornice are as much too heavy as those of Athens are perhaps too light. Indeed, upon the whole, they have more of the grossness of Roman architecture than of the delicacy and elegance of Grecian, though the Ionian examples are supposed to be the models of those of Athens.

Fig. 10. The width of the antæ of the Ionic order is determined, as in the Doric, by the soffit of the entablature; and it will, of course, be exactly the same as, or rather less than, the inferior diameter of the column. It is slightly raised, too, from the face of the wall at the ends of which it stands. The base of the antæ is, in one of the two examples of the Acropolis, a little deeper than that of the column, having a small projecting moulding between the lower torus and the floor; and the lower torus itself is reeded. In the other example there is no difference in the form and proportion of the antæ and columnar bases, but both the tori are fluted horizontally, with beaded fillets between the flutes. The antæ cap consists of a congeries of corbelling mouldings, nearly one third of a diameter in height. It is divided into three nearly equal parts, the lowest of which is composed of a bead and an ovalo; the second of another bead and a cyma-reversa, all carved; and the third of a plain flat cavetto, with a narrow fillet and small crowning cyma-reversa, forming an abacus. The necking is like that of the capital, and is enriched in the

Fig. 3. same manner. The cap or cornice thus formed breaks round the projection of the antæ, and is continued along the wall under the entablature the whole length of the building, or till it is impeded by some other construction, and the base is continued in like manner.

Grecian Corinthian.

Fig. 2. Attached columns have the voluted capital, but their base is that of the antæ; and it is detailed round them and along the wall to which they belong, as with the antæ. It must be remembered, however, that the attached columns in the triple temple are about one ninth less in diameter than those which are insulated, though they are similar in other respects, and have the same entablature.

The back of the triple temple, between the attached columns, presents the only example in Greek architecture of windows. These are rather more than twice their width in height, and are narrower at the top than at the bottom. They rest on a broad, bold sill, which is equal in depth to two sixths of the opening, and are surrounded externally by a congeries of mouldings, which, with a plain fascia, constitute an architrave. This architrave is one fourth the opening in width; it diminishes with the window, and in the same proportion, and is returned above in two knees, which are made vertical to its extreme point at the base.

Of the Grecian Corinthian.

Plate LVI. Fig. 1. The importance which the Greeks attached to a graduated stylobate, and the necessity of giving it a relevant proportion in a columnar ordinance, are evinced in the only example of this order which remains to us of Grecian origin. Unlike the Doric and Ionic in its application, which is in temples of rectangular form, whose whole height they occupy, this is attached to a small circular structure, resting on a lofty square basement; and yet, like those orders, it has a stylobate in receding courses, and in plan, too, corresponding with the arrangement of the Fig. 2. columns, and not with that of the substructure; in this too offering further proof that the stylobate was considered a part of the columnar ordinance. Thus the Corinthian Fig. 1 & 3. order also consists of stylobate, column, and entablature. The stylobate is rather more than a diameter in height, and is divided into three parts, but not equally, in consequence, it is probable, of the peculiar position of the ordinance. The two lower grades have vertical faces, are of equal depth, and occupy three-fourths of the whole height; whilst the third step occupies the remaining fourth and is moulded on the edge, in exquisite harmony with the more ornate style, of which it forms a part. Like the column of the Ionic order, that of the Corinthian consists of base, shaft, and capital: it is ten diameters in height. The base is rather more than one third of a diameter high, and is composed of a torus and fillet, which are nearly two fifths of its whole height; a scotia and another similar fillet, rather less than the former; and a second torus or reversed ovalo, one fifth the height of the base, on which rests a third fillet basing the apophyge of the shaft. The extent or diameter of the base, at the lower torus, is rather more than one diameter and a half. The shaft diminishes with entasis to five sixths of its diameter at the hypotrachelium, and, like that of the Ionic order, has twenty-four flutes and fillets. The flutes are semiellipses, so deep as nearly to approach semicircles: they finish in the apophyge at the foot of the shaft, in the same manner and form; and at the head they terminate in leaves, to which the fillets are stalks. The fillets are rather more than one fourth the width of the flutes. The hypotrachelium is a simple channel or groove immediately under the capital. The capital itself is a diameter and rather more than one third in height: its core is a perfect cylinder, in bulk rather less than the superior diameter of the shaft. This is banded by a row of water leaves, whose profile is a flat cavetto, one sixth of the whole height, and another of leaves of the acanthus, with flowered buttons attaching them to the cylin-

Grecian Corinthian. der. These latter have the contour of a cyma-recta, and are twice the height of the last, or one third of the whole capital. Rather more than another third is occupied by helices and tendrils, which latter support a honeysuckle against the middle of the abacus; and the abacus itself, resting on and covering the whole mass, is but little more than one seventh of the whole height. This member in plan can only be described as a square whose angles are cut off at 45°, and whose sides are deeply concaved. In profile it consists of a narrow fillet, an elliptical cavetto or reversed scotia, and another fillet surmounted by a small ovalo, or rather a moulding whose profile is the quadrant of an ellipsis.

The entablature of this order is two diameters and two sevenths in height. It also consists of architrave, frieze, and cornice, of which the first occupies one tenth more than a third, the second rather more than as much less than that proportion, and the cornice is so much more again above one third. The architrave is divided, like that of the Ionic order, into three equal fascias, which occupy all but one sixth of its whole height, and that is given to a corbelled band, consisting of a bead, cyma-reversa, and fillet, separating the two members of the entablature. The fascias of the architrave, it must be remarked, are not perpendicular, but incline inwards, so that their lower angles are all in the same vertical line, which impends the surface of the shaft about one third of its height from the base. The frieze is one plain band, slightly inclining inwards, like the fascias of the architrave, and slightly projected beyond them: in this example it is enriched with sculptures. The cornice consists of a deep congeries of bed mouldings, and a corona, with the accustomed small crown mouldings and fillet. Its extreme projection is nearly equal to its whole height: of this the bed-mouldings project about two fifths. As in the Ionic cornice, additional height is given to the bed-moulds, by undercutting the planceer. In this case, the undercutting extends to nearly one-fourth the height of the corona. One-sixth the height of the cornice is given to a flat bead and an ovalo, which are immediately above the frieze, and which base a broad dentilled member that occupies more than one-fourth of the whole cornice. This is surmounted by a listel or broad fillet, above which is a cymarecta, whose narrow fillet nearly reaches the horizontal plane of the planceer, and separates it from a cyma-reversa that beds the superimposed projecting corona. This latter is only three eighths of the whole cornice, and nearly one of the three is given to the ovalo and fillet, the bed-moulds alone occupying five eighths. The cornice is surmounted by a cut fascia supporting honeysuckle antefixæ, which may indeed be taken as a part of the order, as the solitary example in question presents it. This, however, we know, from the Doric and Ionic structures, to be a modification of the flank ornament of temples; and we may suppose from analogy, that if used in a portico, the cornice of this order would have a cyma-recta to crown it on the inclined side of the pediment. The intercolumniation of this example is two diameters and one third.

Of Corinthian antæ we have no examples, nor indeed have we of insulated columns; but as we find in the Ionic examples quoted, that the attached columns are less in proportion to the entablature than those which are insulated, we may conclude that it would be the same with this; thus reducing the entablature to two diameters, the ordinary average of that part in Greek columnar architecture.

Of the Caryatides, or Caryatic Order.

Fig. 4, 5, & 6. The solecism in architecture of which we have now to speak has but the one existing example in the works of the Greeks, to which we have already referred. It is the third portion of the triple temple in the Athenian Acropolis, and is a projection from the flank of the principal Ionic structure, formed by a stereobatic dado raised on the stylobate and antæ-base mouldings of it, with a surbase consisting of a carved bead and carved ovalo covered by a broad listel, with a narrow projecting fillet above it. Caryatic Order. On this rests a square plinth, which bases a draped female figure, on the head of which there is imposed a circular moulded block, with a deep rectangular abacus, two thirds of whose face is vertical, and the other third is a cavetto, fillet, and small cyma-reversa. The stereobate, including the moulded base of the temple, is about three fourths the height of the statue-pillar with its base and capital. The entablature is rather less than two fifths of the same, but it consists of architrave and cornice alone, between which parts the height is nearly equally divided. Rather more than one fifth of the former is given to a carved bead and carved cyma-reversa, with the flat, plain cavetto and fillet which they support; the other four-fifths is divided nearly equally into three fascias, of which the third or upper one has a fraction more than the other two, and is studded with plain circular tablets, whose diameter is five sixths of its depth. The cornice consists of bed-mouldings, corona, and crown mouldings. Two fifths of its whole height is given to the bed-mould, to which one seventh of that may be added for the portion cut up in the planceer. Half that increased height is occupied by a dentilled member, and the other half by a broad plain fillet, a carved bead, carved cyma-reversa, and a narrow fillet above it. The remaining three fifths of the whole cornice being again divided into five parts, rather less than two of them is given to the corona; a little more than one to a plain cyma-reversa and fillet, of which the latter is the wider; and of the rest a carved ovalo occupies five sevenths, and a listel or crowning fillet, with a carved bead on it, the other two. A pier, pilaster, or antæ, projects from the wall of the greater temple, and receives the end of the entablature behind the inner figure; for the projection is of two statues and their interspaces. It does not, however, rest on the stereobate, but runs down to the base-mouldings of the temple, the dado and surbase abutting against it. The antæ is capped by a congeries of carved mouldings, which support a narrow cavetto and fillet: the height of the cap is half the diameter of the antæ. There is also a hypotrachelium, consisting of a carved bead and the honeysuckle ornament, occupying about one third of a diameter in height. This Caryatidean portico displays very clearly the arrangement of the ceiling, with its coffers or cassoons. Internally the architrave is plain two thirds of its height; of the remaining third rather more than one half is a plain, slightly projected, fascia; the other half is occupied by a carved bead and ovalo. In the absence of a frieze, the ceiling rests on this, and is divided by carved beads into panels, which are deeply coffered, and diminished by three horizontal moulded fascias.

Of Grecian Mouldings and Ornament.

Pl. LVII. Greek architecture is distinguished for nothing more than for the grace and beauty of its mouldings; and it may be remarked of them generally, that they are eccentric, and not regular curves. They must be drawn, for they cannot be described or struck; so that though they be called circular, or elliptical, it is seldom that they are really so: not but that they may be, but, if they are, it is evidently the result of chance, and not of design. Hence all attempts to give rules for striking mouldings are worse than useless, for they are injurious: the hand alone, directed by good taste, can adapt them to their purpose, and give them the spirit and feeling which render them effective and pleasing.

Grecian Mouldings.

The leading outline of Greek moulding is the gracefully flowing cyma. This will indeed be found to enter into the composition of almost every thing that diverges from a right line; and even combinations of mouldings are frequently made with this tendency. It is concave above and convex below, or the reverse; and though a long and but slightly flected line appears to connect two quickly-curving ends, it will always be found that the convexity and the concavity are in exactly the same curve, so that if the moulded surface were reversed, and the one made to assume the place, it would also have the appearance of the other, and the effect would be the same. It is, in fact, the Hogarthian line of beauty; and it is not a little singular that Hogarth, in his well-known *Analysis of Beauty*, although he did not know, and indeed could not have known, the contours of Greek architectural mouldings, has given the principle of them, and, under his line of beauty, has described many of the finest Greek forms. The Roman and Italian mouldings were called Greek in his day, and he assumed them to be so; but they evidently do not agree with his theory, whereas, in principle, the now well-known Greek forms do most completely.

The cyma-recta is generally found to be more upright and less deeply flected than the cyma-reversa; it is almost always the profile of enrichments on flat surfaces, of foliage, of the covering moulding of pediments, of the undercut or hooked mouldings in antæ-caps, the overhanging not affecting the general principle; and it pervades, as we have said, flected architectural lines generally, whether horizontal or vertical. The cyma-reversa has all the variety of inflection that its opposite possesses, but the line connecting its two ends is, for the most part, more horizontal, and its curves are deeper. It pervades many architectural combinations, but is most singularly evinced in the composition of the Greek Doric capital, which is a perfect cyma-reversa, with the ends slightly but sharply flected, as it flows out of the shaft below, and turns in under the abacus above. The obviousness of the former is prevented by the annulets which divide the cyma into an ovalo and a cavetto, but the principle is clear.[1] The cyma is the governing outline in the congeries of mouldings in bases also, as may be noticed in the Ionic and Corinthian examples quoted and referred to.

Pl. LIII. & LIV. Fig. 6 & 7.

Pl. LV. Fig. 5. Pl. LVI. Fig. 3.

An ovalo is but the upper half of a cyma-reversa, even when it is used as a distinct moulding, and unconnected with the waving form. The name expresses its apparent rather than its real tendency; for its contour is not that of an egg in any section, though the ornament which is carved on it, when used as a running moulding, is formed like an egg; and from that the moulding was named.

Pl. LVII.

The upper torus of a base forms, with the escape or apophyge of the shaft, a perfect cyma, and the scotia and lower torus do the same; so that the torus and scotia are referable to the same principle when in composition, and they are not found together except in the combination referred to.

The bead is an independent moulding, varying in contour; but it is generally the larger segment of a circle. It is used, however, sometimes to mask the waving form, and sometimes to separate it.

The cavetto, or simple hollow, is part of a cyma also, as we have shown; but it is also applied independently, to obviate a sharp angle, or to take from the formality of a vertical line, as in the abaci of Ionic antæ-caps. Its form, nevertheless, is not the segment of a circle, for the upper part of a cavetto is the most flected, and it falls below almost into a straight line.

Grecian Mouldings.

There is a hooked moulding common in Greek architecture, particularly in the Doric antæ-caps, which is technically called the hawk's-beak. It is a combination of curves which cannot be described in words; but it has been already referred to in speaking of the cyma-recta, which is brought into its composition.

Pl. LIII. Fig. 5 & 11 Pl. LIV. Fig. 5 & 10.

The cyma-recta is never found carved, or sunk within itself; but it sometimes has the honeysuckle, or other ornament of the kind, wrought on it in relief, particularly when used as the covering moulding—the cymatium—of a pediment. The enrichment of the cyma-reversa consists of a contrasted repetition of its own contour meeting in a broad point below, and joining by a circular line above, and making a sort of tongued or leafed ornament, whose surface is inflected horizontally also. Between the leaves a dart-formed tongue is wrought, extending from the circular flexure above to the bottom of the moulding, whose contour it takes in front alone. As this would not mitre or join well on the angles of the cyma, a honeysuckle is gracefully introduced in the manner shown in the example. This enrichment is not wrought in relief on the moulding, but is carved into it, so that the surfaces of the parts of the ornament alone retain the full outline of the cyma. The ovalo is enriched with what is called the egg and dart ornament. This will be best understood by reference to the example. Its angles also are made with a honeysuckle, and the inflections are made in the moulding itself. The torus is sometimes enriched with the interlaced ornament called the guilochos: this too is cut into the moulding itself. We have no Greek example of an enriched scotia, and from its form and position, which, to be effective, must be below the eye, it hardly seems susceptible of ornament which could operate beneficially. The bead is carved in spheres or slightly prolate spheroids, with two thin rings or buttons, dilated at their axes, placed vertically between them. A cavetto is not enriched at all, nor is the hawk's beak, except by painting, which does not appear to have been an uncommon mode of enriching mouldings among the Greeks; that is, the ornament was painted on the moulded surface instead of being carved into it. Fascias are also found enriched by painted running ornaments, such as the fret or meander, the honeysuckle, and the lotus. Sometimes plain colour was given to a member, to heighten the effect it was intended to produce. Ornaments were painted and gilt on the coffered panels of ceilings too.

Pl. LVII.

The few examples which exist of sculptured ornament on straight surfaces exhibit varieties of nearly the same combinations as those last mentioned,—the honeysuckle with the lotus, and sometimes a variety of itself on scrolls, either throwing out tendrils, or plain. This is found on the necking of the Ionic columns of the Athenian Acropolis, and on those of their antæ, and continuing along under the congeries of mouldings, as previously described. The varieties of foliage used in the enrichments of Greek architecture are few, and will be found generally exemplified in the Corinthian capital of the choragic monument of Lysicrates, and in the rich acroteral pedestal or stem of the same edifice, than which we possess no more elaborate specimen of foliated enrichment of the Greek school. There exist many specimens of architectural ornament on vases and fragments, in marble and terracotta,

Pl. LVI. Fig. 3. Fig. 1.

[1] The presence of the cyma in the Doric capital was, we believe, first pointed out by Mr T. L. Donaldson, in the supplementary volume to the new edition of Stuart's *Athens*, though the true contour of the cyma itself appears to have escaped that gentleman's attention.

Roman Structures.

in which human figures, both male and female, are composed, with a greater variety of foliage than is generally found in Greek architectural works; and many of the beautiful marble and bronze utensils discovered in Herculaneum and Pompeii have enrichments obviously of Greek origin, from which, as well as from the specimens of ornament on positive architectural monuments, we may judge of their productions generally, as well as acquire or imbibe somewhat of the fine taste which originated them.

It would be puerile to speculate on the domestic edifices of the Greeks any further than we have done, as we possess no genuine data on which to proceed. Their sacred structures have taught us their style of architecture; but for its application to general purposes we have no resource but to consult the Roman remains of the exhumated Campanian cities and other places, and gather from analogy what Greek domestic architecture was.

Of Roman Structures.

Temples and other public buildings.

With a treatise on Roman architecture by a Roman architect, in our hands, mere transcription would appear to be all that is necessary in writing on the subject. But finding the writer and existing specimens of the art at variance, we cannot help determining in favour of the superior authority of the latter; to which, therefore, we shall refer to elucidate Roman edifices and the Roman style, as we did to the Greek remains to elucidate the Grecian.

Though far inferior in simplicity and harmony to the columnar architecture of the Greeks, that of the Romans, whether derived from it or not, is evidently of the same family, and is distinguished by boldness of execution and elaborate profusion of ornament. The tastes of the two nations are exemplified in the Doric of the former and the Corinthian of the latter; the one a model of simple grandeur, perfect in its peculiar adaptation, but almost inapplicable to any other purpose; and the other, less refined, but more ornate, making up in extrinsic what it wants in intrinsic beauty—imperfect in every combination, but almost equally applicable to every purpose. As in Greece, so also in Rome, the noblest specimens of columnar architecture are in the temples of the divinity; but it does not appear that the Romans were in the habit of constructing them peripterally, as the Greeks so constantly did. There are indeed ruins which induce the belief that they at times built dipteral temples; but their common practice (as far as existing examples are authorities) was to make them pseudo-peripteral, or apteral and prostylar: of an amphiprostyle, even, we have not an example. It certainly is the custom to restore the ruined temples, whose remains are a few columns only, as if they had been peripteral; but it is done not only without sufficient authority, but against that which the more perfect structures present. The great projection, too, that the Romans gave their porticoes, is evidence that they were dependent entirely on themselves for effect; for they are generally projected three columns and their interspaces before the cella, which, however, has no pronaos with columns in antis; nor does it appear from existing remains that the Romans were accustomed to use that arrangement. Circular or peristylar temples are not uncommon in Roman architecture; and there are temples to which it can hardly be supposed that columns were ever attached: these are for the most part polygonal. Neither do the Romans appear ever to have constructed hypæthral temples with columns internally, as the Greeks did. Indeed it is a question whether all their temples were not cleithral; for it is not generally admitted that the Pantheon, which is hypæthral by the open eye of the dome, was originally a temple; and where the structures remain tolerably perfect, the ceilings and roofs appear to have been formed by arching from flank to flank, and thereby quite inclosing them.

Pl. LIII. & LIV.

Pl. LVIII.

The application of columns internally is most strikingly effective in the Pantheon, where they are arranged in front of niches, or deep recesses, composed with antæ to carry a crowning entablature round under an attic on which the cupola rests. No representation can convey even the most incompetent idea of the effect of this arrangement, to those who cannot gather it from the plan. A section presents only one compartment correctly; all the rest must of necessity be foreshortened. It is far otherwise with the temple of peace and the hall of the baths of Diocletian, in which columns stand before the piers to have the entablature broken over them. This, indeed, was the result, as we have before intimated, of the combination of columns with arches; and it is most clearly exemplified in those works which most probably originated the practice, and which are next in pretence to the temples:—these are the triumphal arches.

Pl. LX. Fig. 4 & 5

The Romans had not adopted the simple graduated stylobate of Greek columnar architecture in their temples, but made the access to their porticoes in front with thin steps, and built vertical stereobates along the flanks for the walls of the cella, or as stylobates, if there were attached columns. In applying a columnar arrangement to the triumphal arch, this lofty stylobate was taken also. The breadth of the opening prevented the columns from being placed equidistant; they were, therefore, coupled, the entablature was broken over them, and necessarily the stylobate was cut through, leaving mere attached pedestals to stilt the columns, so that the whole ordinance was deprived of every thing that could render it as a composition beautiful: its simplicity and harmony were entirely gone; and instead of giving a graceful character to the structure, it became a mere attached frontispiece, that could only deform it. As if conscious that the Corinthian was too beautiful to maltreat in such a manner, the Roman architects produced the hybrid, which has since been called the Composite order, to use in these compositions: in them, indeed, it is chiefly found; and if it were not evidently a mere deterioration of the Corinthian, it might with truth and propriety be called the Roman order.

Fig. 6, 7, & 8.

Fig. 10 & 11.

Pl. LIX. Ex. 2.

Coupled columns, broken and recessed entablatures and pedestals, and the Composite order, are among the greatest blemishes in Roman architecture; for the misformed and inappropriate abortions which have obtained the name of Ionic and Doric, in Roman works, are hardly to be attributed to the school, but to individuals of it, as they are of very infrequent occurrence, and generally appear only in works which are otherwise ungainly. Such are the amphitheatres, whose elliptical forms can never be graceful, and whose architecture was invariably the worst the time produced. The immense structure in Rome, which, from its magnitude, has been called the Colosseum, bears in relief the gross architectural solecism of columns in stories, which, moreover, have recessed stylobates and immense intercolumniations, with large arches in them, which again reduce the effect of the column still more, making the continuity of the entablatures themselves a fault, by their consequent infirmity. The architectural details of this structure are coarse and inelegant, plain without simplicity, and laboured without elegance. But internally these blemishes disappear, columns and arches piled upon columns and arches give way to the long continuous lines which graduated from the arena to the gallery, and must have produced as grand an effect as almost any object in architecture: its magnitude and ruined state produce the imposing effect so striking at the present time; but the mind can easily restore it, or it may

Ex. 3 & 4.

Pl. LX. Fig. 1.

Roman Structures.

be contemplated in miniature in the amphitheatre at Verona.

The most perfect specimens of the Roman theatre remaining are those of Pompeii and Herculaneum. Like those of the Greeks, they rest on the side of a hill; but instead of being hewn out of, they are built on it, as there is no rock out of which they might have been excavated. Their general form, however, is very similar to that of the Greek theatre, but they received a greater degree of architectural decoration than the latter was susceptible of. Of this the theatre of Marcellus in Rome is an example; for though otherwise destroyed, its external wall remains, and presents columnar ordinances, with intervening arches in stories, according to the vicious and inelegant practice of the Roman school. This, however, is on a plain, and presents external walls, which other examples do not so completely.

The baths of the Romans were structures of immense extent, and of splendid appearance internally. What their exteriors were we have no competent means of determining; fragments, however, give us reason to believe, that in architectural merit they did not surpass the exteriors of the amphitheatres. The walls internally were covered with stucco, and painted with foliage, figures of animals, and compositions, architectural landscape or history: the floors were of mosaic, laid in compartments, and variously ornamented: the ceilings were vaulted and stuccoed like the walls; sometimes they were enriched with coffered panels containing sculptured flowers or other architectural ornament, and sometimes they were merely painted with what are termed arabesques. Columnar ordinances do not appear to have been much used, and when they were, it was not always with good taste, as we have had occasion already to remark; though the structure called the Pantheon, which, with a great show of probability, is believed to have been a saloon in the baths, perhaps of Agrippa, on the contrary presents a beautiful adaptation of one. That the Pantheon was part of a more extended edifice, is very clear from its external form and appearance, which are unsightly in the extreme, presenting a mis-shapen and unfinished mass. Now, domed chambers are very common in the baths and palaces of the Romans. They are not only more effective than rectangular apartments, but were much more convenient in the absence of glass; for a small opening left in the apex lights and ventilates the domed saloon most completely, whilst the rain that could pass through it was necessarily small in quantity, and could be easily avoided by those walking on the floor. In rectangular vaults this could not be effected, so that rooms of that form depended on lateral openings for light and air, and were thereby exposed and uncomfortable. Again, there is a rectangular portico attached to the Pantheon, having no single feature in common with it, the former being a noble Corinthian octaprostyle of three intercolumniations projecting, with two others of antæ and pilasters behind; and the other a polygonal, bulbous mass of brickwork, much loftier than the portico, having cornices and blocking courses, too, none of which range with the entablature or any part of it. A conclusive argument, moreover, against the commonly received opinion, that the portico and the circular temple are an original composition, proving indeed that the former was an adaptation of what most likely had previously existed elsewhere in a different situation, and of course could not be intended for its present adjunct, is, that it now fronts north, and consequently the sun never shines full on it, so that it is in fact always in shadow; and that was never permitted even by the Romans in their original compositions; for two-thirds of the beauty of a portico, consisting in the beautiful play and contrast of light and shade it affords, are thus sacrificed. But in an after-appropriation, as we imagine in this case, it might have been, and clearly was done; probably through the ignorance or inattention of those who did it. If, then, the Pantheon, whose diameter is nearly 150 feet, was but an apartment—suppose the grand saloon or xystum—in the baths, the whole structure must have been immense; and if its proportions and internal architecture be taken, as they certainly may be, as a specimen of the style and manner of the interior of the edifice generally, we shall obtain a very high opinion of the magnificence of the Roman baths or thermæ. That they were adorned with admirable works of sculpture, too, is proved by the fact, that some of the noblest specimens of that art have been discovered in, and among the ruins of, the baths in Rome. It may be further remarked of the Pantheon, that its effect has been seriously injured since its original construction, by the removal of the columns from the recess opposite to the entrance, making the opening greater, fixing the columns before the antæ with the entablature broken round them, and turning an arch over the whole; thus destroying, as far as that part could affect it, the simplicity and perfect harmony of the primitive composition. The same bad taste which dictated that alteration affixed little pedimented excrescences, now used as altars, against the piers which alternate with the compartments of columns.

Fig. 2 & 3.

Fig. 4 & 5.

Palaces and villas

The still extensive remains of the villa of Adrian, near Tivoli, bespeak its original magnificence; and the architectural fragments with which the site even now abounds, though it has furnished specimens to almost every country in Europe, after having suffered the spoliation and destruction attending the incursions of barbarians and the lapse of so many centuries, attest its pristine beauty, and the fine taste of its imperial builder. This, however, furnishes no evidence that its exterior was attractive. Everything appears to have been directed to internal splendour and effect alone; and indeed all collateral evidence tends to the conclusion, that the exterior of Roman palaces and mansions was not heeded; being merely plain brick walls. This is the case at Pompeii, as we shall see; and the ruins of mansions in various parts of Italy, from that of Sallust on the Benacus or Lago di Garda, to those of other Roman nobles on the shores of the Bay of Baiæ, present no indications whatever that their exteriors were subjected to architectural decoration. The palace of Diocletian at Spalatro, and the splendid remains of Balbec and Palmyra, some of which perhaps belonged to secular structures, offer evidence to the contrary of this, if they are correctly restored in the works which treat of them; for they present in their elevations so many of the worst features of the Italian school, that there would be room for doubt, if views of the ruins did not help to justify the restorers. But this does not appear to have been the case in the earlier ages of the empire, when architecture among the Romans was in its best state. Notwithstanding the extent of the structure, and its general magnificence, however, the mouldings and ornaments in the interior of the villa of Adrian, though in themselves classical and elegant, are small, and have a general air of littleness, especially when compared with the apartments to which they belong;—not that the apartments are generally large, but they are for the most part lofty. The ceilings appear to have been formed by vaulting; there are no indications of windows, and none of stairs of any magnitude—so that the rooms must have been nearly if not quite open at one end, to admit light and air; and the probability is that there were no apartments above the ground floor, though it is likely enough that terraces formed on the vaulted roofs were used for the purposes of recreation and pleasure. The floors were of mosaic, several of

Roman Structures.

which are preserved entire in the Museum of the Vatican; and many fine specimens of ornamental sculpture in vases and candelabra, besides busts, statues, and groups in bronze, marble, porphyry, and granite, of various styles, the remains of the noble collection Adrian made during his progress through his extensive dominions, found among the ruins of the villa, are conserved in the same place.

The ruins of the palace of the Cæsars present no forms or arrangements from which it would be possible to form a rational notion of its original plan, still less of its general elevation, or indeed of the elevation of any part of it. Large vaulted apartments, with here and there a little stucco, sometimes moulded and sometimes plain or merely painted, and a few small unconnected chambers scattered up and down in a mountain of brick rubble, convey an exceedingly vague idea of a palace, or rather they are incompetent to convey an idea of a palace at all.

Roman streets.

If evidence were required to prove the futility of written descriptions of buildings when their general model is unknown, it would be enough to compare the house of a Roman gentleman in Pompeii with the various designs which have been made of the same thing from the descriptions and directions of Vitruvius, before the exhumation of that city. Their authors could only work upon the notion they had of laying out houses; and therefore the plans produced are those of ill-contrived modern residences, so arranged that they may present a uniform and architectural external elevation, which the Roman houses have not; with windows properly lighting every apartment, which are totally wanting in the latter; with staircases to upper stories that did not exist; with corridors and doors uniformly disposed, which was unheeded in laying out a Roman house. The Vitruvian restorers put columns wherever they could, whereas the Roman architects appear only to have put them where they could not avoid it. In dimensions, too, the former erred no less than in distribution; they thought none too extensive for a Roman domicile: but the apartments in Roman houses, wherever they are, are generally small, and in ordinary cases their whole site is exceedingly restricted. In proportioning the various parts, they adhered to rules the Romans never heeded; and applied the details of the architecture of temples and triumphal arches to domestic edifices, in whose composition the plasterer, painter, and mason, almost appear to have been the only architects!

Far inferior as Pompeii was to Rome in magnitude and splendour, there is no more reason for supposing that houses in the latter were so very differently arranged from those in the former that the same general description of them should not apply to both, than there would be for a future antiquary to hesitate in applying the plan of a Brighton or Bath house, which may be preserved, to a London mansion; for we know that in ordinary cases they nearly coincide. It is, too, a recorded fact, that wealthy Roman citizens had mansions at Pompeii and Herculaneum; and we have already stated that discoveries made of ordinary houses under the present level of Rome show them to be exactly like the more perfect ones of the Campanian city, except in their state of preservation; so that, "*parvis componere magna*," in Pompeii we may see the domestic as well as public architecture of ancient Rome.

The streets of Pompeii are very narrow, their average width being not more than twelve or fifteen feet; frequently they are not more than eight feet wide, and very few in any part exceed twenty. The principal excavated street in the city, that leading from the Forum to the gate towards Herculaneum and the street of the tombs, is, at the widest, twenty-three feet six inches, including two footways, each five feet wide. The streets are all paved with lava, and almost all have side pavements or footways, which, however, are for the most part so narrow, that, with few exceptions, two persons cannot pass on any of them. That the cars or carriages of the inhabitants could not pass each other in most of the streets, is proved by the wheel-ruts which have been worn on the stones, and the recesses made here and there for the purpose of passing. Their narrowness and inconvenience are aptly exemplified in London by the narrow lanes which come between St Paul's and Thames Street, about Doctors' Commons. The Forums, on the contrary, though not very spacious, are of regular forms, and have wide and convenient footways, completely colonnaded. In immediate connection with them are the theatres, the principal temples, the basilica, the courts of justice, and other public edifices: the amphitheatre is by itself, in an extreme angle of the city. The use of some of the buildings on one flank of the great Forum is not obvious: they are not arranged like temples, and indeed possess no peculiar character by which they may be distinguished: it is tolerably clear, however, from circumstances, that they were for the use of the public. The temples differ very little from the ordinary Roman structures of that description, but are generally inferior to them in the quality of the materials of which they are constructed, in the style of their architecture, and in the manner of its execution. The basilica is not unlike a modern church, it being a long rectangular edifice, having an arcaded porch at one end, being divided internally by rows of columns into nave and aisles, and having a columned recess at the west end of the nave for a tribunal. There are, however, no indications of windows, so that it was probably hypæthral, though that arrangement would have made the place very inconvenient for its purpose.

Pl. LXI. Fig. 1.

The streets of Pompeii are lined on either side with small cells, which served for shops of various kinds; and they are strikingly like the ordinary shops in towns in the south of Italy and in Sicily at the present time. Like these, too, there appear in very few cases to be accommodations in connection with the shops for the occupiers and their families, who must have lived elsewhere, as modern Italian shopkeepers very commonly do. They present no architectural decoration whatever; the fronts are merely plain stuccoed brick walls, with a large square opening in each, part of which is the door, and part the window, for lighting the place and showing the goods. Fig. 3.

Houses and domestic accommodations.

Whenever a private house or gentleman's mansion occurs in a good place for business, like the ground floor of many modern Italian noblemen's palaces, the street-front, or fronts, was entirely occupied with shops, a comparatively narrow entrance being preserved to the house in a convenient part between some two of them. The door to this is sometimes quite plain, but at times it is decorated with pilasters. When the site permitted such an arrangement, the entrance door being open, a passer by could look completely through the house to the garden, or, in the absence of a garden, to the extreme boundary wall, on which was painted a landscape or other picture. An arrangement, it may be observed, not unlike this, is common in some of the Italian cities at the present day; but the mansions being now built in stories, and the upper stories alone being occupied by the families, a merely pleasing effect is produced; whilst in the former, persons crossing from one apartment to another were exposed, and domestic privacy thus completely invaded to produce a pretty picture. Within the entrance passage, which may be from ten to twelve feet in depth, there is a vestibule or atrium, generally square, or nearly so, on which various rooms open, that vary in size from ten feet square to ten feet by twelve, or even twelve feet square: they

Roman Structures.

have doors only, and were probably used as sleeping-chambers by the male servants of the family. In the centre of this court there is a sunk basin or reservoir for receiving the rain, called the compluvium, rendering it likely that this was roofed over, with a well-hole to admit light and air, and allow the rain to drop from the roof into the reservoir. Connected with this outer court was the kitchen and its accessories. If the site allowed the second court to be placed beyond the first in the same direction from the entrance, the communication was by a wide opening not unlike folding doors between rooms in modern houses, generally with a space intervening, which was variously occupied; if the site did not allow of that arrangement, a mere passage led from one to the other. The second or inner vestibule, atrium, or court, is generally much larger than the first, is for the most part parallelogramic, but variously proportioned. It forms a tetrastoön, being open in the middle and arranged with a peristyle of columns, colonnading a covered walk all round. On this the best and most finished apartments open; but they are of such various sizes, and are so variously arranged, that it is not easy to determine more than that they included the refectory, the library, and sleeping-rooms. Some of them, indeed, are such as must have been useless except for the last purpose: these, perhaps, were the apartments of the female branches of a family, at least in most cases. Some houses, however, have a nest of small cells in an inner corner or secluded recess, which may have been the gynæceum; but that is far from being common. Exhedræ or recesses, open in front to the atrium, are common, and are often painted with more care and elegance than any other part of the house; but generally the walls are everywhere painted—in the more common places flat, with a slight degree of ornament perhaps, and in the best rooms with arabesques and pictures in compartments. The architectural decorations are mostly painted: the ornaments are not unfrequently elegant, but the architecture itself of the mansions is bad in almost every sense. The rooms being windowless, would, when covered, be necessarily dark; the doors are arranged without any regard to uniformity, either in size

Fig. 8.

or situation. The street-fronts of those houses which, not being in a good business situation, were not occupied with shops, were not merely unadorned, but were actually deformed by loop-holes to light some passage or inner closet which had no door on one of the courts. The columns of the second courts are generally in the worst style possible: those which have foliated capitals, and may be considered compositions of the Corinthian order, are the best; but the imitations of Doric and Ionic are both mean and ugly. From the duty they had to perform, and the wideness of their intercolumniations, together with the fact that none of them remain, it is probable that the entablatures were of wood, and were consequently burnt at the time of the destruction of the city, and broken up by the inhabitants, almost all of whom certainly escaped, and who, it is very evident, returned, when the fiery shower and the conflagration had ceased, to remove whatever they could find of their property undestroyed; for it must be remembered that the roofs and ceilings all over the city are entirely gone, and the uncovered and broken walls remain, from eight to ten feet only in height. Every thing, indeed, clearly demonstrates that great exertions were used to recover whatever was valuable; and it is very probable, moreover, that the place was constantly resorted to by treasure-seekers for perhaps centuries after the calamity occurred. It may also be remarked that the loftier edifices, which would have been unburied by the ashes, had been thrown down by a terrible earthquake about sixteen years before the volcanic shower fell, and therefore were the more easily covered. Other showers must have fallen since that which destroyed the city, to produce the complete filling up of every part and the general level throughout; as the one must have been prevented by those roofs and ceilings which were fire-proof in the first instance, and the other would be the result of the same, if it were not deranged by the subsequent excavations. It is indeed the fact, that the superstrata of ashes are evident and unbroken, while the substratum is mingled with ruins. Hence we are still uninformed as to the structure and disposition of the roofs and ceilings of the houses of the ancients. The doors, too, of whatever materials they were composed, are entirely gone: there remain, however, here and there, indications of wooden door-posts—in some cases, indeed, charred fragments of them—but they are to outer or street-doors, leaving it probable, as we have before suggested, that a matting of some kind, suspended from the lintel, formed the usual doors to rooms,—or perhaps they were closed by curtains only. In these particulars, unfortunately, Herculaneum affords but little assistance, as the mode of its destruction was similar to that of Pompeii, and it, too, was doubtlessly exposed in nearly the same manner; its subterranean situation, moreover, at present, renders it difficult to examine; but, upon the whole, Herculaneum is more likely to furnish information on these particulars than its sister in misfortune. Although it has been ascertained that the Romans understood the manufacture of glass, or at least that they possessed some utensils of that material, it must not be supposed that they were accustomed to apply it to exclude the weather and transmit light; for in no case has a glass window of any kind been discovered in any ancient structure; and, without contemplating the houses of Pompeii, it is impossible to appreciate the advantages we derive in our habitations from the application of that beautiful production of the useful arts, and how much superior it alone renders them to those of the ancients. The floors of the houses of Pompeii and Herculaneum are all of mosaic work, coarser and simpler in the less esteemed parts, and finer and more ornate in the more finished apartments: the ornaments are borders, dots, frets, labyrinths, flowers, and sometimes figures. In this, too, the superior advantages the moderns enjoy are evident. The ancients did not understand how to construct wooden floors, at least the application of timber to that use was not made by them; for, though it were admitted, which, however, it cannot be with justice, that, in the warmer climate of the south of Italy, paved floors would be more grateful, that would not be the case in this country; and we find the remains of Roman houses, baths, &c. in England, with floors of mosaic, as in Naples and Sicily. All the indications which are found in Pompeii of an upper story consist in a few rude and narrow staircases, which, it is very probable, were to afford access to the terraces or flat roofs, for they are not common, and no portion of an upper story remains in any part, though it is most likely that the lower or ground-floor rooms were arched over. In one part of the city the houses on one side of a street are on a declivity: there a commodious flight of stairs is found to lead from the atrium in front, to another atrium and rooms below, not under the houses, but behind them; for neither do we find an under-ground or cellar story in the Pompeian houses. On the shores of the Bay of Baiæ, and of the Gulf of Gaeta, at Cicero's Formian Villa, however, there are crypts or arched chambers under the level of the mansions; for the sites require substructions; but it may be questioned whether even these were used as parts of the house, and as we use cellars; for they present no indications of stairs, and have no regular means of intercommu-

Roman Structures.

Roman Structures.

nication. Neither had the houses of the Romans chimneys of any kind; their only mode of warming their apartments was by means of braziers, many specimens of which have been taken out of both Herculaneum and Pompeii; and their cooking fires were on fixed gratings over a sort of stove, but without flues; so that most probably charcoal alone was burnt for domestic purposes. In this respect the modern Italians are not far beyond their predecessors; and the mode used by them of applying fire in warming and cooking appears very similar to that used by the Romans. Indeed many of the peculiarities we have noticed in the Pompeian houses are still found in various parts of Italy and Sicily; the cortili, courts, or cloisters of palaces, mansions, monasteries, and inns, are representatives of the cavædia, vestibula, atria or courts, of Pompeian or Roman mansions. It is common, too, in the former, for bed-rooms to open on open galleries, as on the colonnaded courts of the latter. There are instances also in the countries referred to, of rooms which have no aperture but the doorway. Shops, we have said, are frequently mere cells, having an opening towards the street, part of which is a door, and the other part, with a low dado, a window. It was only in the forums and public places, then, that architectural beauty and magnificence were displayed in a Roman city. Street architecture was unknown, and the decoration of houses was the work of the plasterer and painter rather than of the architect.

If such as we have described were the imperfections and inferiority of the domestic architecture of the Romans, who knew that of the Greeks and Egyptians, and had, moreover, knowledge of the use of the arch, and were, we have reason to believe, better carpenters than either, besides possessing greater wealth, and a greater taste for luxury than they, with a less mild and serene climate than Greece and Egypt,—what must the domestic edifices of these nations have been! A person accustomed to the comforts and conveniences of houses in this country finds much to complain of in a modern Italian mansion, but not so much as an Italian would in the house of an ancient Roman; and from analogy we may believe that a Roman of the empire would have had reason to complain of a Grecian domicile, even of the Periclean age; and a Greek, again, might have been abridged of the comforts of his house in the palace of an Egyptian.

Superior as the habitations of civilized men in modern times may be to those of the ancients, a degree of classic beauty and elegance pervaded the decorations and furniture, and even the domestic utensils, in the houses of Pompeii and Herculaneum, which we do not equal, though we imitate them; and from the Hellenic taste which reigns in their forms and enrichments, their origin may probably be attributed to Greek artists; so that, it may be supposed, in these particulars the Greeks even excelled the Romans. It is indeed not a little singular, that though the architecture of these cities is completely Roman, the painted ornaments and ornamental sculpture generally are in style and manner perfectly Greek. There are certainly modifications found of Greek Doric columns in Pompeii; but they bear so slight a degree of relationship to their original, that its existence may almost be denied,—they have the form without the feeling.

Sepulchral monuments.

As works of architecture, the sepulchral monuments of the Romans were of more importance than their domestic structures. There is more architectural display in the street of the tombs at Pompeii, than in any street of the city itself; and the mausoleum of Adrian on the right bank of the Tiber at Rome was a much more important object in its perfect state than his villa near Tivoli could ever have been. It was perhaps the most splendid structure of the kind ever executed; excelling the Memphian pyramids as much in architectural pretence as they surpass it in magnitude. There was, too, a degree of harmony and simplicity in its composition, which can only be accounted for by supposing that the imperial builder, who was himself an adept in architecture, had acquired better taste than the architects of Rome generally possessed, by the contemplation of the monuments of Greece and Egypt. It consisted of a deep quadrangular basement, each of whose sides was about 250 feet in length. This was surmounted by a lofty circular mass, on which was a graduated stylobate, supporting a noble peristyle of Corinthian columns, with their entablature; forming, with its circular cone, a species of peristylar temple, something like that below the cupola of St Paul's Cathedral in London. Above this there was, most probably, a species of dome, whose acroterium is said to have been a metal pine-cone, which was the receptacle of the ashes of the emperor. The mausoleum of Augustus was, we may believe, from the descriptions which exist of it when in a more perfect state than it is at present, inferior in size, in splendour, and in good taste, to that of Adrian; but it was nevertheless a magnificent monument. Its form was conical; it diminished in stories and terraces, probably columned round, and terminated at the apex in a bronze figure of its founder. The sepulchral monuments of Cecilia Metella, of the Plautian family, and others, are evidences of the same fact. The sarcophagus from the first-mentioned of these is simple and elegant in the extreme; and indeed it exhibits a greater degree of simple beauty than almost anything of the same kind that remains to us of the Romans.

Roman Corinthian

Of the Roman Corinthian.

Like the Greek orders, the Roman Corinthian may be said to consist of three parts, stylobate, column, and entablature; but, unlike them, the stylobate is much loftier, and is not graduated, except for the purposes of access before a portico. Its usual height is not exactly determinable, in consequence of the ruined state of most of the best examples; but it may be taken at from two and a half to three diameters. In the triumphal arches the height of the stylobate sometimes amounts to four, and even to five diameters. It is variously arranged, moreover, having, in the shallower examples, simply a congeries of mouldings to form its base, with perhaps a narrow square member under it, a plain dado, and a covering cornice or coping, on the back of which the columns rest. In the loftier examples a single, and sometimes a double plinth, comes under the base mouldings; and a blocking course superimposes the coping, to receive the bases of the columns. This last is only necessary when the height of the stylobate is such as to take the columnar base above the human eye, when the coping cornice would intercept it if a blocking course did not intervene. Pl. LX. Fig. 6, 8, 9, & 10.

The column consists of base, shaft, and capital, and varies in height from nine and a half to ten diameters. The base has, ordinarily, in addition to the diminishing congeries of mouldings which follows the circular form of the shafts, a square member or plinth, whose edges are vertical: with this the whole height of the base is about half a diameter. The rest of this part of the column is variously composed, but it generally consists of two plain tori and a scotia, with fillets intervening, as in the Greek examples of this order, but differently proportioned and projected, as the examples indicate. Sometimes the scotia is divided into two parts, by two beads with fillets, as in the Jupiter Stator example, in which also a bead is placed between the upper torus and the fillet of the apophyge. The spread of the base varies from a diameter and one third to a dia- Pl. LVIII. Ex. 1.

Roman Corinthian.

meter and four ninths. In the best Roman examples, as well as in the Greek, the shaft diminishes with entasis: the average diminution is one eighth of a diameter. The shaft was always fluted when the material of which it was composed did not oppose itself; for the Romans often used granites, and sometimes an onion-like marble called therefore *cipollino*, for the shafts of columns; the former of which could not be easily wrought and polished in flutes, and the latter would scale away if it were cut into narrow fillets. Like the Greek Corinthian and Ionic orders, the Roman Corinthian has twenty-four fillets and flutes. The flutes are generally semicircles, and they terminate at both ends, for the most part, with that contour. Dividing the space for a fillet and a flute into five parts, four are given to the latter, and one to the former. The hypotrachelium is a plain torus, about half the size of the upper torus of the base, or half the width of a flute, as these nearly correspond: it rests on a fillet above the cavetto at the head of the shaft.

The ordinary height of the capital is a diameter and one-eighth; but there is a very fine example in which it hardly exceeds a diameter, and another in which it is not quite so much. It is composed of two rows or bands of acanthus leaves, each row consisting of eight leaves ranged side by side, but not in contact; of helices and tendrils trussed with foliage; and an abacus, whose faces are moulded and variously enriched. The lower row of acanthus leaves is two-sevenths the whole height of the capital; the upper row is two-thirds the height of the lower above it, and its leaves rest on the hypotrachelium below, in the spaces left between the others. They are placed regularly, too, under the helices and tendrils above, which support the angles, and are under the middle of each side of the abacus. The construction and arrangement of the next compartment above must be gathered from the examples; for a competent idea cannot be conveyed in words. The abacus is one-seventh of the height of the capital; in plan it is a square whose angles are cut off, and whose sides are concaved in segments of a circle, under an angle at the centre of from 55° to 60°. Its vertical face is generally a flat cavetto, with a fillet and carved ovalo corbelling over at an angle of about 125°. The cavetto is sometimes enriched with trailing foliage, and a rosette or flower of some kind overhangs the tendrils from the middle of each side of the abacus.

Every example of this order differs so much in the form, proportion, and distribution of the various parts, of its capital particularly, that it cannot be described in general terms, like the Greek Doric and Ionic: the example
Ex. 1. we have referred to in this definition is that of the Jupiter Stator, the most elegant, perhaps, of all the Roman specimens.

The entablature varies in different examples from one diameter and seven eighths to more than two diameters and a half in height. Perhaps the best proportioned are
Ex. 4. those of the portico of the Pantheon, and of the temple
Ex. 3. of Antoninus and Faustina; the former being rather more than two diameters and a quarter, and the latter rather less than that ratio. The entablature of the temple of Jupiter Stator is more than two diameters and a half in height, of which the cornice alone occupies one sixth more than a full diameter, leaving to the frieze and architrave somewhat less than one diameter and a half between them. In this latter particular it nearly agrees with the other two quoted examples, so that the great difference in the general height is in the cornice almost alone, the cornices of the others being about a sixth less, instead of as much more, than a diameter in height. The Roman Corinthian entablature may be taken, then, at two diameters and a quarter in height. Rather more than three fifths of this is nearly equally divided between the architrave and frieze, the advantage, if any, being given to the former; the cornice, of course, takes the remaining two fifths, or thereabouts. The architrave is divided into three unequal fascias and a small congeries of mouldings, separating it from the frieze. The first fascia is one fifth the whole height; one third of what remains is given to the second, and the remainder is divided between the third fascia and the band of mouldings,—two thirds to the former, and one to the latter. A bead, sometimes plain and sometimes carved, taken from the second fascia, which is itself enriched in the Jupiter Stator example, marks its projection over the first; and a small cyma-reversa, carved or plain as the bead may be, taken from the third fascia, marks its projection over the second. The band consists of a bead, a cyma-reversa, carved or plain according to the general character of the ordinance, and a fillet. In non-accordance with the practice of the Greeks, the face of the lowest or first fascia of the architrave, in the Roman Corinthian, impends the face of the column at the top of the shaft, or at its smallest diameter; and every face inclines inwards from its lowest face up. The whole projection of the architrave, that of the covering fillet of the band, is nearly equal to the height of the first fascia. The frieze impends the lowest angle of the architrave. Its face is either perpendicular, or it slightly inclines inwards, like the fascias of that part of the entablature: in some cases it is quite plain, and in others is enriched with a foliated composition, or with sculptures in low or half relief. The cornice consists of a deep bed-mould, variously proportioned to the corona; but it may be taken generally, when it has modillions, at three fifths, and when it has none, at one half the whole height. It is composed of a bead, an ovalo or cyma-reversa and fillet, a plain vertical member, sometimes dentilled, another bead, and a cyma-reversa and fillet or ovalo, as the lower may *not* be: this is surmounted, when modillions are used, by another plain member, with a small carved cyma-reversa above it. On this the modillions are placed, and the cyma breaks round them. They are about as wide as the member from which they project, and are about two thicknesses apart. In form they are horizontal trusses or consoles, with a wavy profile, finishing at one end in a large, and at the other in a small, volute; and under each there is generally placed a raffled or acanthus leaf. In proportioning the parts of this bed-mould in itself, one third of its height may be given to the modillion member, and the other two thirds divided nearly equally, but increasing upwards into three parts, one for the lowest mouldings, one for the plain or dentil member, and the third and rather largest portion for the mouldings under the modillion member. The mouldings of this part of the cornice are carved or left plain, according to the character of the ordinance; and its greatest projection, except the modillions themselves, that of the modillion member, is about equal to half its height. The upper part of the cornice,—the corona, with its crown mouldings,—consists of the vertical member called the corona, which is two fifths the whole height;—this, in the examples of the temples of Jupiter Stator and Antoninus and Faustina, is enriched with vertical flutes;—a narrow fillet, an ovalo, and a wider fillet, occupy one third of the rest, the other two thirds being given to cyma-recta, with a covering fillet which crowns the whole. Its extreme projection is nearly equal to the whole height of the cornice.

The ordinance of the temple of Vesta, or of the sibyl Ex. 2.
at Tivoli, whose entablature is the very low one mentioned, is not generally in accordance with the scale we have given, and it must be referred to for its own peculiar proportions.

Roman Corinthian.

Pediments with the Roman Corinthian order are found to be steeper than they were made by the Greeks, varying in inclination from eighteen to twenty-five degrees; but they are formed by the cornice of the entablature in the same manner. Antefixæ do not appear to have been used on flank cornices as in Greek ordinances, in which the cymatium is confined to pediments; but in Roman works it is continued over the horizontal or flank cornice, as we have described; and frequently it is enriched with lions' heads, which were at the first introduced as water-spouts. The planceer or soffit of the corona is, in the Jupiter Stator example, coffered between the modillions, and in every coffer there is a flower. The soffit of the entablature in this order is generally panelled and enriched with foliated or other ornament. The intercolumniation is not the same in any two examples. In the temple of Vesta in Rome it hardly exceeds a diameter and a quarter; in the Jupiter Stator example it is a fraction less than one diameter and a half, in that of Antoninus and Faustina, nearly a diameter and three quarters; in the portico at Assisi, rather more than that ratio; in the portico of the Pantheon, almost two diameters; and in the Tivoli example, a fraction more than that proportion.

The antæ of the Roman Corinthian order are generally parallel; but pilasters are mostly diminished and fluted as the columns. Of two of the existing examples of antæ, in one—that of the temple of Mars Ultor—they are plain, to fluted columns; and in the other—that of the Pantheon portico—they are fluted, to plain columns. The capitals and bases are transcripts of those of the columns, fitted to the square forms.

Ceilings of porticoes are formed, as in the Greek style, by the frieze returning in beams from the internal architrave to the wall or front of the structure, supporting coffers more or less enriched with foliage or flowers. This, however, could only have been effected when the projection was not more than one, or at the most two intercolumniations, if stone was used; and it is only in such that examples exist. Porticoes ordinarily must have had arched ceilings, as that of the Pantheon has, or the beams must have been of wood; in which latter case probably the compartments of the ceiling would be larger. How, in the former, it was arranged we cannot tell, as the arches only remain; and they may not be of the date of the rest of the portico.

Pl. LIX. Ex. 2. The ancient examples of what is called the Composite order do not differ so much from the ordinary examples of the Corinthian as the latter do among themselves, except in the peculiar conformation of the capital of the column. In other respects, indeed, its arrangement and general proportions are exactly those of the Corinthian. The Composite was used, we have said, in triumphal arches, and, in the best ages of Roman architecture, in them alone. The difference in the capital consists in the enlargement of the volutes to nearly one fourth the whole height of the capital, and in connecting their stems horizontally under the abacus, giving the appearance of a distorted Ionic capital. The central tendrils of the Corinthian are omitted, and the drum of the capital is girded under the stem of the volutes by an ovalo and bead, as in the Ionic. Acanthus leaves, in two rows, fill up the whole height from the hypotrachelium to the bottom of the volutes, and are consequently higher than in the Corinthian capital: this difference is given to the upper row. Besides this Composite, however, the Romans made many others, the arrangements and proportions of the ordinances being generally those of the Corinthian order, and the capitals corresponding also in general form, though in themselves differently composed. In these, animals of different species, the human figure, armour, a variety of foliage, and other peculiarities, are found. Shafts of columns also are sometimes corded or cabled instead of being fluted: those of the internal ordinance of the Pantheon are cabled to one third their height, and the flutes of the antæ of that ordinance are flat, eccentric curves. There are fragments of others existing, in which the fillets between the flutes are beaded; some in which they are wider than usual, and grooved; others, again, whose whole surface is wrought with foliage in various ways; and it would be no less absurd to arrange all these in different orders, than it is to make a distorted and hybrid capital the ground-work of an order.

Roman Ionic.

Of the Roman Ionic.

The only existing example of this in Rome, in which the columns are insulated, is in the Temple of Manly Fortune, except that of the Temple of Concord, which is too barbarous to deserve consideration. Its stylobate, like that of the Roman Corinthian, is lofty and not graduated, having a moulded base and cornice or surbase. The column is nearly nine diameters in height; its base is half a diameter in height, and consists of a plinth, two tori, a scotia, and two fillets; the shaft has twenty fillets and flutes, and diminishes one tenth of a diameter; the capital is two fifths of a diameter in height; the volutes, however, dip a little lower, being themselves about that depth without the abacus; the corbelling for the volutes is formed by a bead and large ovalo, half the height of the capital; the latter of these is carved: a straight band connects the generating lines of the volutes, whose ends are bolstered and enriched with foliage; and a square abacus, moulded on the edges, covers the whole. The entablature is rather less than two diameters high; three tenths of this are given to the architrave, the same to the frieze, and the cornice occupies the remaining two fifths. The architrave is unequally divided into three fascias, and a band consisting of a cyma-reversa and fillet; the lowest angle impends the upper face of the shaft of the column. The frieze is in the same vertical line, and is covered with a fillet which receives the cornice; it is also enriched with a composition of figures and foliage. The cornice consists of a bed-mould, two fifths of its height, and a corona with crown mouldings. The bed-mould is divided nearly equally between a cyma-reversa and fillet, a square dentilled member and fillet, and another fillet and ovalo. The corona is two fifths the height of the rest of the cornice; another fifth is occupied by two fillets and a cyma-reversa, and the rest is given to a cyma-recta and crowning fillet. The whole projection is nearly equal to the height of the cornice. The cymatium is enriched with acanthus leaves and lions' heads, and the mouldings of the bed-mould and architrave band are carved. The soffit of the corona is hollowed out in a wide groove, whose internal angles are rounded off in a cavetto, but without ornament of any kind, forming indeed a mere throating. Like the angular capitals of the Greek Ionic, the external volute of this is turned out and repeated on the flank: either that or the abuse of it in the Composite capital gave rise to distortions of this order, in which all the volutes of the capital are angular, and consequently all its four faces are alike. In other respects, however, it does not differ generally from the ordinary Roman examples of Ionic. The Temple of Manly Fortune is pseudo-peripteral, and consequently has neither antæ nor pilasters, nor do ancient examples exist of either.

Pl. LX. Fig. 12.

Pl. LIX Ex. 2.

Pl. LX. Fig. 12.

Of the Roman Doric.

This is even a ruder imitation of the Grecian original than the mean and tasteless deterioration of the voluted Ionic is of the graceful Athenian examples. The specimen of it which is considered preferable to the others is

Pl. LIX. Ex. 4.

Roman Doric.

that of the theatre of Marcellus in Rome. The column is nearly eight diameters in height: it consists of shaft and capital only. The shaft is quite plain, except fillets above and below, with escape and cavetto; and it diminishes one fifth of its diameter. The capital is four sevenths of a diameter high, and is composed of a torus which forms the hypotrachelium, and, with the necking, occupies one third of the whole height. Three deep fillets, with a semitorus or quarter-round moulding, are intended to represent the ovalo and its annulets of the Greek capital. They occupy three sevenths of the rest; the other four sevenths are given to the abacus, three fifths of whose depth is plain and vertical; and the other two is divided between a cyma-reversa and a fillet.

The corona and crown mouldings of the cornice being destroyed, the whole height of the entablature cannot be correctly ascertained; but from analogy it may be taken, with the bed-mould, part of which exists, at about two thirds of a diameter, making, with the architrave and frieze, an entablature nearly two diameters high. Of this the architrave is rather more than one fourth, indeed exactly half a diameter. Three tenths of its depth are unequally occupied by the tænia, regula, and guttæ, the first being rather the widest, projecting more than its own depth, and the second the narrowest. The guttæ are six in number, and are truncated semicones in form. The rest of the surface of the architrave is plain and vertical, impending a point rather within the superior diameter of the column. The frieze is two fifths the whole height of the entablature. A fascia, one eighth of its own height, bands it above the triglyphs, and projects about one third of its depth; the rest of its surface is plain vertically, but horizontally it is divided into triglyphs, which are half a diameter in width, and are placed over the centres of the columns. These are channelled with two full and two hemiglyphs, whose heads are cut square on the outer edge, but inclined downwards at the angle of the glyphs. The space between the triglyphs is equal to the height of the frieze without its plat-band or fascia, making in effect perfectly square metopes. All that can be traced of the cornice is a small cyma-reversa, immediately over the frieze, and a square member with dentils on it. In the example the cornice is completed from that of the Doric of the Colosseum.

The temple at Cora presents a singular specimen of the Doric order, evidently the result of an examination of some Greek examples, but moulded to the Roman proportions and to Roman taste. The columns are enormously tall, but the shafts are partly fluted and partly chamfered for fluting, like the Greek. The capital is ridiculously shallow, but the abacus is plain, and the echinus of a somewhat Hellenic form. The entablature is very little more than a diameter and one third in height, and the architrave of it is shallower even than the capital; but the frieze and cornice are tolerably well proportioned, though the triglyphs in the former are meagre, narrow slips, and the latter is covered by a deep widely projecting cavetto, that would be injurious to even a better composition. Instead of regular mutules with guttæ, the whole of the planceer of the cornice is studded with the latter; but, like the Greek, the triglyph over the angular column extends to the angle of the architrave, which does not appear to have been the practice of the Romans; yet the reason for so doing does not appear to have been understood, for the external intercolumniations are the same as the others.

As far as we have the means of judging, the Romans made the antæ of their Doric similar to the columns, only that they were of course square instead of round; though indeed an attached column appears to have been generally preferred.

Roman Mouldings.

It may, however, be here again intimated, that these two orders, the Ionic and Doric of the Roman school, ought hardly to be considered as belonging to the architecture of the Romans. They are merely coarse and vulgar adaptations of the Greek originals, of which we now possess records of the finest examples. If it were not, therefore, that custom required it, we should have omitted all mention of them, or at least have left them to the Italo-Vitruvian school, to which they properly belong. Yet their meanness and tastelessness, when compared with the Grecian models, will more strikingly show the superiority of the latter, and show, moreover, how the architects of the Italian school must have been blinded by their system, when they fancied such wretched exemplars as those of which we have been speaking to be beautiful.

Of Roman Mouldings and Ornament.

Pl. LVII.

The mouldings used in Roman architectural works are the same as the Grecian in general form, but they vary materially from them in contour. The Roman cyma-recta is projected much more than the Greek, with a deeper flexure; and the two parts or ends seldom correspond, the one being generally larger than the other. On the contrary, the Roman cyma-reversa does not project so much, or at so large an angle with its base, as the Grecian, nor is it so deeply flected as the Greeks made it. The upper or convex part of this moulding is almost always larger than the lower or concave; and it is frequently allowed to finish below in a sharp arris projecting from whatever is below it, and above it abuts upon the horizontal soffit of its covering fillet in a similarly harsh manner. The ovalo of Greek architecture is represented in the Roman style by a moulding whose outline is nearly the convex quadrant of a circle, or a quarter round, and sometimes it is nearly that of the quadrant of an ellipsis. The Roman torus is either a semicircle or a semi-ellipsis; and the bead is a torus, except in its application, and in being smaller, and generally projected rather more than half the figure whose form it bears. The cavetto, in Roman architecture, is nearly a regular curve, being sometimes the concave quadrant of a circle, or indeed the reverse of an ovalo, and sometimes a smaller segment. A Roman scotia is more deeply cut, and is consequently less delicate than the same member in a Greek congeries: its form frequently approaches that of a concave semiellipsis.

This correspondence in general form, and disagreement in spirit, of Greek and Roman mouldings, appear to have arisen entirely from the ignorance or inattention of the Romans to the governing principle of Greek combinations; as we have seen that in these the individual mouldings are not independent, as the Romans made them, but that they take their contour and direction from each other, under a certain pervading outline.

The enrichments of Roman mouldings are for the most part similar to those of the Greek, but less delicate and graceful both in design and drawing. Those of the cyma and ovalo are particularly referred to, but the Romans used others besides. Raffled leaves form a favourite enrichment in the architecture of the Romans: indeed these are hardly less frequent in their works than the honeysuckle is in those of the Greeks. Mouldings were enriched with them; and a raffled leaf masks the angles of carved cymas and ovalos in the former, as a honeysuckle does in the latter. Nevertheless, the honeysuckle and lotus are both found in Roman enrichments, particularly the latter, and perhaps even more than in Greek. It is not uncommon to find examples of Roman architecture completely overdone with ornament,—every moulding carved, and every straight surface, whether vertical or

Italian Architecture.

horizontal, sculptured with foliage, or with historical or characteristic subjects in relief. This fault is most obvious in those works which exhibit similar bad taste in the general composition. The triumphal arch of Septimius Severus, the little arch of the goldsmiths, and the half-buried ruin called the temple of Pallas, in the forum of Nerva at Rome, are egregious specimens. The entablature of the arch of Titus, too, is overloaded with ornament.

Frieze enrichments, consisting of foliage composed with animals, and a variety of other things, are very common in Roman architecture. Many specimens indeed are not found in existing structures, but there are numerous fragments of entablatures of destroyed edifices which exhibit them in great variety. Their general character is exuberance, and a tendency to frittering, from the variety and incoherence of form in their composition; but their effect can only fairly be judged of when seen in appropriate situations. One existing example of an enriched frieze of the kind referred to, that of the temple of Antoninus and Faustina, speaks strongly in its favour, for nothing can surpass its efficiency and simple beauty; but it must, moreover, be confessed that, when examined in detail, the enrichment is less exuberant, and is composed of fewer parts, than most others of the species to which that example belongs. Architectural ornament, however, is not confined to purely architectural works. We find many beautiful specimens of it on the vases and candelabra which decorated the baths and mansions of the ancient Romans, and whose elegance of form rivals even the beauty and delicacy of their enrichments. Whether these should be referred to the Romans or not, is doubtful; for it has been already intimated, from the style of many of them, both in outline and ornament, which appertain more to the Greek, that they are the productions of Grecian artists; but indeed they belong exactly to neither, for they frequently possess the beauties, and sometimes exhibit the defects, of both. There are existing works, clearly of Roman origin, far inferior in every respect to the objects last mentioned. These are for the most part cenotaphial monuments, sarcophagi, and altars, whose composition, details, and enrichments, are gross and inelegant when compared with the objects alluded to. The difference may arise merely from the inferiority of the artists of the one to those of the other, and not from the difference of their schools; but the prevalence of Greek taste in the superior productions is not the less striking because it was acquired by education, while it is wanting in the inferior, whose authors had not been imbued with the spirit and fine feeling of the Greek style.

Of Italian Architecture.

Gothic architecture,—that is, the style which preceded the Pointed,—being for the most part a mere deterioration of Roman, and possessing no peculiar character which can recommend it as a subject for study and imitation that may not be deduced from the Roman style, and Pointed architecture being a genus *per se*, we have thought it better to allow the Italian, or revived Roman style, to usurp its chronological place; as the latter more naturally follows what it pretends to be derived from, than it would follow the Pointed, or than the Pointed would the Roman.

We have already stated that Italian architecture, though professedly a revival of the classical styles of Greece and Rome, was formed without reference to the existing specimens of either, but on the dogmas of an obscure Roman author, and the glosses of the "revivers" on his text. Vitruvius described four classes or orders of columnar composition; and, on the principles which governed him in subjecting to fixed laws all the varieties with which he appears to have been acquainted, they formed a fifth, of a medley of two of his, thus completing the Italian orders of architecture. The school which was founded on the Vitruvian theories has systematized every thing, and laid down laws for collocating and proportioning all the matter it furnishes for architectural composition and decoration. It teaches that columns are modelled from the human figure; that the Tuscan column is like a sturdy labourer—a rustic; the Doric is somewhat trimmer, though equally masculine—a gentleman, perhaps; the Ionic is a sedate matron; the Corinthian a lascivious courtesan; and the Composite an amalgam of the last two! In a composition which admits any two or more of them, the rustic must take the lowest place; on his head stands the stately Doric, who in his turn bears the comely matron, on whose head is placed the wanton, and the wanton again is made to support the lady of doubtful character! But as we in this place are neither apologists for nor impugners of any particular doctrines, we proceed at once to point out the general features of the Italian style; premising only, that, according to the practice of the school, every thing is confined to an exclusive use and appropriation; such columns may be fluted, and such must not; such a moulding may be used here, but not there; and so on. The proportions and arrangements of an order, of any part of one, or of any thing that may come within an architectural composition, are fixed and unchangeable, whatever may be the purpose or situation for which it is required; whether, for instance, an order be attached or insulated, the column must have exactly the same number of modules and minutes in height. It is true that the masters of the school are not agreed among themselves as to those things in which they are not bound by Vitruvius; but every one not the less contends for the principle, each, of course, prescribing his own doctrine as orthodox on the unsettled points.

Mouldings are considered as constituent parts of an order, and are limited to eight in number, strangely enough including the fillet. They are the cyma-recta, cyma-reversa, commonly called the ogive or ogee, the ovalo, the torus, the astragal or bead, the cavetto, the scotia, and the fillet. They are gathered from the Roman remains, but reduced to regular lines or curves, which may be drawn with a rule or struck with a pair of compasses. Arranged according to certain proportions, with flat surfaces, modillions, and dentils, a profile is formed; no two conjoined mouldings may be enriched, but their ornaments, as well as the modillions and dentils, must be disposed so as to fall regularly under one another, and, when columns occur, above the middle of them.

An order is said to be composed of two principal parts, the column and the entablature; these are divided into base, shaft, and capital, in the one, and architrave, frieze, and cornice in the other, and are variously subdivided in the different orders. The Tuscan column must be made seven diameters in height, the Doric eight, the Ionic nine, and the Corinthian and Composite ten. The height of the entablature, according to some authorities, should be one fourth the height of the column, and, according to others, two of its diameters. The parts of the entablature of all but the Doric may be divided into ten equal parts, four of which are given to the cornice, three to the frieze, and three to the architrave; and in the Doric, the entablature being divided into eight parts, three must be given to the cornice, three to the frieze, and the remaining two to the architrave. For the minor divisions a diameter of the column is made into a scale of sixty minutes, by which they are arranged; but this is obviously irrelevant if the whole height of the entablature is determined by Pl. LXII.

Italian Architecture.

the height of the column, and not by its diameter; in this case, therefore, they must be proportioned from the general divisions already ascertained. Columns must be diminished, according to Vitruvius, more or less as their altitude is less or greater; those of fifteen feet high, or thereabout, being made one sixth less at their superior than at their inferior diameter, and that proportion is lessened gradually, so that columns fifty feet high shall be diminished one eighth only. On this subject, however, many of his disciples controvert the authority of their master; and some of them have fixed the diminution at one sixth of a diameter for columns of all sizes in all the orders. The entasis of columns is disputed also, some authorities making it consist in preserving the cylinder perfect one quarter or one third the height of the shaft from below, diminishing from thence in a right line to the top; while others, following Vitruvius, make the column increase in bulk in a curved line from the base to three sevenths of its height, and then diminish in the same manner for the remaining four sevenths, thus making the greatest diameter near the middle.

It being difficult to determine among the masters of the Italo-Vitruvian school whose designs of the various orders are to be preferred, we have selected those of Palladio, certainly not for any superior merit they possess, but because he is more generally esteemed than any other, and because he the most strictly adhered, as far as he could understand them, to the precepts of Vitruvius. It should be remarked, however, that although Palladio has fluted all but the shaft of the Tuscan column, he very seldom fluted columns in his own practice; and indeed it may be called the custom of the Italian school not to flute, how much soever their doctrine may be to the contrary; for fluted columns in Italian architecture are exceptions to the general practice. Swelled or pillowed friezes are not peculiar to Palladio; they are more or less common to the works of most of the masters of the same school. Prostyles being almost unknown in Italian architecture, antæ are not often required; but when they are, the meanest succedaneum imaginable is recurred to. Of this, Palladio's Villa Capra near Vicenza, and Lord Burlington's Palladian Villa at Chiswick, afford striking examples. Pilasters, however, are very common, so common, indeed, that they may be called pro-columns, as they are often used as an apology for applying an entablature. They are described as differing from columns in their plan only, the latter being round, and the former square; for they are composed with bases and capitals, they are made to support entablatures according to the order to which they belong, and are fluted and diminished with or without entasis, just as columns of the same style would be. When they are fluted, the flutes are limited to seven in number on the face, which, it is said, makes them nearly correspond with the flutes of columns; and their projection must be one eighth of their diameter or width when the returns are not fluted; but if they are, a fillet must come against the wall. Pedestals are not considered by the Italo-Vitruvian school as belonging to the orders, but they may be employed with them all, and have bases and surbases or cornices to correspond with the order with which they may be associated. The dado of a pedestal must be a square whose side shall be equal to that of the plinth of the column or pilaster which rests on it, or a parallelogram a sixth or even a fourth of a diameter taller. The intercolumniations of columns are called pycnostyle, systyle, eustyle, diastyle, and aræostyle, and are strictly adhered to in Italian architecture when columns are insulated, and that is not very often; when they are attached, the interspaces are not limited, except when a peculiar arrangement called aræosystyle is adopted. This consists of two systyle intercolumniations, the column that should stand in the mid-distance between two others being placed within half a diameter of one of them, making in fact coupled columns or pilasters. It is applied to insulated columns as well as to those which are attached. Following Vitruvius, the Italian school makes the central intercolumniation of a portico wider than any of the others. Arched openings, in arcades or otherwise, are generally about twice their width in height; if, however, they are arranged with a columnar ordinance, having columns against the piers, they are made to partake of the order to which the columns belong, being lower in proportion to their width with the Tuscan than with the Doric, and so on; and the piers are allowed to vary in the same manner, from two fifths to one half of the opening. With columnar arrangements, moulded imposts and archivolts are used; the former being made rather more than a semidiameter of the engaged columns in height, and the latter exactly that proportion. Variously moulded key-stones are used, too, projecting so that they give an appearance of support to the superimposed entablature. Smaller columns with their entablature are sometimes made to do the duty of imposts, and sometimes single columns are similarly applied; at others, columns in couples are allowed to stand for piers to carry arches. In plain arcades the masonry is generally rusticated, without any other projection than a plain blocking course for an impost, and a blocking course or cornice crowning the ordinance. Niches and other recesses are at times introduced in the plain piers, which are in that case considerably wider than usual, or in the spandrels over wide piers. Very considerable variety is allowed in these combinations, which will be best understood by reference to the examples. Doors and windows, whether arched or square, follow nearly the same proportions, being made, in rustic stories, generally rather less than twice their width in height, and in others either exactly of that proportion, or an eighth or a tenth more. If they have columned or pilastered frontispieces, these are sometimes pedimented; and, except in rustic stories, whether with or without columns, a plain or moulded lining called an architrave is applied to the head and sides of a door or window. This architrave is made from one sixth to one eighth the width of the opening it bounds, and it rests on a blocking course or other sill, as the case may be. In the absence of columns or pilasters in the frontispiece, their place is frequently supplied by consols or trusses of various form and arrangement, backed out by a narrow pilaster, which may be considered as the return of the frieze of the entablature, and supporting the cornice. It is not uncommon for the architrave lining to project knees at the upper angles, and this is sometimes done even with consols and their pilasters. With columned frontispieces to gateways, doors, and windows, arose the custom, so frequent in Italian architecture, of rusticating columns, by making them alternately square and cylindrical, according to the heights of the courses of rustic masonry to which they are generally attached, and with which they are less offensive than in other collocations. The practice of the *Cinquecento* school of piling columns on columns, with their accessories, is warranted by the doctrine of its master; but his precepts not being practicable, recourse has been had to the inferior works of the Romans, which present examples of it. The difficulty of preserving any thing like a rational arrangement is acknowledged on all hands to be great, ir not insurmountable; for if the first or lowest order be at an intercolumniation fitting its proportions, the second or next above it, though diminished ever so little, is already deranged, for it has the same distance from column to column that the inferior order has, whilst the columns themselves are smaller in diameter, and their entablature

Pl. LXVI. Fig. 3. — Pl. LXIII. — Fig. 11 & 12. — Fig. 12. — Fig. 10. — Fig. 13. — Fig. 2 & 4. and Plate LVI. Fig. 2. — Plate LX. Fig. 1.

Italian Architecture.

consequently shallower. This derangement must of course increase with every succeeding ordinance, rendering it indeed impossible to make such a composition consistent. The most approved practice in arranging order above order appears to be, that the upper column shall take for its diameter the superior diameter of the one below it; that when the columns are detached their axes shall be in the same perpendicular line; but when attached or engaged, the plinth of the pedestal of the upper shall impend the top of the shaft of the lower column. The most rational mode, however, for diminishing, if reason can be applied to such compositions, is to carry the diminution through, the outlines of the columns of the lowest order being drawn up in the same direction, and so the columns of every story would take up their place and be diminished in regular gradation. When columns are attached, or pilasters used, in Italian architecture, the almost invariable custom is to break the entablature over every column or pilaster, or over every two when they are in couples. Because of the great length of the intercolumniation, it would appear to have been done at first; but it has frequently been done by some of the most esteemed practitioners of the school, even without that excuse, so that it may be held as approved by them. A basement is either a low stereobate or a lofty story, as it may be intended to support a single ordinance the whole height of the main body of the structure, or indeed the lowest of two or more orders; or as it may occupy the ground story of a building, and support an ordinance, or the appearance of one, above. In either case, much is necessarily left to the discretion of the architect; but in the latter the height of the order it is to support is the generally prescribed height of the basement. A basement may be rusticated or plain; if it be low, and is not arranged like a continued pedestal, it must have neither cornice nor blocking course; but if lofty, a deep, bold, blocking course is indispensable. An attic may vary in height from one quarter to one third the height of the order it surmounts; attics are arranged with a base, dado, and coping cornice, like pedestals, and generally have pilasters broken over the columns below. The rule for the form, composition, and application of pediments in Italian architecture, if it may be gathered from the practice of the school, appears to be to set good taste at defiance in them all. We find pediments of every shape, composed of cornices, busts, scrolls, festoons, and what not, and applied in every situation, and even one within another, to the number of three or four, and each of these of different form and various composition. The proportion laid down for the height of a pediment is from one fourth to one fifth the length of its base, or the cornice on which it is to rest. Balustrades are used in various situations, but their most common application is in attics or as parapets, on the summits of buildings, before windows, in otherwise close continued stereobates, to flank flights of steps, to front terraces, or flank bridges. Their shapes and proportions are even more diversified than their application: that of most frequent use is shaped like an Italian Doric column, compressed to a dwarfish stature, and consequently swollen in the shaft to an inordinate bulk in the lower part, and having its capital, to the hypotrachelium, reversed to form a base to receive its grotesque form. The base and coping cornice of a balustrade are those of an ordinary attic, or of a pedestal whose dado may be pierced into balusters. The general external proportions of an edifice, when they are not determined by single columnar ordinances, appear to be unsettled. The grand front of the Farnese Palace in Rome is in two squares, its length being twice its height; the length of each front of Vignola's celebrated pentagonal palace of Caprarola is twice and a quarter its height above the bastions. In Palladio's works we find the proportions of fronts to vary so considerably, as to make it evident that he did not consider himself bound by any rule on that point. In some cases we find the length to be once and one sixth the height, in others once and a fourth, once and a half, twice, twice and a sixth, and even thrice and a sixth; and elevations by other masters of the school are found to vary to the same extent. The proportions of rooms, again, range from one to two cubes inclusive, though it is preferred that the height should be a sixth, or even a fifth less than a side when the plan is a square; but the sesquialteral form, with the height equal to the breadth, and the length one half more, is considered the most perfect proportion for a room. There is considerable variety and beauty in the foliate and other enrichments of an architectural character in many structures in Italy, but very little ornament enters into the columnar composition of Italian architecture. Friezes, instead of being sculptured, are swollen; the shafts of columns, it has been already remarked, are very seldom fluted, and their capitals are generally poor in the extreme; mouldings are indeed sometimes carved, but not often; rustic masonry, ill-formed festoons, and gouty balustrades, for the most part supply the place of chaste and classic enrichments. This refers more particularly to the more *classic* works of the school; in many of the earlier structures of Italy, especially those of the Trecento period, and on monuments of various kinds, we find what may be called a graceful profusion of ornament, of the most tasteful and elegant kind; few carved mouldings, however, and very few well-profiled cornices, are to be met with in Italian compositions of any kind. In many of the later architectural works of that country we find again a profusion of ornament of the most tasteless and inelegant description, chiefly in the gross and vulgar style, which is distinguished as that of Louis XIV. of France.

Pl. LXVI. Fig. 1.

Pointed Architecture.

Of Pointed Architecture.

There are so many varieties of this beautiful style, and the variations are at the same time so considerable and so minute, that it is impossible to describe it generally. Every country in which it was practised had some peculiarities in its composition, and, to develope it perfectly, all of them should be pointed out. This, however, would far exceed our limits; and as the specimens of our own are not excelled, if indeed they are equalled, by those of any other country, a consideration of the style as exhibited by them will afford us a better opportunity of developing it than could be obtained by making our observations more general.

Various classifications of Pointed architecture have been made, and in almost all of them the arch is considered the index, as the column is in columnar architecture; for, like that, it is more expressive of variety than any other feature in the composition to which each belongs. These, too, form the grand distinctions between the Greek and its derivative styles, and the Pointed; but, independently of the column in the one and the arch in the other, the two species of architecture may be said each to have certain governing principles, which sufficiently distinguish and make it impossible to mould them together in one composition, and almost to apply any of the leading forms of the one to the other. They may be thus generally laid down. In Greek and Roman architecture the general running lines are horizontal, as in entablatures and single cornices. In Pointed, the general running lines are vertical. In the former, arches are not necessary to a composition; in the latter, arches are a really fundamental principle. In Greek and Roman, again, columns require an entablature; in the Pointed style no such thing as an entablature composed of parts is appli-

Pointed Architecture.

cable to the pillars, columns, or shafts. (*Vide* Rickman's *Attempt*, &c. p. 110.)

These, however, only determine the generic differences which exist; the varieties in the former styles we have found to be marked by such and such distinctive features in the columns and their accessories, which allowed them to be divided into orders. In the latter the varieties arise chronologically, and, consisting for the most part in the forms and arrangements of details, are not incoherent; nor are certain proportions either fixed or determinable, and consequently they cannot be rendered into orders.

It has been customary, in treating of Pointed architecture, to class with it the Saxon and Norman Gothic styles. This is at least unnecessary, as they have no direct relation to it, except that of immediate precedence in point of time, and that the one was the stock on which the other was grafted. The peculiarities of Pointed architecture are indeed totally independent of those of its predecessor the Gothic; nevertheless we should hardly be excused for passing over the latter in total silence.

According to the best authorities, there are very few specimens of architecture now in existence in this country which can properly be called Saxon, that is, of a date anterior to the Conquest, and not of Roman origin; and those few are of the rudest and most inferior description. Saxon, therefore, as far as the architecture of this country is concerned, is an improper term. All the ancient structures which are distinguished by the semicircular
Pl. LXVII. arch may be called Anglo or Anglo-Norman Gothic. It
Fig. 1, 2, consists principally of massive columnar piers supporting
3, 4, 5, 6. semicircular arches, similarly arched doors and windows,
7, 8, & 9. and arches on small columns in relief, against a dead wall, to ornament it. The pier when round has a rudely foliated or a rounded capital, and generally a moulded base, and is variously ornamented on the surface, being altogether a rude resemblance of the columns of Roman architecture: it is at times polygonal, and sometimes piers consist of clusters of small round shafts. Frequently in doors and windows thin columns with rude capitals and bases receive the mouldings of the arched head; and, when the opening is divided, such columns are placed like mullions, to support the inner arches. There are examples of this style which are quite plain in every particular; but it is generally enriched by deep congeries of mouldings on the arches, which, when there are no columns, run down the jams of doors. These are again frequently carved, and mostly with the zigzag or chevron ornament: grotesque masks, and rude representations of animals, foliage, and flowers, form also common enrichments in Anglo-Gothic architecture.

This style prevailed down to the reign of Henry II. of England, when the pointed arch made its appearance. A degree of impressive grandeur pervades its productions, notwithstanding their clumsiness, arising from the great simplicity of manner and massiveness of proportion by which it is distinguished. The best existing specimens in London are the vestibule of the Inner Temple church, which, moreover, exemplifies the transition; many parts of the church of St Bartholomew in Smithfield, and the chapel of the Tower of London. Exemplifications of the style are also to be found in the interiors of Norwich, Chichester, Gloucester, Canterbury, Worcester, Rochester, Winchester, Durham, Peterborough, Oxford, and Hereford Cathedrals. According to Mr Rickman, the naves of Peterborough and Rochester are the most unmixed specimens. Parts, which are easily distinguished, of the exteriors of many of the same edifices, portions of Lincoln, and the towers of Exeter Cathedrals, Bigod's Tower at Norwich, and the White Tower in the Tower of London, afford characteristic external examples of the Anglo-Gothic style. The most striking castellated remains are those of Rochester in Kent, Hedingham in Essex, Consibrough in Yorkshire, and Guildford in Surrey. Many minor edifices, principally ecclesiastical, exist in almost every county in England. Mr Rickman remarks two specimens of this style as peculiarly deserving of attention; the one in the vestibule or entrance of the chapter-house at Bristol, and the other in the staircase leading to the registry of Canterbury Cathedral; the former for its simplicity and beauty of composition, and the latter for its singularity, and as exhibiting a very fine specimen of enrichment. The roofs, or ceilings rather, of the Anglo-Gothic edifices, were mostly of wood; but there are various examples of stone-groined ceilings to be found in crypts, which appertain to this style. Spires were unknown: there are, however, turrets crowned with large pinnacles of a date anterior to the introduction of the pointed arch, as in Rochester Cathedral, and the Church of St Peter in the East at Oxford. Towers were not uncommon; they are square massive structures, rising to no great height above the roof of the buildings to which they are attached. It may be remarked in addition, that many of our ancient structures retain the circular-headed or Anglo-Gothic door, when all the rest has been removed, and replaced by work of a later date.

Architects and antiquaries have generally agreed in dividing Pointed architecture into three styles of three succeeding periods. The first commences with the establishment of the pointed arch, and the formation of the style or manner which accompanies it, in the latter part of the twelfth century, the time of Henry II. of England; the second arose in the beginning of the fourteenth century, in the latter part of the reign of Edward I., and was itself superseded before that century closed, about the time of Richard II., by the third style, which is the latest, for with it, on the introduction of the *Cinque-cento*, Pointed architecture ceased to exist. A difficulty arises in appropriately naming these three styles, for on that point there is no degree of accordance among those who are best qualified to be considered as authorities. Mr Rickman calls the first the "Early English" style, the second the "Decorated English," and the third the "Perpendicular English;" to all of which terms Mr Britton objects, and, without giving appellations, except to the first, which he calls the "Lancet Order of Pointed Architecture," suggests that the second might be named with propriety the "Triangular Arched," and the third the "Obtuse Arched." Objecting strongly to the term "Order," used by Mr Britton, we think with him that the first might be appropriately called the "Lancet Arch" style; but his other distinctions are certainly not more defensible than Mr Rickman's. In the absence, therefore, of unobjectionable distinctive terms, as the varieties arise chronologically, we will speak of them as Periods.

Of the First Period of Pointed Architecture.

Mr Rickman describes this style as being distinguished Plate
by pointed arches, and long narrow windows without LXVIII.
mullions, and a peculiar ornament, which, from its resem- Fig. 1.
blance to the teeth of a shark, he calls the toothed ornament. There is very considerable variety in the forms and proportions of its different examples, as they retain the massive character of the Anglo-Gothic, or tend to the more florid style of the next period. In the former the Pl. LXVII.

singly or triply, with light clustered columns, against the Fig. 1.

Pointed Architecture.

piers which divide them, receiving the deep congeries of mouldings which forms the archivolt. Its columned pier, too, consists of clustered shafts, generally on a round core, and always forming cylindrical masses, girded at different heights with slight rings or belts of mouldings. Their capitals consist for the most part of congeries of mouldings following the form of the shafts, though rich and flowering capitals are not uncommon. Moulded bases, too, are generally used, not dissimilar in form to what is called the attic base of Italian architecture.

Pl. LXVII. Fig. 14. Plate LXIX. Fig. 1.

The lancet arch is described from two centres about an acute-angled isosceles triangle in the line of its base, with a radius equal to twice and one third (in some cases more, and in some less) the length of that base, or of the span the arch is to embrace. This, though the ordinary, is not, however, the universal form of the arch in the first period; but the absence of mullions, and in general of tracery, may almost be considered a criterion: yet foliations or featherings are not uncommon, especially in doors, and as enrichments to flat surfaces, though every thing of the kind certainly indicates an approach to the style of the succeeding period. Ribs on the angles formed by the intersections of arches in groined ceilings, not in ramified tracery, but with bosses at their apices alone, appertain to works of the first period. These ribs sometimes spring from corbels, and sometimes from the heads of slight shafts, which may run uninterruptedly from the floor to the springing of the arched ceiling, against the walls or against the columnar piers; and a small cornice or tablet continuing round them, runs along horizontally to separate the vertical from the vaulted surface. Buttresses in general, of various forms, sometimes in diminishing stages and sometimes upright, with acutely gabled heads without crockets, but having finials—and flying buttresses in particular—belong to this style. The tablets or cornices, mouldings, ornaments, and the variety and arrangement of niches, must be gathered from examples. The parapet or battlement is straight and uninterrupted, and is either plain or ornamented with series of arches or panels with foliations. Turrets are in some cases square, in others octagonal; but the pinnacles which surmount them are almost always of the latter form, and plain or crocketed, as the work may be more or less ornate. Towers, in the style of this period, were generally made to receive that beautiful characteristic of Pointed architecture, the spire. This, in the best examples, is octagonal in its plan, and of pyramidal elevation, running to a point, or nearly so, under an angle of about 12°, the angle at the base being consequently 84°. In some cases the spire is richly crocketed like the pinnacles; but whether plain or crocketed, it is surmounted by a bold finial.

Plate LXVIII. Fig. 1.

The most perfect structure in this style throughout is Salisbury Cathedral, which, unlike any other Pointed cathedral in England, except perhaps that of Bath, was begun and finished in the same manner; and so excellent an example is it, that it has been proposed to call the style of the period the Salisbury style. Not inferior in merit, and hardly less perfect a model of the same, is Beverley Minster. That which is of later date in it is easily distinguishable; and being confined to particular parts, it hardly interferes with the unity of the composition. The transepts of York Minster are also of the first period, and so is a great part of Westminster Abbey. The fronts of Ely, Lincoln, and Peterborough Cathedrals exhibit good specimens of it. Indeed there is hardly one of all our Pointed cathedrals which does not partake of this style in a greater or less degree. It will be most generally found interwoven with and superimposing the Anglo-Gothic where that exists, and inferior to, when in connection with, works of a later period. Many of the monastic structures with which the country abounds present very beautiful specimens of this style also. Among other excellent examples of it may be particularized the chapter-houses of Lincoln and Lichfield. Those beautiful monuments which the affection of Edward I. induced him to raise to the memory of his wife, called the Crosses of Queen Eleanor, are in the style of the first period, though they verge on that of the second, and indeed mark the transition which took place in the latter part of that king's reign.

Of the Second Period of Pointed Architecture.

The style of this period, which is thought by many to be the classic age of Pointed Architecture, is described by Mr Rickman as being distinguished " by its large windows, which have pointed arches divided by mullions, and the tracery in flowing lines forming circles, arches, and other figures, not running perpendicularly; its ornaments numerous and very delicately carved." Mr Britton says that " during this period the Pointed style received its greatest improvements;" and that, limiting it to the time of Edward III., " the form of the arch then principally in vogue admitted of an equilateral triangle being precisely inscribed between the crowning point of the arch and its points of springing at the imposts." The mullions of this style clearly result from the slender shafts which were used in that of the first period against the piers dividing a number of windows. The piers being removed, it became necessary that an arch should be turned from side to side, leaving a space to be filled up in the head above the smaller arches. This was done by repeating and continuing their contours, and connecting them by gracefully flowing lines and foliations. It is indeed but an extension of the former; for in some of the early examples the mullions are thin columnar shafts having capitals and bases, and the head of the arch is generally filled up with regular figures, such as foliated circles, leaving spandrels or triangular circular-sided spaces in various parts. It is in the more advanced works of this period that the tracery becomes what may be truly called flowing. The mullion is angular and moulded, and the mouldings run all through the composition; the jamb or architrave mouldings also run through, and for the most part without the intervention of any horizontal mouldings at the impost or springing of the arch. Besides the ordinary covering cornice or drip-stone following the form of the arch, we find a moulded cornice, generally arranged pediment-wise, embracing a window or door, having crockets and finials, and resting on corbels, which are almost always masks. This may be called an attached canopy. The columnar piers of this period are nearly square in plan, and are placed diagonally. They are sometimes composed of clustered shafts, and sometimes of shafts separated by deep hollows. Their capitals are either moulded simply in rather a deep congeries, or with woven foliage under a moulded abacus. Their bases are a diminishing series of bold mouldings, supported generally by a vertical-faced octagonal plinth. The shafts which support the ribs of the roof or ceiling tracery, in the finest examples of this style, spring from rich and bold corbels in the angles of the arches, or the spandrels, immediately above the piers. The groining ribs do not adhere to the angles of the groins merely, but are set more profusely to form tracery; and rich bosses are put at every intersection. Buttresses of the second period are exceedingly various: on quoins they are mostly set diagonally. They either diminish gradually in heights or stories, and finish under the cornice, or they run through and are surmounted by pinnacles. In some cases the sets-off in diminishing are made simply with an inclined shelf; in others every set-off is formed with a pediment properly

Plate LXVIII. Fig. 2 & 3

Fig. 4 & 5, and Plate LXX. Fig. 1.

Plate LXIX Fig. 2

Plate LXX. Fig. 1.

Pointed Architecture.

enriched, and the face of the buttress is commonly ornamented with blank tracery in panels or in niches. Flying buttresses of this period are also more ornate than those of the preceding; indeed in this they became ornaments, whereas in the former they appear to have been kept out of sight as much as possible. Parapets are either pierced or embattled, and a similar variety is maintained in pediments. Pinnacles are generally square, but they stand diagonally with regard to the turret or buttress on which they are placed, their angles resting on the apices of the pediments which surmount the faces of the substructure. These pinnacles are richly ornamented with crockets and finials. Spires are less common in the more extensive works of this period than in the precedent; but in those of minor importance they are frequent, differing little, however, from the same object in works of the first period, except in being more highly enriched. Towers are richly pinnacled; but the pinnacles rest for the most part on small turrets rising from the angles of the tower itself, and seldom from projecting turrets or from the heads of buttresses, which latter are generally found to die away below the cornice. The details and enrichments of this style are too curious and complicated for verbal description, but they may be gathered from the examples.

We possess no one complete cathedral of the second period, but almost all our larger Pointed structures present specimens of it in a greater or less degree. Excepting perhaps the upper story or belfries of the towers of York Minster, which are of the third period, its west front is a model for this style, and it presents specimens of almost all its external peculiarities. The nave of the same edifice, and the interior of Exeter Cathedral, are perhaps the finest examples of the second period. The latter edifice, indeed, has the reputation of presenting a greater and more pleasing variety of tracery than any other of the same style. To these may be added the cathedrals of Lincoln and Ely, both of which contain much that is valuable. Next to these cathedrals may be placed Beverley Minster, which is not only a mine of beauty of the first, but it presents many exquisite specimens of this period also. The steeple of St Mary's Church, Oxford, is a fine example in this style of the combination of tower and spire. Many minor works in England, and several in Scotland, are excellent; particularly much of what remains of the High Church, Edinburgh, much of the remains of Elgin Cathedral, and the largest portion of those of Melrose Abbey, which, it would appear, was not excelled, when perfect, by any thing in the kingdom.

Plate LXX. Fig. 1.

Of the Third Period of Pointed Architecture.

This is that period of the style commonly known as florid Gothic. The first authority quoted with regard to the styles of the two preceding periods calls it the Perpendicular English, and says that this name clearly designates it; "for the mullions of the windows and the ornamental panellings run in perpendicular lines, and form a complete distinction from the last style." Mr Britton, however, insists that the term *perpendicular*, though perhaps proper enough, if the style could be sufficiently distinguished by the mullions of the windows and the upright forms and continuity of the panelling over entire surfaces, "gives no idea of the increased expansion of the windows, nor of the gorgeous fan-like tracery of the vaultings, nor of the heraldic description of the enrichments which peculiarly distinguished this period; neither does it convey any information of the horizontal lines of the door-ways, nor of the embattled transoms of the windows, nor of the vast pendents that constitute such important features in the third division." Although windows with tracery in them may be determined as belonging to this period, by the perpendicular and parallel lines found in the head or arch, and by the use of transoms to divide the bays into heights, yet the presence of a window of this kind does nothing towards fixing the style of the edifice generally to which it may belong; for in hundreds of cases this sort of window will be found where it is the only specimen of its age or style in the structure. Other points must therefore be attended to.

Pointed Architecture.

Plate LXVIII. Fig. 6.

The simpler arches of this style are, like those of the preceding periods, struck from two centres only; the two sides or halves of the arch are similar segments of a circle whose radius in this case is about three fourths the width of the opening. Others are segments of ellipses, and are of course struck from four centres; but some are eccentric curves, which may be drawn, but cannot be described. Many of both the latter descriptions are extremely flat or depressed, the angle at their apex being very obtuse. The ogee or contrasted arch is also found in works of this period, but this is more common in internal tracery than in external form. The modes of arranging tracery must be gathered from examples, for they possess no degree of regularity to render it possible to describe them generally in words. Mullions are richly moulded, and so are the architraves of both doors and windows; the deep congeries of mouldings forming architraves are not intercepted by horizontal or impost mouldings, but run through from the head down the sides or jambs. The angular or pedimented canopy to an arched opening in the style of the second period assumes in this the form of a contrasted arch; it is corbelled and enriched with crockets and finials as in that. Doors, however, in this style are peculiar, because whatever the form of the arched head may be, it is inscribed in a square frame or canopy, the spandrels being variously enriched. Columnar piers of this period are of almost parallelogramic form, thinner in the direction of the arches, and generally plain on the longer sides, but deeply moulded and running to a thin shaft on the outer edges. These mouldings are those which enrich the arch, there being no capital of any kind to intercept them, so that they run, as in windows and doors, all round the opening. To this, however, there are exceptions. The thin shaft which is formed on the outer edge of the pier continues through from floor to ceiling, to receive the groining ribs; and it has a thin congeries of mouldings at either end to form base and capital. The tracery of the ribs of groined ceilings of this period is most profuse, and beyond description intricate. To this also belongs the absurdity called basket groining, in which the arches are made to spring on one of their sides from a pendent mass, which, though rich and gorgeous in appearance, threatens constant ruin. Quoin buttresses standing diagonally are not so common in this as in the preceding style: in form, however, they are not dissimilar, excepting that the sets-off are plain moulded slopes for the most part, instead of having pedimented or triangular vertical heads, as in that. Flying buttresses are, like the style generally, very much enriched, and are very commonly used. Parapets are variously arranged; indeed they embrace almost every peculiarity, being either plain, panelled, pierced, or embattled; each decorated arrangement is effected by different means. Pinnacles in this style are generally square, but there are examples of pinnacles which have a greater number than four sides; in the former and most usual case they are sometimes placed with their sides parallel to those of their pedestals, and sometimes diagonally: they are of course in every case highly enriched with crockets and finials. Spires of this are hardly distinguishable from spires of the preceding period; and towers, of which there are innumerable specimens, may be known by the construction of their buttresses, and by the arrangement of the tracery in the heads

Pointed Architecture.

of their windows, as the windows of towers are generally contemporaneous with that story, or stage of it at least, to which they belong. Octagonal or otherwise polygonal turrets at the angles of buildings are not uncommon, and they generally finish with an embattled parapet. The pedestals which support the pinnacles on the angles of towers, and at the heads of buttresses, seldom have pedimented faces, as in the preceding period, but finish with a corbelled battlement, and not unfrequently send up minor turrets and pinnacles from its angles.

In the more ornate works of this style the enrichment of flat surfaces is carried to great excess, and it is generally effected by means of panelling. Niches with their canopies, tabernacles, screens, and stalls, exhibit the most exuberant profusion of ornament, for the most part effected in this manner; but we find, besides, a considerable variety of ornaments, foliate and heraldic; of the former the Tudor flower, which is a combination of the roses, is pleasingly predominant.

The only one of the cathedrals entirely of this period is that of Bath; but being generally inferior in merit to many other examples, it need not be cited. Many of the cathedrals, however, have large portions in this style, which can hardly be mistaken if the form of the arches, the arrangement of the tracery, and the mode of enrichment, be attended to. The finest west fronts of the third period to cathedrals are those of Gloucester, Winchester, and Chester; but that of Beverley Minster is by far the most perfect and most classic specimen in existence, not excepting the front of Westminster Hall, which is also of great merit, and presents a classic exemplification of most of the peculiarities of the style. Taken as separate edifices, the chapels of St George at Windsor, of Henry VII. at Westminster, and of King's College at Cambridge, are the most complete, as they are entirely and peculiarly of the third period. The central towers of the archiepiscopal fanes of Canterbury and York, the tower of Gloucester Cathedral, that of Magdalene College, Oxford, Boston Tower, and the tower of St Mary Magdalene at Taunton, are singularly excellent examples of the style. To smaller edifices, those of Wrexham and Gresford in Wales, and of St Neot's in Huntingdonshire, are particularly beautiful. Of steeples, that is, towers having spires superimposed, there are many fine specimens; but the most perfect, perhaps, in composition are those of Bloxham in Oxfordshire, and Louth in Lincolnshire: the former is most admirable rather in general than in detail. Many of the monastic ruins throughout the country present excellent specimens of this style also; indeed it is to ecclesiastical structures we must look for architectural display in Pointed architecture, as in that of the Egyptians, Greeks, and Romans. We have just specimens enough existing of the architecture of the secular structures of our ancestors to show how inferior it was in merit to that of the ecclesiastical; and if the castellated mansions of the nobility, and the palaces of the sovereigns, cannot vie in excellence with the cloistered cells of the monks, we may be well assured that ordinary domestic architecture was still more of an inferior cast.

Plate LXXI. Fig. 1.

Elements of Beauty in Architecture.

Simplicity and harmony are the elements of beauty in architecture; simplicity in the general form and arrangement of a subject, and harmony in the collocation and combination of its various parts. Without these qualities a structure can never possess either dignity or grace, and with them it will certainly possess the attractions of both. The outline, then, most conducive to beauty in architecture, is that which bounds the most simple forms. These are the parallelogramic and pyramidal, in which the lines are straight and uninterrupted throughout their whole length. The ancient monuments of Egypt, of Greece, and of Rome, offer the most complete exemplifications of this. No other than the long, unbroken line which bounds the temples of Egypt could produce an effect so grand; and no other than the simple, square, and pyramidal forms, could be productive of so much dignity as they possess. In the pyramids and obelisks of the same country the effect of this simplicity is even more obvious. In the temples of Greece, again, the same dignified simplicity is still predominant; for although in them the parallelogram and pyramid are combined, they are not confused; their mass consisting of a parallelopipedon whose ends are surmounted by vertically faced pyramids, connected by an unbroken line of ridge running parallel to the horizontal boundaries of the sides. Those of the Roman monuments which are deficient in simplicity are also deficient in beauty. Such are the triumphal arches, whose general form is broken by columns and arches which subject themselves to no commanding outline, but are all at the same time prominent features of and excrescences from the general composition. In the temples which are on the Greek model it is not so; nor is it so in the long series of arches in the Roman aqueducts, which are crowned and connected by commanding lines, unimpeded by projections or protuberances of any kind. The crucial form of the Pointed cathedral may be thought to detract somewhat from its simplicity, and so much from its beauty; but it is an aggregation of simple forms, perfectly coherent with the tendency of the leading lines in the style, which, we have seen, is vertical; and the lines are therefore not broken by the projected masses of the transepts, as they would be in the Egyptian and other styles, the tendency of whose commanding lines is horizontal. Otherwise the Pointed cathedral is a modification merely of the form of a Greek temple, with other parallelogramic forms added to it, as towers, or pyramidal, as spires. The same principle will be found to pervade the best works of the Italian school, more or less modified according to its application.

Beauty in Architecture.

Pl. LII.

Pl. L.

Pl. LX. Fig. 10 & 11.

Next to the straight line is the circular; but the greater complexity of this latter, and the variety of which it is capable, render it more subtile, and for the most part less competent to produce grand and impressive effects, except under peculiar circumstances of situation and combination. A cupola such as the cupolas of St Peter's at Rome and St Paul's in London, if placed on its base on the ground, or even on a low structure, like a large beehive, would be not merely ineffective, but absolutely ugly; and if, in the situations they occupy, the cupolas referred to were without the diminishing pinnacles above them, to bring their general outlines within that of the pyramid, it is a question whether they would possess the attractive beauty they now do. If St Paul's be looked at in the gray twilight of morning or evening, or when a mist renders its form indistinct, the impression conveyed by the mass is that of a lofty pyramid or cone, rising out of the substruction which the cathedral forms, and running off to a point in the sky. The superstructure of St Peter's is, as we have seen, more depressed, and less perfectly formed in this particular; yet nevertheless it may be submitted to the same test, and the same or nearly the same result will follow. Furthermore, let a hemisphere or an oblate hemispheroid be supposed in the place of the prolate hemispheroid, as at present, and this reasoning will be rendered more clear; for neither of those forms, even with the accessories these possess, would be as beautiful; and without them they would be ungainly deformities, as is proved by that example on the new palace in London, on the site of Buckingham House.

Pl. LXV.

Beauty in Architecture.

The cupola of University College, London, exemplifies this point also; for though its profile is elegant, and its accessories are generally good, the composition does not resolve itself into a simple form, and the result is far from being beautiful.

When the circular form is employed cylindrically, the utmost simplicity is required to be preserved in its horizontal, as well as in its vertical lines, or the result will be totally devoid of all architectural beauty. In proof of this, let the broken and dentilled columnar ordinance which surrounds the tholobate of St Peter's be compared with the noble, unbroken peristyle in the corresponding part of St Paul's. In the former the cylindrical mass is studded with a series of minute excrescences of coupled columns; and in the latter it forms a grand, beautiful, and effective compartment of the composition.

The preceding remarks do not of course apply to the interior of a structure in the same manner; for although as high a degree of simplicity is required internally as externally, similar combinations are not necessary, nor are they indeed always available. A spacious concave, of whatever form its profile may be, so that its plan be a perfect circle, is one of the grandest works of architecture, and at the same time one of the most simple, whether it occupy a compartment of the structure to which it belongs, as in St Peter's and St Paul's, or cover the complete edifice to
Pl. LX. Fig. 4. which it appertains, as in the Pantheon at Rome. In such situations it is indeed almost impossible to destroy its inherent simplicity; and being unconnected with external circumstances, it requires no coherence with any thing else, being as independent of its substructure as of its external contour for effect. Irregular and intricate forms, however, in works of architecture, whether internally or
Figs. 1 and 2. externally, will be found unpleasing. Few can admire the external effect of the Pantheon, or of the structure in London called the Colosseum, which has been subjected to the same arrangement, though certain features in both may be indisputably good. To these may be added the church in Langham Place, London, and indeed many others; but that is an egregious example in point. The complication of straight and circular in their composition, and the consequent irregular forms and undefined outlines, totally destroy both simplicity and harmony. The comparison of an Egyptian obelisk with a monumental column of the same relative size will afford the strongest proof of the superiority the more simple form possesses over the more complicate. None, however, but those who have visited Rome, in which city alone the comparison can properly be made, can duly appreciate this evidence; but London furnishes a contrast almost as much to the purpose, in the monument on Fish Street Hill, and the lofty shot tower by the south-west abutment of Waterloo Bridge. They are both of nearly cylindrical form; but the one is crowned by a square abacus, and the other by a bold cornice, which follows its own outline. The greater simplicity and consequent beauty of the latter, having regard to general form alone, are strikingly obvious.

Not only in general form and outline is simplicity necessary to beauty in architecture, but also in all its details, and even in its enrichments. In exemplification of this, a plain Greek entablature may be compared with one in the Roman style, in which every thing is sacrificed to profuse ornament; and the style of ornament in the latter may again with equal advantage be compared with that of the age of Louis XIV. of France. In the arrangement of the parts of a composition, as well as in the composition itself, simplicity is essentially necessary to the beauty of the whole; every style will afford exemplifications of
Pl. LV. Fig. 5. this also, in the comparison of the more simple with the more complicate specimens of the same. Compare the few simple and well-defined parts of a Grecian Ionic entablature with a Roman or Italian example of that order in the latter will be found a complexity and straining at effect not at all consistent with beauty and dignity, determining the comparison much in favour of the former; Pl. LIX. Ex. 3.
and so in many other cases which might be cited. That Pl. LXII. Fig. 4.
the more simple arrangement of columns at equal distances is superior to that in which they are coupled or placed only alternately equidistant, is clear from the fact that the latter mode was first proposed, and is only used to obviate difficulties, and not from choice, except in the works of the merest pretenders.

Harmony, concord, or fitness—of proportion, of form, of one part of a composition to another, and in the collocation of the various enrichments which architecture requires,—is as necessary to its beauty as simplicity. We do not speak of the agreement which should exist between the manner or character of a structure and its application, for that is purely conventional, and totally independent of any architectural consideration. The merit or demerit of a composition is not at all affected by the use to which the edifice is applied; neither would its front be more tolerable, nor its cupola less beautiful, if St Peter's in Rome were, by the course of events, to become a democratic forum instead of a papal basilica; nor is the monument of London a more or less elegant object, whether it be understood to record a triumph or a defeat—the burning of the city, or its re-edification. Harmony in architecture is that agreement which exists between its various parts, as in the relation of a column to its entablature and stylobate, in the accordance of a cornice with the elevation it crowns, and in the coherence of one part of a composition with another. It is that which exists in the common tendency of the leading lines of a structure; and it is that which blends the straight and circular in enrichment or decoration, as in the capital of an Ionic column whose square and horizontal form is harmoniously adapted to the vertical lines and cylindrical form of the shaft, by the intervention of the volutes. An inharmonious combination arises out of the collocation of the same voluted capital with a pilaster or squared pier. This quality requires a judicious arrangement of ornament. That a certain degree of enrichment should pervade the whole of a composition, and not be confined to one part of it—for instance a Corinthian ordinance, in which the columns are unfluted and the entablature is quite plain—is inharmonious; for the capitals being masses of rich foliage, are spots, having nothing to connect them with the rest. A degree of harmony must exist, too, between the solids and vacuities of an edifice. An Italian portico, with its thin and straggling columns, is an inharmonious object, for it conveys an idea of infirmity and poverty, which is not the case with one proportioned like the best Greek and Roman examples. In the front of a house, windows and the piers between them being too wide or too narrow will affect its character in this respect. The comparative size of various portions of the same composition, though they be in themselves simple and harmonious, may be such that they shall not be so in combination. The portico of University College, London, is of great extent and considerable beauty, and the cupola behind and above it is of elegant form, though deficient in another particular, as we have already stated; yet they do not harmonize—the one is much too large for the other, and their forms are incoherent.

Thus harmony has reference to comparative magnitude, strength, decoration, disposition, and proportion. To acquire a knowledge of all these sufficient to produce a worthy result, a long course of study and careful observation are necessary: but such can only be necessary to the architect; it is enough for the general student to be

able to appreciate them when present, and to detect their absence.

Principles of Architectural Composition.

These must be different in the widely differing species of architecture, whose tendencies in the one are to horizontal or depressed, and in the other to vertical or upright lines and forms; the former including all those varieties which proceed from the Greek and Roman modes of design, or columnar and circular-arched architecture; and the latter embracing those which arise out of the pointed arch, and which we have distinguished by the term Pointed. Except in the elements of architectural beauty, which must be the same in all architectural works, there is no similarity whatever between the principles which govern composition in the two species. Simplicity of form, and harmony between the parts, are as essentially necessary to the one as to the other; but instead of the leading horizontal lines required by the former, the latter is distinguished by the absence of commanding lines having that tendency, and by the presence of strongly marked lateral projections and vertically inclined lines. The rectangular figure formed by the front of a Greek temple, below the pediment, rests on one of its longer sides as a base. In a Pointed composition that order is reversed, and one of the shorter sides becomes the base; and the pediment, instead of being a depressed obtuse-angled triangle, becomes upright and acute-angled; the whole mass, moreover, follows the change thus described, so that the same figure, a parallelopiped, is set for horizontal or vertical composition, as a larger or smaller side is made the base. This being the case, it will be necessary to treat of them separately; for rules which apply to the one are totally inapplicable to the other, and the former, being of most common application, may be taken first. We shall quote the principles which appear to have actuated the Greek and Roman architects in the production of their best works, or rather the principles which those works develope, instead of citing all existing ancient works as authorities; and determine on those principles how to produce similar results in cases of which examples do not appear in ancient practice. In the same manner, we must deduce the principles for general composition in the Pointed style, from those which appear to enter into its best existing works.

Of Horizontal Composition.

Every thing tending to break the continuity of the leading horizontal lines in a composition should be avoided. The advantage of adhering to this, and the disadvantage resulting from the breach of it, are clearly exemplified in the front of the Farnese Palace, and in the flank of St Peter's at Rome. In London, too, the fronts of the Banqueting House at Whitehall, and of Somerset House to the Strand, offer similar exemplifications of the principle; the former having both the entablatures and the stylobate of the upper ordinance broken round every column, which makes the ordinances mere excrescences, and the latter preserving the leading lines continuous and unbroken throughout, to the manifest advantage of the whole composition. This applies equally to columned and arcaded ordinances, and to compositions in which neither is used; and it is as much opposed to the projection of masses to form wings and centres, whether shallow or deep, as to the breaking of an entablature or stylobate round one or two columns. Sufficient variety of light and shadow is attainable without the use of columnar ordinances at all, as the Farnese Palace evinces. But if, however, it be required to give a greater degree of importance to an elevation than can be attained in that manner, it may be produced without either attaching or insulating columns the whole extent, by means of antæ and recessed compartments with columns in them, as on either side of the gates in the north or Lothbury front of the Bank of England, and on the flanks of the churches of St Pancras and St Martin in London; but a mere pilastraded ordinance, or pilasters with an entablature and without columns, is bald, tasteless, and unmeaning, as the front of Crockford's Club-house, in London also, very clearly shows. In speaking of the Italian style, we have shown the injudiciousness of putting order above order, because of the impossibility of maintaining a rational arrangement with regard to diminution and intercolumniation. We made that, too, an objection to the elevation of the Roman Colosseum; but the practice is moreover objectionable, because of the repetition of the similar parallel lines of the entablatures, similarly projected too, which destroy the breadth a composition should possess; and because the upper and crowning cornice, if in proportion to its own ordinance, must be disproportioned to the whole elevation which takes from that member a character of grandeur or meanness, as it may or may not be fitted to its whole height. This is made very evident by the opposed fronts of the United Service and Athenæum Club-houses in London, the former of which is finished by the thin shelf-like cornice of a second order, and the latter by a crowning cornice which has some relation to the whole height of the building. In a similar manner, and for the same reason, the practice of raising lofty basements to support columnar ordinances is injudicious; and this detracts much from the merit of the front of Somerset House just referred to, by making the crowning cornice of less importance than it should be. In St Paul's this fault is partially relieved by the somewhat exaggerated size of the cornice of the upper order, and by the insertion of cut blocks, in the manner of upright modillions, under it the whole depth of the frieze. Nothing, again, should be allowed to superimpose a crowning cornice, except what may form a part of itself, as antefixæ; where, however, something is absolutely necessary, as on a bridge, a close simple parapet, as low as it may be conveniently, should be resorted to. On the principle first developed, porticoes should not be projected from the front of a building, unless they occupy the whole extent of it, as in a Greek or Roman temple, and so carry the horizontal lines unbroken to the flanks; or they should be made distinct and independent objects, to which the rest of the composition may be subservient, as in University College. A portico should moreover be considerably projected, or the surface behind it recessed, that the columns may have a background of shadow, otherwise it will be poor and inefficient. Of this the Greek temples offer a favourable exemplification; and most of our churches, and other modern edifices which have porticoes to them, prove the correctness of the principle in the breach of it. Exceptions more or less favourable certainly exist, whose superior merit is sufficient to indicate them. A pediment should never be used unless it is made to embrace the whole of the end or front to which it is attached. Numberless absurdities have arisen in Italian architecture from the injudicious application of this form; so general, indeed, is it, that the fact of a pediment existing under any circumstance in a work of that style is almost a sufficient reason for avoiding a similar use of it. Nothing is more difficult than to combine straight and circular, or otherwise bending lines, with propriety and good taste, and therefore their collocation, in general composition particularly, should be seldom attempted. It is when they harshly contrast, as in circular pediments, and in mixed compositions of columns or pilasters, with their accessories, and arches and

Pl. LXVI. Fig. 1.
Pl. LXV. Fig. 2.
Pl. LX. Fig. 1.

Composition.

their piers, that the combination is bad; but not so in the connection of the arch with its pier, so that the former be semicircular or semielliptical, and not smaller segments, in which cases they fall naturally and gracefully together. The incoherence and inelegance of contrasted straight and circular forms are very evident in the New Exchange at Paris, where two tiers of circular-headed windows are seen within a Corinthian peristyle. Circular prostyles or cyrtoprostyles should be avoided, as their horizontal lines cannot be made to harmonize perfectly with any form to which they may be attached. This however does not apply to peristyles; and both the one and the other are exemplified by the transept porticoes and columned tholobate of St Paul's. The use of coupled columns is so absurd, and they are confessedly so inelegant, that it seems almost unnecessary to denounce them. Suppose apertures, such as windows, arranged in couples throughout an elevation, with very narrow and very wide piers alternating, and both the absurdity and the inelegance become manifest: now, neither the one nor the other can be either lessened or changed by reversing the case, and putting alternately wide and narrow openings, as in coupled columnar ordinances. Columns may with propriety be put further apart when they are attached than when they are insulated, because the entablature, resting in part on the wall, is neither in fact nor in appearance made infirm by the distension, as it would be if it rested on the columns alone. All the parts of the same edifice which come into view, under any circumstances at the same time, should correspond; but insulated and attached columns of the same ordinance and in the same elevation may, under certain circumstances, without impropriety be arranged with a different intercolumniation.

An arcaded ordinance should be considered as only more massive than, and differently shaped from, a columnar, and may therefore be governed by nearly the same principles. A pier is but a differently shaped and more massive column, and the archivolt but a succedaneum for the architrave; while a bold blocking course, or a commensurate cornice and frieze, as the composition may be more or less ornate, will complete the ordinance. Under this view nothing can be more absurd than to affix columns or pilasters to the piers of an arcade to support an entablature, and certainly nothing can be more inharmonious, from the contrast which arises, as we have just remarked, between the rectangular lines of the latter, and the inscribed circular lines of the arch, as well as the incongruity necessarily attending the interspaces of the columns.

In speaking of Greek and Roman architecture, we have shown why columns should, and why antæ and pilasters should not, be fluted; and have shown also, that a certain degree of richness or plainness of surface should pervade a composition, and not be confined to particular parts of it. It will now be enough to add, that in composing, lights and shadows should not be scattered on a surface as they are on the front of the Banqueting House, by broken ordinances; nor should either be too much narrowed, as the light on the corona of a Roman cornice too frequently is, by the too great projection of the cymatium. It will be found, moreover, that shadows projected horizontally are more in coherence with the horizontal style of composition, than those which fall laterally, or from a vertically projecting object.

Columns, &c.—The proportions of the columnar orders will be best sought in the existing examples of the ancients; and those we give of them afford sufficient variety. What is deficient in one may be made up from another; and what appears superfluous in one example may be omitted, as its omission may appear beneficially to affect another. The Doric may be adopted from the Parthenon or the temple of Theseus, as the best existing models of the order. If an ungraduated stylobate be used, which should be avoided if possible, it should not exceed one diameter in height. The intercolumniation should not exceed one triglyph, as in the Greek temples, though for compositions of a generally less dignified character it may, perhaps, be extended to two. A good modern example of the Doric order, in a work of the latter description, may be seen in the small entrance portico to the University Club-house in London. The Ionic example from the Erechtheum, which we have given, may be used as a model for that order, with the same restriction with regard to the stylobate which is made to the Doric. Additional depth may with advantage be allowed to the bed-mould of the cornice, and it may be effected by the insertion of a dentilled member, which indeed some of the ancient Greek (though not Athenian) examples possess. The intercolumniation should not be less than one diameter and a half, nor should it exceed two diameters. In London this order is admirably applied in the front of an Episcopal chapel on the east side of North Audley Street; and this particular example is very correctly copied on the exterior of the church of St Pancras. The great inferiority of the Roman examples of the Doric and Ionic orders is too evident to require that what it consists in should be pointed out, and they are the models of the Italian. The Greek example of the Corinthian order might perhaps be improved by making the dentil member of the cornice a little shallower, by projecting the corona rather less, and by correcting the form of some of the mouldings of the entablature generally. If the columns be used in a prostyle or other position to insulate them, they may with advantage be made half a diameter less in height; and the intercolumniation should be made less than it appears in the original, where the columns are attached. This example has been well executed in the entrance to the Philadelpheion or Exeter Hall, in the Strand; but the pedestals and the attic are blemishes in the composition. Of the Roman examples of this order, that of the temple of Jupiter Stator is certainly the best. Its greatest fault is the too great magnitude of the cornice, of which every member, except the corona, might advantageously be restricted one tenth of its height; that which is dentilled might indeed be reduced one fifth. The projections might also be diminished in the same proportion, removing the greater diminution of one fifth in this particular from the dentilled member to the cymatium, and the ovalo under it, both of which project by far too much. The three fascias of the architrave are too unequally divided. The lowest might be made as wide as the middle one, by deducting their difference from the third or upper one. In the Tivoli example the architrave is too shallow, and so are the dentil band and corona of the cornice; and the cymatium is both too deep and too much projected. The cornice would moreover be improved by denticulating the dentil band, and by enriching the frieze with an ornament less coarse and less massive. If this example be used in a generally ornate composition, some of the mouldings of the entablature should be enriched. The parts of the entablature of the temple of Antoninus and Faustina are well proportioned to each other. The cornice of this example would be improved by giving additional height to the dentil band at the expense of the moulding above it, and by denticulating it also. The cymatium is rather too shallow, and might be widened out of the moulding under it; and both should be restricted in their projection at least one fifth. The capital of this example is poor, and its abacus is too shallow. The shaft requires fluting, and one half the depth of the upper fillet of the base might be added with advantage to the tori and scotia. The cited

Composition. Pl. LIII. & LIV. Pl. LV. Pl. LIX. Ex. 3. & 4. Pl. LVI. Fig. 3. Pl. LVIII. Ex. 11. Ex. 2. Ex. 3.

Composition.

Pl. LVIII. Ex. 4. example from the portico of the Pantheon has, like the last mentioned, the parts of its entablature well proportioned to each other. As in the Jupiter Stator example, the architrave should be more equally divided. The mouldings, too, separating the fascias, should be made less; and the superior moulding, at least of the architrave, carved, unless the frieze were enriched, and then it would not be necessary. In the cornice a fifth or sixth should be taken from every member of the bed-mould and added to the corona. In the presence of modillions, however, the dentil band is judiciously kept plain, though the moulding below it would be better if enriched. The capital of this example is as faulty as that of Antoninus and Faustina, and in the same particulars. The shaft also requires fluting, and the base might with advantage be made to spread more. The ordinance of the temple of

Pl. LIX. Ex. 1. Mars Ultor, though the most masculine, is, from its good proportions, and the bold character of its foliage, one of the most excellent of the Roman Corinthian examples. Most of the entablature being supplied from a not well authenticated source, may not be original; but that is of no consequence, if it be beautiful. The corona, like that member in most Roman entablatures, wants greater depth; and the cymatium perhaps less, and certainly less projection. In this, as in the first-mentioned Roman example, with modillions there are dentils. This is injudicious; the member would be better plain, as in the Pantheon ordinance. The architrave, which is authentic, is exceedingly well proportioned, and the column is fine in all its parts. These examples all vary in their intercolumniation, from rather less than one diameter and a half to a fraction more than two diameters, beyond which proportions, either less or more, it would not be well to go. A stylobate to the order might judiciously be adapted from the Greek; for the stilted effects produced by insulated pedestals, and even by continuous vertical stylobates, are injurious to the general appearance of a columnar composition; and the thin steps in common use detract exceedingly from its beauty under any circumstances.

There are many varieties of the foliated capital which may be used with advantage; one of the least elegant, however, is that which assumes the distinction of being called the Composite order. The example of it from the

Ex. 2. arch of Titus is one of the best, if not the best; but it will be seen, on comparison, to be strikingly inferior to the Corinthian examples, or those in which the volutes of the capital are made subservient to the foliage, instead of being distended into huge mis-shapen knobs. The entablature, too, is only an exaggerated Corinthian. If it be wished to use foliated capitals differently composed from the ordinary, it may be well to preserve the character and proportions of the entablature the same, or nearly so. Under any circumstances, however, care should be taken in composing an entablature, that it have sufficient height, and yet not be too heavy; that it be sufficiently divided, and yet not frittered; that the parts have sufficient breadth, and be not so much projected as to bury all that is below them in shadow; and that ornament be properly distributed, and in sufficient quantity, without overloading the composition with it, as in the ordinance of the arch of Titus.

If again it be wished, under any circumstances (though

Pl. LVI. Fig. 4, 5, & 6. the practice cannot be recommended), to use human figures as columns, there appears to be no reason why the entablature should be executed without a frieze, as it is in the example of the Pandroseum; and if a frieze be inserted, it should be by lessening the other parts, and not by increasing the whole, as that entablature (taking it as a model) is quite deep enough in proportion to the height of the ordinance.

Entasis in columns need not be regarded, unless they exceed eighteen or twenty feet in height; but it adds much to their beauty, and should not be neglected when they are above that magnitude. No rule can be given for its production, but it may be thus described. The shaft, instead of being the frustum of a regular cone, is the frustum of a cone whose outline is not straight, but slightly convex; so that if it were perfect, its vertical section would have the form of a very acutely pointed arch. This convexity should, however, be so slight as in the finished shaft to be hardly distinguishable. Its abuse is evident in the columns of the east front of the church of St Paul, Covent Garden, and indeed in some of the less esteemed works of the Greeks themselves. The modes of fluting in the different orders may be gathered from the examples. The flutes should be deeper or shallower, as the collocation of the ordinance may require a greater or less depth of shadow on the surface of the columns. The elliptical or nearly elliptical contour seems to be the most generally pleasing. The flutes meet in an arris on columns of the Doric order, and are separated from each other by alternating fillets in the Ionic and Corinthian.

Antæ and Pilasters.—These should seldom be used, externally at least, unless with columns, for their real use is to connect a columnar ordinance with the walls to which it is attached; and being, as they are, but slight projections from walls for that purpose, nothing can be more absurd than to give them the features of columns, either by the application to them of similar capitals and bases, by diminishing, or by fluting. The use of antæ was rightly understood by the Greeks, but not by the Romans; and their proper use may be seen in the works of the former. The examples in London of their judicious application, most worthy of remark, are in those edifices already mentioned as exhibiting good specimens of the Greek orders, in the Bank of England, and in the portico only of University College. The adaptation in these of other than the bold foliage and branching cauliculi of the columnar capitals in the Corinthian ordinances to the antæ caps is particularly worthy of notice (though they are not all of equal merit as compositions), as the Greek remains are without a regular example of Corinthian antæ, and the Roman practice is inelegant.

Pediments.—As there is no mode by which the pitch of a pediment can be determined, it must be left to the taste of the designer to be governed or not by the examples of Greek and Roman antiquity: it may, however, be premised of them generally, that those of the former school are too flat, and those of the latter too steep. The pediment of the portico last above referred to is admirably proportioned to the rest of the composition, but its pitch would be absurdly flat if applied to a tetrastyle portico. The inclined sides of a pediment are covered by a cornice similar to that which forms its base, except that all blocks, modillions, and dentils are omitted, even if the bed-mould itself be retained, and a cymatium superadded.

Cornices, &c.—Although a perfect entablature should not be applied to crown an edifice, except it be in connection with columns of some sort, or their legitimate representatives, piers, yet a single cornice, or a cornice and frieze, is not so; and it forms the most pleasing termination to an elevation in which columns are not used. The proportion of one or the other may be best found by setting out a columnar ordinance of the style preferred at the height of the elevation; and the size of the cornice or cornice and frieze thus given will aptly become it. The Vignolan or block cornice, in which the frieze is occupied by cut blocks, is exceedingly effective: it is this which Sir Christopher Wren has employed in the upper Pl. LXVI. entablature of St Paul's, and Vignola himself in the front Fig. 2.

Composition.

of the Villa Giulia. With these cornices rustic quoins consort very pleasingly, and so they do indeed with all single cornices which are of a bold character, and all such should be so.

Pl. LXII. *Arcades, &c.*—The most graceful average proportion for these is, that the opening be twice the width of the pier, and twice its own width in height to the crown of the arch. The practice of the Italian school in the composition of arcaded ordinances may be generally followed with advantage, except in mingling and confusing them with columnar. The pier is based by a deep square plinth, and surmounted by a square or moulded cap or impost, the upper surface of which is the base line of the arch. In rusticated work the radiating stones of the arch show their joints, and are cut to a uniform appearance with the ordinary surface of the wall. In other cases there is a moulded archivolt, whose width varies from an eighth to a tenth of the opening of the arch. A dropping keystone is generally used; but this very much injures the simplicity, and consequently the beauty of the arch, and should be avoided.

Doors and Windows, &c.—The most approved proportion for these apertures, also, is twice their width in height. In an elevation which comprises several tiers or stories, it is customary to make those of the lowest or ground story rather less than that proportion in height; those of the first or principal story rather more; those of the second somewhat less again; and those of the third (if there be so many) square or even lower. If, however, the elevation consist of but two, the ground story should be the principal, and its windows of the most importance (if any difference be made between them at all), those of the upper story being then less than the stated proportion in height. The modes of ornamenting doors and windows are so various, and they depend so much on the coherent parts of the composition, that it is impossible here to go into their varieties, or to give particular instructions for their adaptation. The practice of the Italian school may in this case also be generally followed, avoiding those things in it which are injurious, and referring to the Greek for the details of mouldings and ornament. The application of a columnar ordinance to every door or window, giving it the effect of a little edifice in relief, exemplified by the windows of the principal story of the Farnese Palace, must be censured as injudicious; and so must pediments of all kinds, but particularly those formed with circular lines, or lines twisted in any way, or, though right lined, not meeting in a point at the apex. In basements or ground stories windows or doors may be lined with rustic courses with good effect, though the face of the wall be not rusticated; and if it be so, no other lining is thought necessary. The windows of a principal story may be lined with an architrave, either quite straight or returning in knees at the head, and resting on a continuous blocking course below. This architrave may be surmounted by an enriched frieze and cornice, the former bounded at the ends, and the latter upborne by trusses or consoles, which may rest on or be affixed to a species of pilaster, outside the architrave, and parallel to it; if detached sills are preferred, a shorter and bolder truss may be judiciously applied below the sill, under the foot of each pilaster, to complete the composition; the architrave is generally a sixth or a seventh of the opening in width, and the console and its pilaster about a ninth or tenth. Upon no account should rustics be run through the architrave lining of a window, as on the flanks of St Martin's Church in London. A series of circular-headed windows conjoined, as in the earlier works of the Venetian school, is productive of a pleasing effect; but the large circular-headed, with two conjoined smaller rectangular windows, found in the later works of the Italian school, and called Venetian, is radically inelegant; and there is such a one in the east end of the structure last mentioned. Blank windows should be recurred to as seldom as possible; and when they cannot be avoided, they should have sash-frames and sashes as if they were real windows, otherwise they give a maimed effect to an elevation.

Niches.—There are very few cases in which these do not act injuriously on a composition, from the difficulty of making them cohere with the other parts: the usual mode in Italian practice is to give them the effect of windows, which cannot be approved of. Internally they may be used with much better effect than on exteriors. If a niche is intended to receive a statue, it should have a circular head; if a vase, it will perhaps be better straight: the plan of a niche is semicircular.

Parapets.—The pierced parapet or balustrade is not inelegant when the forms of which it is composed are simple and chaste, as piers; but the close continuous parapet is generally preferable, because of its greater simplicity, and its accordance with the principles developed in the most classic works of architecture. The parapet of a projected balcony, to give an appearance of lightness, may perhaps be better pierced; but if a stereobate continue straight through a window without projection, it should remain close and uncut, unless there exist some special reason for wishing to make the window appear so much higher.

Balconies.—These, whether continuous or broken to every window, act for the most part injuriously in a composition. In the former case they cannot be kept sufficiently under not to appear of too much importance; and in the latter they have the effect of a broken cornice or entablature. In both cases, when a balcony is above the eye, it destroys the proportion of the windows opening on it, by intercepting more or less of their height.

Proportion and Arrangement of Rooms.—Whatever the length of a room may be, it will not be disagreeably proportioned if its height and breadth are the same; and if the length may be limited, once and a half the breadth is the most pleasing. Galleries, of course, will be much longer than that proportion; and corridors will necessarily be narrower than they are high. Entrance-halls should be cubical, regularly polygonal, or circular. Access should be given to a room by the end; it should be lighted on one side, and the fire-place may be at the other end, or on the other side: if the former, there should be two doors, or one and the appearance of another, that the fire-place may not be immediately opposite to a door. Many things, however, from locality and otherwise, frequently occur to make it practically impossible to attend to such suggestions as these. In halls and saloons not commanding a pleasing view, the windows may be advantageously placed above the usual level, for agreeable effect, for light, and for ventilation. In rooms lighted from above, as the Pantheon in Rome is, a columnar ordinance may be judiciously applied; but otherwise columns and their accessories can seldom be well disposed internally.

Chimneys.—If a chimney be in the end of a room, it should be similarly proportioned, the height and breadth of its opening corresponding with the height and breadth of the room; if it be on a side, it should be somewhat wider than it is high; if the room be longer than the sesquialteral proportion, it should have two fire-places, either at the two ends or equidistant from the centre of one of the two sides. The chimney-piece should be bold and massive, not frittered into small parts and much moulded; it may, however, have its vertical faces enriched with great advantage.

Ceilings.—The ceiling of a room should be nearly plain,

but it may rest on a bold and enriched cornice, not composed like an external cornice, as it is differently lighted, but with deep covings instead of broad flat surfaces. Such cornices are highly susceptible of ornament, and they may have additional effect given to them by means of colour. In large rooms the area of the ceiling may be pleasingly contracted, and so made to appear lighter, by coving the angles altogether, and thus bringing the cornice on which it rests lower down on the walls. This mode of arrangement is used, too, in the small rooms of a lofty story, to take off from their too great height. The horizontal surface of a ceiling may be treated like a large panel, with broad borders and slight sinkings; or, if it be very large and lofty, coffering or panelling all over, with moulded or painted ornaments, will produce an agreeable effect. Domed ceilings should be coffered, especially when they are lighted from above; but if the light be from below, as in St Paul's and St Peter's Cathedrals, ribbing is far better. Heavy cumbrous masses of foliage in a ceiling should be avoided; frets, guiloches, and arabesque ornaments, are the best suited enrichments for a ceiling on which ornament is necessary.

Stairs.—In a structure whose principal apartments are on the ground floor, the staircase is a secondary consideration, and should be secluded; but where they are above the level of the entrance door, it becomes an important part of the interior, and should be of immediate and easy access. The rise of a step should not be more than six inches, and the tread not less than twelve. In a square staircase winders should not be used; and in no case should there be more than ten or twelve flyers without a quarter or half space, both to prevent fatigue in ascending, and to avoid even the appearance of danger in the descent. Winding staircases are less convenient and less pleasing in effect than those which are square and without winders. Much room may be saved, however, where it is of consequence, by using the former. Handrails should follow the character of the staircases to which they are attached; but a somewhat square form, with the sides or edges moulded, should be given to them under all circumstances, because of its simplicity, as well as the greater degree of firmness or solidity which the whole composition derives from it, both in effect and in appearance, than can be acquired for it otherwise. The handrail and balusters of an in-door staircase are indeed but the parapet of an external flight of steps, or of a terrace, executed with more lightness and a greater degree of delicacy because of their location. The balustrading, also, should therefore be characterized by boldness and simplicity, though it is indeed a difficult thing to compose with propriety, because of its inclination, and the want of parallelism between the graduating base formed by the ends of the steps and the hanging level of the coping or handrail. The first step of a staircase has a voluted or curtail end (or ends if it be insulated, as in a staircase with a double returning flight) supporting a column or newel, on which the voluted or scrolled end of the handrail rests. The steps of a staircase are wrought with moulded nosings, which are returned at the exposed ends; the under surface is either cut straight and parallel to the inclination of the flight, or moulded to form a sightly object when seen from below.

Mouldings and Ornament.—The Greek examples offer the most beautiful forms for mouldings, and the Grecian mode of enriching them is unsurpassed for beauty and efficiency. By adhering to them, and observing the manner in which they are produced and combined, it will not be difficult to produce and combine mouldings in sufficient variety for every purpose.

For ornament the Roman examples may vie with the Greek; but in composing or adapting, it is necessary to avoid alike the tendency to too great luxuriance in the one, and to poverty in the other. The remains of Herculaneum and Pompeii have furnished us with a great deal of ornament that is new and beautiful; and much that is excellent may be found on the earlier architectural and sculptural monuments of Italy of the middle ages.

It should nevertheless be always borne in mind that the object in architectural enrichment is not to show the ornament, but to enrich the surface, by producing an effective and pleasing variety of light and shade; but still, although the ornament should be a secondary consideration, it will develope itself, and should therefore be of elegant form and composition, as well as the means of producing a good effect on the surfaces to which it is applied.

Of Vertical or Pointed Composition.

The towers of Westminster Abbey are an excellent practical illustration of the essential difference which exists between the horizontal and vertical styles of architectural composition. In general form they belong to the Pointed style, and in so far cohere with the structure generally; but the running lines of the buttresses, if their quoin piers may be so called, are constantly intercepted by transverse cornices; and all the details are strangely in discordance with the character derived from the pointed arch.

Buttresses in a Pointed composition must not be considered simply as abutments to the arches and aids to the walls of a structure, any more than a cornice in horizontal composition may be thought only necessary to cover or protect the wall on which it rests. That these were the uses for which they were severally applied originally, cannot be doubted; but although such may be their purposes, we must now consider them as aids to architectural effect. Buttresses, then, are of the same use in the vertical style that cornices are in the horizontal—to give character to an elevation, by throwing a mass of shadow, to relieve it of the monotony necessarily attendant on a flat surface, however it may be pierced or enriched. The sides of the buttresses should be either quite perpendicular the whole height they have to run, or be slightly diminished, if the wall behind them diminishes, in lengths and not by inclined lines. Their faces also must run up vertically to the sets-off, and these should be in the same inclined line, and that line pointing to the apex of their pinnacles, when pinnacles surmount them. Indeed it cannot be too strongly enforced that there should be a constant tendency in the outlines of compositions in this style to meet, although the surfaces be themselves so generally perpendicular; and the more acute the angle under which they incline, the more graceful and becoming the style the result will be. The commanding lines of every part of a composition should lead through from its summit to the base. Thus, a spire or pinnacle should rest on a tower or turret whose angles are not interrupted, but never on a merely flat wall, however it may be faced with buttresses to give an apparent projection. Neither should low porches be projected from the face of a structure, for such can only have the effect of excrescences, and tend to injure a composition; nor should external doors be made but in places where the harmony of the composition is not injured by them as irregular apertures. Internally, square forms are seldom used; but piers consist of clustered cylindrical shafts, and thin shafts of the same form, lofty, and uninterrupted by crossing lines, act as pilasters. On these, capped with deeply inflected congeries of mouldings or foliage for the former, and lighter ones made continuous and breaking round them for the latter, rest the arches and arched ceilings. Flat surfaces are susceptible of high enrichment by means of tracery and panelling

Supplement.

mouldings are enriched, not by carving on them, but by rounding out foliage and other ornament in covings and other deep inflections. Corbels should not be substituted for shafts to support arches when it can be avoided; but they have a pleasing effect as supports to the dripstone or canopy of a door or window; and indeed there are many other situations in which they are almost necessary, but they should always be considered as succedaneous, and not as necessary to a composition.

To avoid glaring inconsistencies in composing, it will be well to adhere generally to the style of some particular period, and to employ the proportions and enrichments, as well as the forms, peculiar to it; but, nevertheless, a more ornate may superimpose a plainer part, so that the difference be not violent. Windows of the second period may be placed over an arched composition of the first, and appear naturally to result from it; but the transition would be so great from the first to the third, as to make the result inharmonious. It need not, however, be denied, to those who feel themselves competent to use the materials with good taste and propriety, to select matter from examples of the various periods, and make compositions not exactly in the style of any of them. With a clear perception of the principles of the style generally, which we have endeavoured to point out, and a practical acquaintance with the classic exemplars of it, such may certainly be produced; and they may as certainly be adapted to all the purposes to which any style of architecture can be applied.

Rules for practice might be made to infinity, but they are unnecessary in this case, there being no authorized modern practice, like that of the Italian school in horizontal composition, to counteract. It is but to use the forms, proportions, decorations, and enrichments, and follow the mode of combination, which appear in the examples: these, with constant reference to the principles we have attempted to develop, will be the surest and safest guides in composing and arranging any subject. They are, too, so rife with materials for general purposes, that few cases can occur in which there need be any difficulty in finding parallels. Buttresses, piers, shafts, arches, pediments, parapets, turrets, pinnacles, windows, doors, niches, ceilings, tablets, with mouldings and ornaments in great profusion,—indeed almost everything that can be required in practice,—appear in existing works of the pointed style; preventing the necessity of determining from the mode of procedure in one case how we should act in another, as the comparative paucity of materials in the Greek and Roman remains rendered it necessary to do in developing the horizontal style. (W. H—G.)

Supplement.—1853.

The science of architecture is the same in 1853 as in 1829-30, when the preceding treatise was written; and what was true in respect of architecture at the earlier date is true at the present time. But it could hardly happen that, in any treatise upon a subject so comprehensive and so widely ramified, there should not be something to explain, and to amend; and that, with longer experience, and, it may be hoped, increased knowledge on the part of the writer, there should not be something to add.

But as the foregoing treatise, published in a separate form, together with another and more purely technical treatise by the same writer, had become to some extent a text-book to the student, as well as an authority upon its subject in an established book of reference, it has been thought better,—there being nothing in its statements to unsay,—to let it stand unaltered save by the correction of a few patent errors of the pen or of the press, and to add, by way of supplement, a concise view of architecture in its broader and more catholic form, together with the results of discovery and investigation, as well as to bring the subject as exhibited in practice down to the present time.

In treating of architecture in an encyclopædia, the information of the general reader, or of the student seeking to be generally informed upon the subject as a branch of education, is to be regarded rather than the instruction of the professional student; and in an encyclopædia for English readers, reference to English, and more especially metropolitan, instances would seem to be more useful, because better known, than foreign or provincial examples. Illustration by diagrams to any great extent is practically impossible in a work which purports to trace the whole round of human knowledge, and which ought therefore to give an equal rate of information upon every subject profitable to the human mind, and useful to the social human being; but which must be itself, at the same time, kept within comparatively narrow bounds. Reference is made, nevertheless, to provincial or to foreign instances, where they are of such a character as to be generally known by published representation, so that the remarks made may be thereby generally intelligible.

The main defect of the treatise on architecture consists, in the estimation of its author, in the narrowness of its range and in insufficient reference to construction. It takes the artist's view rather than the architect's, and makes the mere adornment the prominent subject; taking the vulgar view of architecture, indeed, which does not regard the causes within, but which looks only to what may be, and too often is, the factitious outer form, leaving aside all consideration of that which can alone give consistency and propriety to the outward presentment. This is truly the vice of almost all that has been written on architecture under that name. Architecture, in the broad sense in which it really exists, and in which alone it ought to be understood, has been ignored, and the world has been content to take the shadow for the substance. Construction, including in the term the disposition of a building with reference to its uses, is commonly taken to be to the architect what the lay figure is to the painter and the sculptor,—an articulated machine upon which to hang drapery,—and it is, by the great as well as by the little vulgar, both lay and professional, esteemed, and by some designated, the common part of the art. But construction, taken in its double sense, is really the bone, marrow, muscle, and nerve of architecture; and the arts of construction are those to which the true architect will look, rather than to rules and examples, for the means of producing two at the least of the three essential conditions of building well —*commodity*, *firmness*, and *delight*—which conditions have been aptly said to be the end of architecture as of all other operative arts[1].

A true architect, who arose and flourished, and has passed away within the period that has run out since the writing of the foregoing treatise, said, with equal truth and point, in commencing a lecture on architecture, which he published in 1841, and entitled *The True Principles of Pointed or Christian Architecture*,—though the doctrine is alike true in respect of every style of architecture,—"The two great rules for design are these: 1st, *That there should be no features about a building which are not necessary for convenience, construction, or propriety*; 2d, *That all ornament*

[1] "In Architecture, as in all other Operative Arts, the End will direct the Operation.—*The End is to Build well.*—Well Building hath three Conditions; *Commodity, Firmness, and Delight.*" (*The Elements of Architecture*, by Sir H. Wotton, Knt., Part i. p. 1.)

should consist of enrichment of the essential construction of the building. The neglect of these two rules is the cause of all the bad architecture of the present time. Architectural features are continually tacked on buildings with which they have no connection, merely for the sake of what is termed effect; and ornaments are *actually constructed* instead of forming the decoration of construction, to which, in good taste, they should be always subservient." [1]

A glimmering of the truth here enunciated had led the present writer to remark, under the head "Principles of Architectural Composition" (*ante*), that "the object in architectural enrichment is not to show the ornament but to enrich the surface;" but it was reserved for Mr Welby Pugin to see it clearly and to state it fully. It is in propriety or fitness that the condition of delight which Sir Henry Wotton claims as one of the three conditions of building well, that architecture consists, and not in inconsistent devices.

The readiness of the world to accept the shadow, outward presentment, or even mere colour, for the substance, architecture, of which the true embodiment is construction, has made it the aim and pretence of the student in architecture to be an artist rather than a constructor, instead of grafting the artist upon the constructor. In the practice of the law the graces of oratory are taken to be of value only when supported by the sound learning of the lawyer; and in the practice of architecture the taste of the artist ought to be held merely ancillary to truthful disposition for structure and service.

But the soundest constructor is the most apt in the production, or the reproduction it may be, of real art. If Welby Pugin had been the mere artist-draughtsman his father was, which alone he might have been but for the superadded skill of the carpenter, and thereby of the constructor, he would not have arrived at the truth in respect of building well; nor have built so well and with such excellent effect as, in his brief lifetime, he did. The mechanician Smeaton, and not a mere artist architect, was employed to build the Eddystone lighthouse, and the means placed at his disposal being truly directed to the end aimed at, the result obtained presents a compendium of commodity, firmness, and delight. The Eddystone lighthouse is well adapted to its uses; that is to say, it is commodious, it is firm and stable almost to a miracle, and its form is as beautiful in outline to the delight of the eye, as it is well adapted to break and thereby to mitigate the force of the sea in defence of its own structure. Smeaton was in that work a true architect, the artist engrafted upon the constructor; whereas in dropping uncombined stone rubble into the Thames about the piers of old London Bridge to protect the bed of the river, and thereby the foundations of the bridge, from the scour of the already pent-up stream; and in building Hexham Bridge after the manner of old London Bridge, as to the effect of the piers upon the stream, and after the manner of Westminster Bridge as to the character of its foundations, Smeaton might have been taken for nothing more than a mere artist architect. In like manner, the botanist and landscape gardener, Paxton, having learnt to help himself in the contrivance and construction of works of architecture of a kind adapted to the purposes of his art, had become qualified to suggest the employment of a material unthought of by professional architects—though as ready to their hands as to his, and often misused by them—as the main constituent of a structure, and to devise a plan by which the material employed might be applied alike with constructive propriety, with marvellous rapidity, and so, moreover, as to produce a magical effect, in a Conservatory designed to fulfil, and amply fulfilling, a noble object, which must, probably, have failed for the time, or have been carried out in an ignoble manner, if the horticulturist-architect, Paxton, had not already himself learnt to be a constructor. And this was in default of wide-reaching knowledge of construction on the part of professional and practising architects, and so-called engineers, so far as the results of an invitation to prepare and to submit designs for such a work can be taken as evidence of the knowledge, talent, and imagination of the architectural profession; for the invitation was general, and it went far and wide, and was largely responded to even from beyond the bounds of the British Islands. The Great Exhibition building in Hyde Park, originated by Sir Joseph Paxton, possessed in an eminent degree the qualities arising from the conditions of commodity, firmness, and delight; it was most commodious for the purposes of an exhibition; it was firm enough for the temporary service required of it; and there was delight in its luminousness and in the simplicity and truth of its combinations; and all this may be said to have grown out of propriety of construction as applied in and to the material, cast iron.

The use of unfitting materials on the other hand, or the employment of fitting materials inappropriately, leads almost certainly to incommodiousness, infirmity, and offence, or some of them. The bearing towers of suspension bridges are commonly built of masonry, and being so built, are of necessity massive, and being massive they tend to narrow if not to obstruct the way,—the necessity of the construction in most cases requiring that the towers shall intercept the footways, whereby the pedestrian is compelled to take the carriage-way; or for the same cause the way is narrowed if it be but one, as in a foot bridge. In the Brighton Jetty, conventionally called the Brighton Pier, the substructure of the bearing towers is of timber in piles, upon which are raised trestle-like frameworks—standards, they may be designated,—and these are made to present the outward form of towers, as of masonry, by casing them with cast-iron plates to that effect, and as if to keep up the false character thus given to the standards, they are so arranged in plan as to obstruct the way along the floor of the jetty.

Cast iron in its proper character, and in the forms which the duty to be imposed requires it to assume, would not be more inappropriate as the material of a superstructure upon piles of timber, than a tower of masonry is; and an open structure well composed of cast iron to form trestle-like framework, would, in the case of the Brighton Jetty, have left the bridged way wholly unobstructed and convenient for use.

At Rouen there is, over the Seine, a wire-rope suspension bridge in two bays; the ropes are anchored at the banks and carried over a bearing structure which is founded on an island in the middle of the river. In this case the substructure of the bearing tower, if it may so be called, is, properly enough, and as it conveniently might be, of masonry; but the superstructure is, as to the main supports of the suspending ropes and their load, in fact of cast iron disposed as columns about the piers of arches; so that the iron structure takes the appearance of a structure of stone, whilst the proportions are those appropriate to the stronger material of which it is, and not of the weaker material of which it pretends to be. The result to the eye is what might be expected. The bearing structure which, being of iron, is sufficient to carry the bridging way, pretending to be stone presents the appearance of excessive weakness; while as cast iron, properly disposed with reference to the duty required of it, the standard would have been not only strong enough, but it would have appeared to the eye to be so.

[1] *The True Principles of Pointed or Christian Architecture*, by A. Welby Pugin, Architect, &c., p. 1.

Section I.

The practice of architecture in whatever form, and under whatever alternative designation it presents itself—whether as civil architecture in works upon and above ground to be covered from the weather, or as civil engineering in works upon and in the ground and exposed to the weather—consists in originating, designing, composing, and arranging in detail, specifying, estimating, directing, and supervising the formation, construction, and fitting for use of works, and particularly works of the nature of buildings for the use and convenience of man, and mainly of social man in civilized communion.

Originating involves the devising a practicable scheme for effecting any desired object in the manner the best adapted to the end.—A canal, a road, or a railway, is required between any two places. By the aid of hydrographical maps and by personal exploration of the country, the most fitting line the country affords may be struck out and laid down; and by investigation of the levels, examination of the soil, computation of the available quantity of water at the summit in the case of a canal, and inquiry into the cost of labour, and of the various materials necessary for the work contemplated at the place where they are to be applied—the cost of land and the contingencies connected with its tenure and occupation—the line struck out as naturally the most fit, is modified to the most economical in execution, consistently with efficiency and economy in its use.—A town, or a new quarter of a town, a new street or a single house or other building, is required; the town, or part of town, the street, the house, warehouse, or workshop, is to be considered first with reference to the essentials, *commodity*, *firmness*, and *delight*;—and it will be convenient and salubrious, or unfit and probably the seat of disease—it will be cheerful and agreeable, or dull and cheerless—and, although the commercial estimation may depend on circumstances beyond the control and not wholly within the modifying power of architecture, even wealth or poverty may result from the propriety or impropriety with which the work has been originated.

Designing includes the bringing together and combining in the most efficient manner permitted by the circumstances of the case for convenience in use, all the parts of which a work may consist, shaping the parts within themselves to the duties they are respectively to perform, or to the uses they are to fulfil; adapting the work to the materials which necessity, prudential economy, or luxury may dictate; giving, indeed, a congruous body to the originated idea. The origination of a bridge has determined its position, the manner in which it shall lie across the river or whatever else it is to be built over—the manner in which it is to be approached—the waterway, in the case of a river, that may be occupied by its substructions, or rather the waterway that the bridge must leave unobstructed—the headway that must be preserved under it, whether for navigation or for flood water, and with reference to the country above it or to its own security—the level or other inclination of the roadway, and the materials of which the bridge shall be composed, together with the general outline of its form, determining thereby the class of composition to be adopted. The design gives form and consistence to the outline—it arranges the spans, bays, or openings—proportions the solids to the voids—determines, upon close and minute investigation of the site, the depth, mass, and composition of the foundations, and how they shall be executed—settles the form and rise of the arches, and prescribes the requisite appliances in erecting them, as centering and scaffolding—shows the mode of composing and constructing the roadway, and provides all the requisite accessories in completing the work for use.

Composing and arranging in detail are further preliminary considerations, and fall strictly, perhaps, within the province of design. These comprise the artistical and constructive adaptation and adjustment of the materials in the forms and combinations in and by which they are to be placed and held together to fulfil the ends of the design—the degree of finish that shall be given to a work, and the means by which it is to be brought about, as well as the modes of combining the parts and protecting them from injury from whatever source, whether from influence within the substance of the materials to be employed, from those which may be brought to bear upon them in the use of the finished work, or from external influences in and through the atmosphere. The composed and arranged design is exhibited in clearly expressed and accurately executed drawings made to scale—the scale being in ordinary English practice some aliquot part of a foot, or of an inch as an understood division of a foot—and the drawings being plans, sections, and elevations in general and in detail, made, by colouring, or by hatching, and by written descriptions, to express the main component materials severally and distinctly.

Specifying is a describing in writing everything required to be used and applied, and the modes of using and applying all the matters proposed to be incorporated in the work, to give effect to the design, the specification having reference to the drawings, of which it is, indeed, a further expression in words; with the addition of a description of the kinds and qualities of the materials to be employed, the modes of operating upon them, the sequence of the operations, the time to be expended upon them, or within which they are required to be effected (for time has always an important influence upon the cost of a work), and the result to be produced; and this must be done in such manner as to render misapprehension or misunderstanding as nearly impossible as knowledge and perspicuity can make them.

By estimating is understood the computing the quantities of materials of their various kinds required to be used or applied in the execution of a work; the power, whether it be that derived from inorganic matter through the aid of machinery, or from the labour of beasts of draught and burden, or of men, and the labour of skilled workmen as artizans necessary in procuring the materials, and in preparing, shaping, and applying them to effect their combination in the manner and to the end proposed; and, furthermore, the cost of such materials and labour, together with all the charges and expenses proper and incidental to the execution of the work according to the drawings and specification.

Directing and supervising the execution of a work imply the instructional explanations the workmen may require while the works are in preparation and progress, and the overlooking them to see that they do properly what the drawings and specification require to be done. In the case of a contract for the execution of a work, the effective directions must be supposed indeed to appear in the drawings and specification, and so that supervision shall be only necessary to secure adherence to such directions.

"In architecture, as in all other operative arts, the end is to build well." But, with whatever limitation in his own mind Sir Henry Wotton may have made that declaration, the conditions of well building declared by himself, give a much wider meaning to it than the words are ordinarily taken to convey. Architecture in its broad and catholic sense admits of no limitation—it is subterrene as well as superterrene, formative as well as structural, and includes the general disposition of a site as well as the particular arrangement of the parts into which it may be divided. It is thus applicable to towns, or aggregations of buildings, as such, as well as to the individual buildings which go to make up the town, and ought to be applied in such manner that the general result, in building a town, shall be in accordance with the conditions, and that they shall be fulfilled in the aggregate

Supplement.

as completely as they are required to be fulfilled in each particular building which may go to compose it.

In the choice or selection of a site for a town, intrinsic circumstances,—some peculiar advantages in a commercial, or a merely pleasurable, or it may be indeed a military point of view,—commonly determine the general question, and impose upon the architect to fit it in all particulars for the contemplated purpose. Whether the site have the advantage of railway communication, or not, easy access by carriage-roads must be provided; which roads must be laid out, and set out with such inclinations proper for use as are attainable; bridges and culverts must be built to carry the roads over streams and gullies, and they must be cut, formed, drained, bottomed and metalled, or otherwise paved; quays to the river or the harbour must be arranged and formed, or embanked and constructed,—encroaching upon the tideway, or widening the waterway as the case may require; or, in the absence of natural facilities for navigation, it is a question for consideration whether artificial navigation can be obtained, and how and in what manner the arrangement of the site may be modified to render it available, or whether a railway may not be preferable to any other mode of giving commercial access to the town; the site of the town must be drained, both as regards water in the ground, and surface water, and the soilage must be taken off in a fluid state; water must be led to, or be raised by artifice within the site of a town, and accumulated in reservoirs at such levels that it may pass freely from them to all the parts of the town, and to the highest contemplated building in it. In the distribution of the parts of a town, not only are the requirements of the community as such to be considered, but the particular requirements of every class of a community ought to be provided for. There should be public markets and bazaars, and there should be also provision made for shops and warehouses, from which those who may choose to take their supplies may obtain them without recourse to the public markets. There may be within every town exclusive gardens, as in squares for the use of those who, dwelling around, may undertake to maintain them for their own use; but there should be certainly places as gardens, maintained at the public expense, open to general use for the resort and recreation of men, women, and children, of whatever class, as well as parks or pleasure grounds in the environs for general pedestrian, equestrian, and carriage exercise and open-air enjoyment. Streets, squares, and public places, should be disposed upon the site with regard to light, aspect, and ventilation; and sites for all requisite public buildings, sites for the requisite varieties of private dwellings; and places for storing, manufacturing, and commercial buildings and establishments, according to their kinds and requirements, are to be provided and arranged, and so provided and arranged as to produce the greatest possible general convenience, as well as to be capable of producing private benefit. Towards effecting these objects everything likely to be offensive should be placed to leeward, having regard to the prevailing winds. The relative levels of the lowest floor of buildings in every case to the drainage level should be settled, and provision made for the ventilation by legitimate means, of the drains of every building, so that it be not left to chance, or to the ignorance or caprice of individuals in building in detail, whether the town may be pleasant and wholesome, or be the seat of discomfort and disease.

There are certain essentials to every building which it is within the province of architecture to provide, and within the duty of the architect to secure. There must be convenient and easy access to the building itself; protection from water from whatever source and in whatever form water can present itself,—from the earth or from the skies,—by the foundation or by the roofs,—as water supplied for use, and as foul water or water the vehicle of the foulest matters;—air is to be supplied to the interior by legitimate channels from the best accessible source, and the ejection of vitiated air provided for and secured, and so that there be ventilation without injurious draughts; and light is to be admitted and diffused, so that every part of an interior may be appropriately and sufficiently lighted, and lighted from the general source directly, or with as little recourse as possible to borrowed and artificially created light; equal temperature throughout the varying seasons is to be maintained by making provision to check excess of heat at one season, and by the promotion and diffusion of heat to warm at another. Next to the general essentials—which are as much so to a penitentiary or to an hospital as to a palace—are the particular arrangement and distribution of buildings according to their respective uses, with reference to the demand which the use may make or impose. But the uses of buildings are so various, and the requirements of each particular use so different from those of every other in all the classes of buildings, while every individual building of a class may be forced into peculiarities of disposition, dictated by site and other circumstances, that no general rules can be laid down for the design of buildings in classes, or severally, without running too much into detail for the pages of an encyclopædia. These are, or they ought to be, the special study of the architect, the merit and value of whose services consist mainly, indeed, in giving special effect to the general requirements in a congruous manner, and at the smallest cost consistent with efficiency.

It will be necessary, however, to add in this place some observations upon matters which, though general in their nature, are of particular interest to every community. Whether it be in laying out a new township, or in adding to a town, provision should be made for securing that it be done in such manner as may best tend to secure to it commodity, firmness, and delight, or, in other words, the health, comfort, and safety of the future inhabitants. And first, as to the carriage roads leading into and out of a town. No such road should be permitted to have a greater inclination in any part than one in thirty, such being the maximum at which ordinary four-wheeled carriages will remain at rest upon a well-made road surface. The width of the carriage roadway, clear of any side drains, should be such as to permit three carriages abreast, taking one to be standing on one side or the other, and two in motion, meeting or passing. Eight feet should be allowed to the carriage at rest, and ten feet to each of the carriages in motion, making twenty-eight feet as the minimum width between the water channels, or at the least thirty feet clear between the footways; for there ought to be to every such road a footway on each side, and each of sufficient width for four persons, two and two meeting, to pass abreast; and this requires eight feet at the least, so that there should be in the whole little short of fifty feet of public way wholly devoted to the public in what may be termed the country roads about a town where there are no houses, or but few, before which carts or carriages of any kind can be required to stand.

In laying out a town, there need be no mere lounging places provided, such as the paved area of Trafalgar Square in London, or as the *Place* so common in the towns and cities of the Continent. Markets should be provided for in sheltered and inclosed buildings, and not be held in a *place*; and a more than equivalent for the *place* or even the village green ought to be provided for outdoor recreation, and, it may be, rest; but wholly irrespective of business. To this effect plots of from five to ten acres each, making in all not less than one-tenth of the whole area, should be reserved in laying out a town, or in adding to a town; such plots being so disposed as not be more than a short half-mile apart, or so that there shall be one such plot within less than a quarter of a mile (a sufficiently long walk at once for a child, or for a woman or a girl carrying a baby) of every domicile; and every such plot inclosed, but accessible on every side,

and laid out in the best manner to make it a pleasant resort at all times for men and women seeking rest or healthful recreation, and as a play-ground for children. With such a provision in a town, idle men and boys may be reasonably required by the police to "move on;" and with almost equal advantage to children and to the community at large, the trundling of hoops in the streets may be prohibited; whilst river or sea-side quays for business, or terraces for pleasure, need not be the permitted haunts of thieves and beggars. Out of a ten-acre plot (the size of the whole area of Russell Square in London,—and about that of Lincoln's Inn Fields, up to the inclosures before the houses), one acre disposed in four distinct quarters of an acre may be assigned to the four essential requisites of every hundred-acre area in a town—a church, a school, a library with reading-rooms, and a building to contain baths and washhouses; one at each of the four corners of the Town-Garden, in its own quarter-acre plot, and each communicating directly with the garden as well as with the streets by which, if houses or other buildings front towards it, the garden should be belted, without taking them out of the ten-acre area. The town-garden need not supersede the square and its garden, which may be formed, and the garden maintained in all its exclusiveness, with great public benefit, wherever the prospective demands of a future population may seem to require squares in connexion with the streets, by which and by the buildings fronting to them, the greater part of the whole area will certainly be covered. Nor need the town-garden vie with the square-garden in the relative extent of its plantations, or in the picturesque disposition of its paths. It should be laid out with broad walks, and hardily-turfed lawns; it should have a fountain, and trees should not be wanting; upon the whole, more like Hyde Park, the Green Park, and the public grounds of the Regent's Park, than like the too elaborately beautiful grounds of St James's Park. The town-garden should not be too delicate for cricket and quoits; nor should it be supposed to render the suburban park a superfluity: the town-garden for children in the day, and for work-day evenings for men and women, and the park for holidays.

The courses or directions to be given to streets must be greatly influenced by the circumstance of the locality, whether it be plain or hilly, and greatly by the climate, whether sunshine or shade is more to be desired. No general rule in this respect can be laid down; but having reference to the high latitude in which the British Islands are placed, and the consequent obliquity of the sun's rays at all seasons, without great intensity at any season, the light and heat of the sun are to be sought and not to be evaded; and these are more equably diffused, and the roadway exposed to the sun's rays more certainly, the more nearly the direction is that of the meridian. Perhaps, however, it is of more importance that buildings of whatever kind in which human beings are to live or to labour, shall be so disposed, that every room in every such building shall be capable of receiving the rays of the sun at some time in the course of every day that the sun shines.

The width of a street—and by the term street is intended any line of communication, whether adapted for carriages or not, in and through a town having houses or other buildings fronting to it on both sides—ought not in any case to be less from front to front of the buildings, taking an even course, than the height of the buildings, the dimensions of which—the street being once formed with such limit to its width—it ought not to be permitted at any time to exceed, without setting the higher buildings back accordingly. To this effect it is necessary to determine in what manner the height of a building is to be ascertained, the object in view being the due ventilation of the streets as a means of assuring a sufficient flow of air to the buildings, whereby they in their turn may be duly ventilated.

Take a minimum width for a street—say 30 feet—as a horizontal base line transversely of the street, and at a level, say one foot lower than the level assigned, in manner hereafter described, to the floor of the lowest story of the contemplated buildings. Erect a perpendicular line upon each end of such base, and bisecting the inner angles, draw lines which—the angles being right angles—will of course intersect the opposite perpendiculars at the height of 30 feet, the limit in height of any buildings standing up to such lines at the limited distance of 30 feet apart; the diagonals drawn out will limit the heights of the opposite buildings as to the roofs or any erections upon the roofs, beyond the perpendiculars. This rule is applicable in like manner to any greater width than 30 feet; but it will be seen that the rule imposes no limit to the height of any building standing in the narrowest street, if the front be set back at the level of the street, or be in any manner arranged by building terrace-wise; or in any other manner to the same effect of falling wholly under the diagonal line drawn from the opposite extremity of the base. Lofty chimneys, towers, and such like erections, of small extent in plan, should be admitted exceptions to such general rule.

The drainage of a town must be settled, and the levels determined throughout the course of every street, square, or other place, before the levels of the road surfaces, and of the floors of the lowest stories of buildings, can be fixed, so that they may be prescribed; but it must be obvious, that no street should be formed, in the technical sense of the term, by making the road at such a level that it cannot be efficiently drained. In like manner, as regards any building; every building should be placed at such a level that the floor of the intended lowest story can be efficiently drained, and in all respects relieved of fluid matters by the means provided; *and the means of efficient drainage should be made, and be in a condition to operate, before a building to be relieved is begun to be built.*

The widths of streets for the purpose last above referred to are to be considered as minimum widths, and irrespective altogether of the widths which ought to be imposed and required in respect of the roadways and footways, as means of communication and of passage in, through, and about a town.

A minimum width of 30 feet from front to front of buildings, ought to allow of no more than a single-line carriage-way in short lengths, or with turning and passing places; such single-line ways being necessary to give access for carts in the supply of fuel and other heavy matters, and for the removal of solid refuse, as cinders, ashes, bones, and other hard rubbish. Shops requiring frequent supplies by carts, and making their deliveries by carts, require greater width of carriage-way, and consequently greater width of street. As the demands of the carriage road for width increase, so do those of the footway; for shops making a show of their goods attract the attention of passers-by, and thereby tend to cause obstruction. Houses built as private dwelling-houses, in streets which are leading thoroughfares, or which become such, may be turned into shops; and when this is done, the space usually retained in towns between the footway and the house should be, for the reason stated, given up to the footway. In respect of the carriage-way, however, no street being, or being in a position to become, a much-used thoroughfare, ought to be of less width from footway to footway than sufficient for four carriages abreast, reckoning one to be standing on each side, and three to be in motion; for if only two be provided for, as in motion, the fast will be checked by the slow, and the whole traffic of a street be interrupted. Space for two standing carriages at 8 feet each, and for three in motion at 10 feet each, make together 56 feet as the least width that should be given to the carriage-way of a leading thoroughfare in any town. Any addition to this should be by 9 feet at the least, or it will add nothing to the convenience of the road. The footways to such

a street, where the houses are private dwellings, may be taken at three couples abreast, or 12 feet at the least, and where they are shops, at 16 feet, allowing 4 feet for loungers. Any bridge occurring in a town ought not to require the carriage-way or road to be as wide, by the two stopping carriages, as the roadways in the streets leading up to it.

The relief of a town from water in the ground, if there be any—of the water that will fall upon it in the form of rain, hail, or snow—of the waste and refuse of water raised or supplied for the use of the inhabitants, in whatever condition the refuse may present itself, must, so far as regards the mode of relief, depend, in the first instance, upon the circumstances of the locality. If the choice of a site for a town, or for an addition to a town, lay between one from which all fluids could be passed away by gravitation, and another the general level of which was so low with reference to the means of eventual discharge that nothing could pass off in a natural course, the inducements to prefer the latter to the former must be great; but cases do nevertheless occur, and when they do occur, means must be applied to remedy the defect. London, in its great extent, contains many varieties, or rather instances of many varieties, of soil and surface; and it seems desirable to show somewhat in detail to what an extent natural deficiencies have been exaggerated in that notorious example of folly and neglect, and so to teach by warning. Suffice it for the present purpose to suggest, that the main considerations in providing for the relief of a town from water in all its forms and with all its concomitants, whatever the means of eventual discharge may be, are,—first, whether there is water in the ground so near the surface as to require to be tapped and kept down; secondly, whether the water falling from the clouds upon the surfaces of the roads and streets, and carrying gravel, sand, silt, and other heavy matters, either not soluble in water, or incapable of being held in suspension sufficiently to be carried along by the obtainable current in a reasonably well-formed drain, but inoffensive, shall be passed into special drains forming a separate system; and, thirdly, whether the rain-fall and other surface-water shall be passed into the system of drains necessary to relieve the buildings of the fluids which, coming through and from the habitations of human beings, are, though foul and offensive, for the most part soluble in the water with which they pass away. It is in favour of the separate system, that surface-water (and water falling upon the roofs of buildings in towns may be to a great extent treated and passed away as surface-water), being taken off at a higher level, may often be discharged by gravitation, that is to say, by natural fall, when house drainage, which is commonly at a lower level, cannot be so. Moreover, surface-water may, without offence, be discharged into rivers and other water-courses, whilst the fluids from houses, being foul, ought not to be turned into any far inland waters, and certainly not into any tidal river far from the sea, if they can by any economical possibility be otherwise disposed of. There can indeed be no reasonable doubt, that if the circumstances of any case be such as to permit the discharge of surface-water, or any considerable part of it, by gravitation, it ought to be so discharged, though it may involve the necessity of a separate system of drains; cloacal waters being permitted to pass down to a low level, though it be to be lifted again by artifice, rather than allow it to contaminate the surface-water, and involve the necessity of lifting this also. But there is the further and important reason for keeping the two kinds of drainage-water separate, even if they must pass at or to the same level, and that a low one. The surface-water being necessarily charged with heavy matters, and commonly taking up lime and other cementitious matters with silt and sand from the roadways, a concrete is deposited in slow-coursed drains, which requires to be removed by manual labour.

Thus, when cloacal drainage and surface drainage go together, the drains must have a greater fall than the former alone requires, to hurry on the surface-waters with their heavy concomitants, and to lead both down to a greater depth than either would require if separate; and this last is the case with London.

Until within the present century, the common sewers of London received surface-water alone. Cloacal matters were not admitted into them, but human ordure and other dejecta fell or was thrown into cess-pools dug deep in the ground; and as London in the eighteenth century hardly extended beyond the limits of the dry gravel bed, the fluids were in a great degree absorbed, and the more solid matters were removed under the name of night-soil by hand-labour, and carried away in carts and applied as manure. But as the clay land became building land, and as the water-closet came into general use, the gravelly subsoil could not take up the increased quantity of fluid matter, and the clays of course refused to receive them at all; so that it became necessary to provide for the discharge in a fluid state of the matters dejected all together. This is done, so far as it is done, by drains into the common sewers, which have thus become cloacal vents, as well as conduits for waste and surface water. As more capacious sewers are found necessary for this double duty, such have been built, and are constantly in course of building, and at such depth that houses may be relieved by their drains of waste-water, and of refuse soluble in water, while the roads are kept drained by the same conduits of their surface-water. The result of such deepening, however, is, that to a large extent the outfalls of the sewers are below the level of high tide in the Thames and its confluent creeks; so that the commingled waters in the sewers are penned back to await the ebb, when the sand, silt, and other heavy and insoluble matters which the surface-water brings from the roadways deposit, and form a concrete which no force of any backwater will wholly remove and carry out at the reflux; and this it is which constitutes the great difficulty in relieving London, and in providing for the discharge of its cloacal refuse—whether for use as manure, or into the river as waste—so much below London, seaward, that it shall not return with the tidal flood to or within the inhabited area. A separate system of drains at the higher level, for the surface-waters, would discharge them with their heavy but inoffensive accompaniments from over three-fourths at least of the whole metropolitan area into the river at high tide, from which the latter return in the valuable form of sand and gravel; but it may be said to be now impossible to revert, and to form a separate system, so many places have been laid out and built upon at low levels upon the faith that what is permitted is entitled to protection. Nothing remains, therefore, but to continue the present abominable condition of London as to the discharge of its cloacal refuse; or to make tunnelled ducts for the commingled sewerage at a depth below the lowest level to be relieved—and practically very much below even that level—and the constant employment of costly artificial means for raising a most unnecessarily large quantity of matter, fluid and solid, from such low level to a level high enough to allow of their discharge without offence; or, as a further alternative, by separating the heavy and insoluble matters from the commingled fluids before they pass down into the low level ducts, where these alone may be very easily dealt with.

The existing practice is condemned, and judgment has been passed upon it, but execution is delayed for want of a feasible scheme for a plan by which to supersede it. Scores of schemes professedly to that effect have been prepared and submitted to the Metropolitan Commission of Sewers in a foolishly invited and unwisely answered competition, but none of such schemes were thought by the commissioners for the time being likely to effect the object sought in an efficient and satisfactory manner. Failing in a general competition which had, nevertheless, produced schemes from

Supplement.

some men of large experience in sewering, the Commissioners of Metropolitan Sewers instructed their chief surveyor, whose experience is understood to have been that of a supervisor of railway works, to devise a scheme; and he produced one which overcomes none of the inherent difficulties of the case, whilst it presents new ones of its own creation. No available scheme has yet been promulgated for separating the heavy and insoluble matters from the fluids before the precipitation to a deep level of either; and it is to this object probably that attention must be directed. But speculation upon the mode by which success may be attained in a particular case is not matter for an encyclopædia; our object is to show, by the miserable example of London, what ought to be avoided, as a mode of indicating the more clearly what is to be aimed at in providing for the relief of a town as a matter of architectural practice.

The considerations which lead to the choice of sites for new towns are seldom those which have regard to the personal accommodation of future inhabitants. Neither pleasantness of position, nor salubrity of air and dryness of soil, will at any time prevail against commodiousness for the trade or manufacture whereby the community to be established may obtain the means of living and of becoming wealthy. Even facilities for defence are in modern times made secondary to the objects stated, with the certain conviction that wealth can always provide the means of defending itself. The province of architecture is, so to dispose and so to form, that the advantages which dictated the site shall be rendered available and enduring, and that any defects in site, soil, or position shall be remedied—that is to say, so far as artful disposition and skilful operation can bring relief or lead to cure. In like manner as regards the increment of ancient towns. Towns outgrow the sites upon which they were first established, and widen upon soils and at levels which possess none of the advantages which may happen to attach themselves to the ancient site. Whatever were the inducements which led to the first establishment of a town on the site of the city of London—whether the facilities which it presented for defence, or for commerce, or both; or the beauty of the situation, and of the country about and within view from it; or the excellence of its soil—dry, but covering water of the finest quality—there can be no doubt that its facilities for commerce have prevailed, and that they have made it the centre of a province rather than the heart of a metropolis. But in widening as a town, London has outgrown the beautifully environed high ground, with its deep bed of dry gravel, and brought within its area cold clays and low marsh lands; so that it has long become a subject for the application of all the resources of architecture in its most extended sense, and with all the applications that it can bring in aid.

Sir Christopher Wren's scheme for rebuilding the city of London after the great fire, included every consideration that in his time was recognised as essential to "commodity, firmness, and delight;" and it may be believed that Sir Christopher's plan for re-distributing the site, with a view to fulfil the conditions which had been already laid down by Sir Henry Wotton, was not carried out, only because the case was one of *re*-building, not of building; the site had been cleared, but the rights to the ancient though ill-disposed seats or sites remained. The city was refilled with buildings, and many of them were by the great master in architecture himself; but it was not rebuilt architecturally—the buildings may have fulfilled, and certainly many of them did fulfil, the conditions of well building, so far as they could be fulfilled in a town which had not been, as a whole, submitted to them; and the city of London remains to this day, and will remain—notwithstanding the millions devoted at the expense of the metropolis to "city improvements"—a monument of bad architecture.

An urgent reason prevailed against the application of the great architect's plan to the site of the devastated city in the latter part of the seventeenth century; but there is no good reason whatever why the London that has grown up since that time around and about the city, upon the suburban gardens, fields, and marshes, should have been absolved from all wholesome rule in respect of the great conditions of catholical architecture.

Reverting, however, to the city itself, it may be remarked, that under a crushing despotism, commodiousness and delight were firmly established in the capital of France, when its ancient limits were to be extended, by a broad belt of almost park-like avenue being formed upon the site of the demolished fortifications; whilst the civic body that built an obstruction,—which is by the same body still retained,—upon the most crowded thoroughfare in Europe, wherewith to exercise their useless and now unmeaning and absurd power of shutting a door in the sovereign's face—whilst the corporation of the city of London, in the plentitude of their freedom, when they demolished their city walls and filled up the moat with the rubbish, covered the new site so obtained,—not with broad avenues for commodiousness and delight,—but with lanes, courts, and alleys; unless, indeed, Houndsditch is to be called a street. Smithfield might have been a park, or at least a garden connected with Tower-Hill by an equivalent for the Boulevards of Paris, at no cost but that of a little self-restraint on the part of the corporation. Fleet-Ditch might have been converted into a dock with broad quays locking into the river at the south, as the Grosvenor Canal further west now does, and capable of being extended inland as necessity might dictate or convenience require, and so as to deliver fuel and other heavy goods east and west, to the protection of the heart of the town from the heavier traffic north and south, to the present time and for ever. Elevated viaducts thrown over the valley of the Fleet would have connected the main lines of street running east and west; so that the means of personal communication would have been uninterrupted by, and have left uninterrupted, the trade of the lower parts of the sides of the valley and the commerce upon the quays of the dock.

It may seem useless to speculate in this place upon what might have been done in and for London a century and a half or two centuries ago; but there are many old towns and cities which hardly yet extend beyond their ancient boundaries, but which are likely to be subjected to the same process of extension, and are susceptible of improvement in like manner as they become extended. It is, indeed, to the extension of towns and cities by the bringing within the inhabited area of lands not heretofore built upon, and to the formation of new townships, that such observations are more immediately applicable. It may be said with no exaggeration, that the city of London has been twice rebuilt since the great fire, and with no improvement in its condition as it regards commodiousness, that has not been more than counterbalanced by the being hedged in on almost all sides by suburbs in which all the ends of architecture are coarsely and vilely set at nought. Hundreds of acres of land have been, in the vulgar sense, built over, and scores, if not indeed hundreds, of acres more are yearly added to London; every owner, doing what may appear to him likeliest to turn the land to his own immediate profit,—the legislature caring next to nothing for the manner in which such increment is made.

It is only natural that a man possessing land should desire to turn it to the best account, and it is not to be expected that men who possess, whether as individuals or as corporations, should do otherwise in adding their lands to the area of a town than the natural impulse leads them to do. Any man possessing, or having the authority of an owner over land in or adjacent to London may cover it, or

Supplement.

cause it to be covered over, with buildings of any sort or size, and so covered as to leave nothing upon which the foot may be placed, except certain strips which as streets and alleys are necessary, as means of communication, to the application to profitable use of all the rest; and every possessor of available land does so. It is true that in "covering" the land small plots are here and there laid out as gardens, but this is done only when the sacrifice is more than made up by the greater rent obtainable for the building sites which front to such plots; for the gardens are inclosed, and are necessarily, and indeed properly, kept for the special use as pleasure-grounds of those who pay for the use in the rent of their houses, and in rates for maintaining them. These gardens are not for the use of the public, nor even for the occupiers of other parts of the same estate, which are laid out in streets, alleys, and mews; and except so far as such gardens are open spaces and pleasant to look at, their sites are, for the rest of the community, "covered." And thus the whole surface of every acre brought within the inhabited area of London is covered or otherwise occupied; and in such manner, as regards the community at large, as to render every garden and every field turned into building land worse than the land of Egypt was under the plague of locusts—for that plague was temporary—the land is darkened that one cannot see the earth.

But the land in and about London being devoted to the purposes of building, the legislature has provided that all buildings shall be inclosed with walls, and with unmitigable stringency, that all inclosing walls shall be built of brick or of stone, without any regard to the necessity or even the propriety of such an imposition in every case; and provision is made for securing the efficient separation of adjoining buildings, that each building may be protected from fire in the event of fire occurring in the next to it. But while the law is to some extent judicious in its provisions in that respect, it leaves builders at liberty to make each separate building dangerously susceptible of fire, and ready to burn; and so to a large extent London buildings are built and rebuilt. The legislature has, moreover, made some provision to check the narrowing of existing streets in London, by projections from and before buildings to that effect; but this has been rendered nugatory by an ill-advised and wilful controlling administration, and the abuse prevails. Nothing is imposed, however, in respect of the ventilation of buildings; and every building, whether for habitation or otherwise, and whether for occupation constantly as dwelling-houses and hospitals, or temporarily as churches, chapels, courts of judicature, theatres, or other places of public resort, which are all liable to be crowded, may be made as unfit for its purposes in respect of salubrity as the most ignorant or the most wrong-headed person engaged in building may choose or chance to make them; and so to a very large extent they are made; that is to say, without any rational provision for certain and wholesome ventilation. Not that London houses are left wholly unprovided with means by which air may gain access to their interiors, and both the law and necessity act together in most cases to insure the provision of such means. Costly sewers are built under the streets to receive and carry off to some outlet for discharge waste and cloacal waters; and as every building requires in a greater or less degree relief in respect of such matters, drain pipes are laid from most houses, as a matter of necessity, to such sewers, whereby a free passage is obtained for air from or by the common sewer to the interior of every house so connected with it. Air passing through such a duct into any house, cannot fail to take with it whatever volatile gases it may encounter in its course through the sewers, and the connecting or house drains; and there can, perhaps, be no doubt, that air so commingled will be more or less tainted. But the law not only permits such conduits to be established, but, by its administrators, causes holes, curiously designated *ventilating shafts*, to be made from the roadway of any street under which a sewer may pass, down into the sewer. These ventilating shafts are grated over, and when the gratings are not choked up with stones and mud, air and road stuff go down together by them into the sewers; that is to say, air goes down when there is a down draught, but in the absence of such a draught, faint but foul gases rise by the "ventilating shafts" to taint the air of the streets for the summer ventilation of the houses by their open windows. Down draughts prevail in winter time when fires are burning; for, windows being most reasonably kept shut when fire is required for warmth, and fires requiring air nevertheless, this requisite is commonly obtained by way of the house-drains from the sewers, and hence the down-draughts by the ventilating shafts; and from this cause it is, for the most part, that the air of the metropolis is at all seasons in a condition to induce fever. The foul air of its sewers and drains is either drawn into its habitations, or vomited into its streets.[1]

But London does not stand alone as to these matters. Sewers commissions and Boards of health are multiplied throughout the country, so that hardly any town of any importance in the British Islands can long remain without the control which such bodies bring with them; but neither the science nor the practice of these bodies, nor any combination of both, has yet devised and brought into operation any system by which towns may be at once purged of the filth and eased of the foul air, which arise as surely in human habitations as in rabbit-hutches and pig-sties; nor does it appear to have been ever imagined by the legislature, by whose authority such bodies act, that it is as necessary to health that every dwelling should be provided with (to use the cant term of the sanitary empirics) an unintermittent supply of fresh air, and means by which the spent air shall be certainly ejected, as it is to insist upon an unintermittent supply of water, and the ejection of that which had answered the ends of its introduction.

It is not enough to build sewers, even if every sewer have a proper discharge, while men may, in extending a town, form streets and erect buildings in such manner and at such levels that neither roads nor buildings can be relieved by means of any existing system of sewers, or by any sewer that can be made to lead to a proper and legitimate issue; nor is it enough to make a complete and efficient system of sewers, unless they are by legitimate means thoroughly ventilated; nor is it just to the community to allow house-drains to enter a common sewer unless such drains are first made free from the foul air which is a necessary consequence of their use; nor to the future occupiers of houses to allow the drains to be left by the builders in a condition to retain foul air; nor again ought any building to be capable of being used for any purpose involving occupation by human beings, unless there be that perfect ventilation as well as efficient drainage without which no building can be properly fit to live in.

The privilege of being a member of a civilized community is purchased by a concession, whether willingly or unwillingly made, of many natural rights; and the privilege of benefiting

[1] "In fact it [drainage] has become a science, and all manner of experiments, we read, are being made in it. Yet in spite of all our proficiency in the art, and of our many resources, it is acknowledged that nothing can be fouler than the sewerage of London; that through the gratings lately opened into them, in obedience to some law of science, there comes forth a most noisome and poisonous vapour; and that, melancholy to relate, five persons fell victims in one day, this year, to the pestilential breath of one of these scientific receptacles." (From "*Essays on Various Subjects*, by His Eminence Cardinal Wiseman." London, 1853.)

Supplement.

by the industry and activity of the general community of which one is a member, ought not to be conceded without an equivalent to the community for the benefit obtained through and from it. The breath of heaven is the equal right of all; and it is the duty of society to itself, to take care that it comes unrestrained and untainted to all its members, so far as human means and appliances can do so consistently with the uses of human beings living in community. Society is bound, therefore, to insist upon every man conceding so much, at least, in respect not only of his house, but of every room in it, as shall be necessary both to secure to him his right as a human being in respect of wholesome air, and to prevent him from being a nuisance to the community of which he is a member, by condensing impurity within his dwelling, or doing anything else to vitiate the air of the locality. But it is of no use to provide means for the internal ventilation of dwellings, if buildings are so crowded together that they by their own mass prevent the due circulation of the outer air, and the change thereby in its condition which is essential to its wholesomeness; and it is a mockery of justice and propriety to call upon men to make sacrifices for what society fails to secure in return.

The right of human beings to move about upon the face of the earth which is given to man to occupy, cannot be exercised by him in a social state without restraint as to time and place. When man has, as he was commanded, subdued the earth, he is bound to limit himself for the common good to such use as may be consistent with the privilege of dominion; but he may not give up the means by which he lives to fulfil the ends of his creation; he cannot give up air, for without it he ceases to live, and he may not surrender the means of wholesome exercise, for without it he cannot have that without which life itself is a burden. When men congregate in communities, they are bound therefore—that is to say, society in the aggregate is bound—to provide not alone that the breath of heaven shall come unrestrainedly and untainted to all its members, but that the power to move about upon the face of the earth they occupy—to the extent, at the very least, of what is necessary to healthful exercise and recreation—shall be also fully retained. Human beings must not be so crowded together that they have not air, and wholesome air, to breathe, nor ought the habitations of human beings to be so crowded together that there is not space about or near to them for wholesome exercise.

But the rights of property interfere, and the owner of the land claims to dispose of the site in such manner as he may think most likely to conduce to his own interest. The owner of land, like the individual who is to occupy it to his profit, must make such concessions as it is the duty of society to require in permitting him to turn his land to profit in a manner affecting those conditions which are essential to the life and health of its members, whether present or prospective. The rights of property are to be observed, but the duties of property are to be performed; and if so under ordinary circumstances, how much the more under such circumstances as those herein contemplated. It is through and by the industry and activity of its inhabitants that a town requires extension; and as the land over which the extension may take place increases in value by the operation of such industry and activity,—and to a far greater extent than if the soil had been suddenly found to contain gold,[1]—it is the bounden duty of the legislature to take care, and by all reasonable imposition and restraint to provide, that the application of lands to such profitable account shall be made with due regard to the uses out of which the profit is to arise. The legislature is not justified in standing by until new interests have been created by the application of capital to the lands which environ a town, as they present themselves for absorption in it, and then to tax the community at large to buy up and clear off, at a huge expense, large plots here and there, at long distances apart, and from the centre. Plots of reasonable size, as hereinbefore set forth, ought to be claimed and retained as the duty of the property to the community whose industry and intelligence give such largely enhanced value to the rest, and as essential to the proper application of the rest to the purposes of a town.

If out of every 100 acres of land added to London within the present century alone, a tithe only had been claimed and set apart as a town garden, and maintained as such by a rate upon the inhabitants of the 90 acres distributed in streets and occupied by buildings, it would not have become necessary to obtain at an enormous outlay sites for recreation and exercise remote from the courts and alleys occupied by the labouring classes, and therefore practically useless to all but the few close at hand, as play-grounds for children, and places of resort for men and women who live by hard work, and who cannot afford carriages to convey them to Victoria Park or to Battersea Fields.[2]

For the same reason that as the community give enhanced value to lands as they become available for the increment of a town, the public may claim as a right, not only that such concession shall be made by the obtainer of the benefit as that last above indicated, but that the rest shall be so disposed, so prepared, and so occupied, as it regards streets and buildings, and that the buildings be so arranged, built, and relieved, as to secure the health, comfort, and safety of the future inhabitants; and it is to such effect that, as hereinbefore set forth, architecture, in its catholical sense, should be applied and enforced, by the authority of the British legislature on the part of the British public.

Section II.

The further explorations in Egypt, the discoveries in Asia Minor, the almost astounding exhumations in the valleys of the Tigris and Euphrates, the results of continued inquiries, by excavation and otherwise, in Greece, Italy, and other parts of Europe less fertile in historical antiquities, and the tracking out of remaining monuments of undescribed peoples in Central America, have tended greatly, by the illustrations obtained therefrom, to correct and improve, as well as to widen, our knowledge of the earlier history of the human race; of the condition of the mechanical and manufacturing arts; of some of the arts of design; and generally, to make us acquainted with a barbaric civilization to be always wondered at and sometimes admired. Among the remains of earlier and later antiquity thus within a recent period brought to light, there is much to confirm, and nothing to contradict, the theory propounded in the foregoing treatise of the origin of conventional architecture, or architecture in the narrower sense in which the term is there employed; but neither the rock caverns and temples of Egypt and India,

[1] Land in the neighbourhood of London, which, as grass land, has been let at from three to five guineas per acre, and the market value of which as such would not be more than from L.100 to L.170 per acre, rises gradually in selling value as the town grows out towards it, until it becomes building land, when its price is counted by thousands of pounds per acre, and that before a turf is turned.

[2] Even a wider view of the duties of property in land applied to the increment of towns may be taken and maintained. Having reference to the source of the increased value which the application of land to building purposes obtains for it, the disposal of the mortal remains of the human beings concentrated upon it by such application, should be provided out of the benefited estates—not by leaving it as a rate to be thrown upon the inhabitants, but by an appropriation of a sufficient part of the site, or an equivalent in money to buy a suitably removed site, to receive the remains of all the inhabitants which the building land may be capable of receiving when, in the course of nature, they must be removed to resting-places for the dead.

Supplement.

nor the mounds of sun-dried bricks on either side of the Tigris, nor the addenda to our knowledge of Greek monumental antiquity supplied by the industry of Mr Penrose at Athens, and of Sir Charles Fellows in Lycia, nor the curious labours of Mrs Hamilton Gray and Mr Dennis in the mines of Etrurian antiquity, nor, indeed, the discoveries of Mr Stephens in Yucatan, add anything really available to the improvement of our knowledge of the constructive arts applicable to works of architecture, or to the design and decoration of such works.

But it may be of interest, nevertheless, to add to the statements contained and opinions advanced in the foregoing treatise as to the habitations of the earlier races of men within the historic period, the following observations of the distinguished labourer in the fields of Assyrian antiquity, to whose intelligence and activity the greatest discoveries above referred to are mainly due, and to inquire into the bearings of the recent discoveries upon the archæology of architecture. Mr Layard writes, in chap. xiii. of his *Popular Account of Nineveh*, page 341—"The earliest habitations, constructed when little progress had been made in the art of building, were probably but one story in height. In this respect the dwelling of the ruler scarcely differed from the meanest hut." And at page 348 of the same work, the author continues the same subject by the remark that "we have no means of ascertaining the nature of the private dwellings of the Assyrians, nor of learning any particulars concerning their internal economy and arrangement. No such houses have been preserved either in Assyria Proper or Babylonia, their complete disappearance being attributable to the perishable materials of which they were constructed; for although the palace-temples were of such extraordinary magnificence, the bulk of the people appear to have lodged, as in Egypt, and indeed in Greece and Rome, in very small and miserable dwellings, which, when once abandoned, soon fell to dust, leaving no trace behind." And having reference to the "palace-temples" laid open by himself in Assyria and Babylonia, Mr Layard remarks, in continuation of the paragraph first above quoted—"It soon became necessary, however, that the temples of the gods and the palaces of the kings, depositories at the same time of the national records, should be rendered more conspicuous than the humble edifices by which they were surrounded. The nature of the country also required that the castle, the place of refuge in times of danger, or the permanent residence of the garrison, should be raised above the city, so as to afford the best means of resistance to an enemy. As there were no natural eminences in the country, the inhabitants were compelled to construct artificial mounds. Hence the origin of those vast solid structures which have defied the hand of time, and, with their grass-covered summits and furrowed sides, rise like natural hills in the Assyrian plains." In further continuation of this part of the subject, the author writes at page 345 of the same work—"The mode of roofing the palaces and lighting the chambers, many of which were in the very centre of the building, with no other inlet for light but the door, is one of the most difficult questions in Assyrian architecture. I am inclined on the whole," Mr Layard writes, "to concur with Mr Fergusson [in his work entitled *The Palaces of Nineveh and Persepolis Restored*] in thinking that light was admitted through galleries or open rows of low pilasters above the alabaster slabs, and that wooden columns were sometimes used to support the roof in the larger halls. It is, however, remarkable that no remains whatever of columns have been discovered, nor are there any traces of them. Unless they were employed, the chambers exceeding a certain width must have been left open to the sky. There is no proof whatever of the rooms having been vaulted, although the Assyrians were well acquainted with the principle of the arch." And having regard to this last-quoted expression, it is necessary to extract the passage which appears to supply the evidence upon which the author may be supposed to rely in using it. This is found at page 266 of the same summary of his earlier but really less informing book, *Nineveh and its Remains*, in the following words:—"It only remains for me to mention a singular discovery on the eastern face of the mound [under one of the explored palaces or temples at Nineveh], near its northern extremity. A trench having been opened from the outer slope, the workmen came upon a small vaulted chamber, about ten feet high and the same in width, fifteen feet below the level of the mound, and in the centre of a wall of sun-dried bricks, nearly fifty feet thick. The arch was built of baked bricks. The chamber was filled with rubbish, the greater part of which was a kind of slag, and the bricks forming the vault and walls were almost vitrified, evidently from exposure to very intense heat. The chamber had thus the appearance of a large furnace for making glass or fusing metal. I am unable to account for its use," Mr Layard continues, "as there was no access to it, as far as I could ascertain, from any side."

Almost every explorer among remains of ancient times, in countries which possess works of high antiquity, but in which works the arch is not found to take its place in the structure, has referred to some example or other which has seemed to him to show that the properties of the arch were known to the builders, or to the people of the nation by whom the works were produced. Reports of examples of vaulted structure, found under circumstances which, like those last above quoted from Mr Layard, seem to assume the high antiquity of the work, have been received from time to time, with assurances derived therefrom that the properties of the arch were known to the people of the place at the time referred to;[1] but notwithstanding such reports, and the evidence adduced, be it real or fancied, the world will continue to deny that either Greeks or Egyptians, Hindoos or Assyrians, were "well acquainted with the principle of the arch," acquaintance with the principle being assumed to include a knowledge of the properties,—when they built, as we know from their grandest existing works they did build, without any exhibition of that acquaintance and that knowledge in their practice, under circumstances in which the arch would have been most certainly applied had its properties been known to the builders. There can indeed be no answer given to the assertion that "the Assyrians were well acquainted with the principle of the arch," more conclusively against it, than the statement by which it is preceded, that "there is no proof whatever of the rooms having been vaulted;" the circumstances of the case having been such, it would appear from the context and the illustrations, as admitted of vaulting. It is possible that a semi-civilized nation may have reached the wedge without attaining to the application of the properties of the inclined plane in a screw, or may have learnt to make the explosive compound known to us as gunpowder, and even to use it for blasting rocks, without attaining to the art of gunnery; but it seems unlikely that the more advanced nations of antiquity, who are not found to have employed the arch in the construction of works in which it would have been to them invaluable, could have been practically acquainted with its properties.

[1] Mrs Hamilton Gray must be excepted from the class of explorers referred to. With the good sense and clearness of perception that distinguishes most of her remarks on the many interesting matters which came under her observation among the remains of the old Etrurian cities, she observes with reference to the arch-shaped structure, known as the tomb of Regulini Galassi at Cæse or Agylla, "I call it a sort of arch, because it would seem to have been constructed before the regular arch was known, or its principles conceived." (*The Sepulchres of Etruria in* 1839, by Mrs Hamilton Gray, page 332.) See illustration on next page, fig. 1.

Most of the misleading examples which have been adduced to show that the properties of the arch were known to the earlier nations of the East, and in Egypt and Greece, have not exhibited even the constructive arrangement of the materials which is essential to an embodiment of the principle of the arch in vertical constructions. An aperture left in a wall to serve the purpose of a door or a window is required to be of limited height,—it is not to be permitted, indeed, to break the continuity of the wall throughout its whole height,—and it must, therefore, be stopped by a covering as a lintel in some efficient manner so that the wall may be carried on over it. The opening being too wide for a stone beam as a lintel to bear over, or a stone not being at hand of length and strength sufficient for the purpose, the courses are made to jut over the sides or jambs of the opening one above another by little and little until the gathering or corbelling over, as it is technically termed, has narrowed the space to be covered so much that the next course above completes the covering. The jutting ends of the stones will overhang, and this being thought unsightly, or found inconvenient, their lower angles are cut away, and the result is the outline in appearance of a pointed arch (See fig. 1), whence probably—as first suggested, it is believed, in the preceding treatise (v. *ante*, p. 446, 2d col.)—the form which was the germ of the pointed style. But the familiar form which at once induces the idea of an arch has misled many an untechnical observer into a belief that he has detected an arch where none has existed. It must be conceded, nevertheless, that the diagrams exhibited by Mr Layard in *Nineveh and its Remains*, his earlier work (published in 1849), and in the *Discoveries in the Ruins of Nineveh and Babylon, the result of a Second Expedition*, first published in the current year, 1853, and showing what are believed to be works of high antiquity, do present all the appearance of arch-built vaults.—See figs. 2, 3, and 4. Moreover, some of the sculptures removed by Mr Layard from his excavations among the Assyrian mounds of ruined palaces or temples, and now in the British Museum, present the appearances of door or gate ways in, or rather upon (for the sculptures referred to are in low relief only), city walls and the walls of buildings, having curved heads, as if they were arched over; but it is to be remarked that although there are frequent indications by lines on the same sculptured blocks, and in the same walls, of the joints of the horizontally-coursed masonry, there are no such lines, radiating or otherwise, above the bowed lines which would seem to present the form of arched heads to openings in the walls as doors or gates, to indicate joints in the masonry, and thereby to exhibit the structure of an arch.

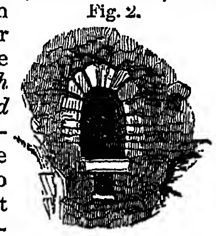

Fig. 3.

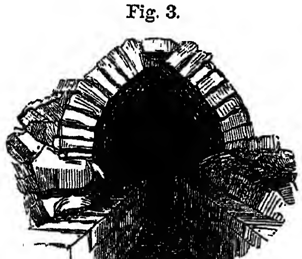

Fig. 4.

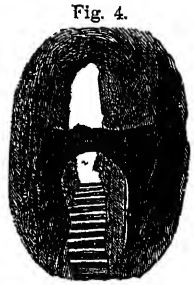


Reverting to the statement above quoted from the *Popular Account of Nineveh*, to the effect that no remains whatever of columns had been discovered, it is necessary to add the fuller paragraph from *Nineveh and its Remains*, from which it appears that it is not columns alone that are wanting in the Assyrian remains of the accustomed architectural display. Having described the wonderful works in sculpture which the mounds afforded, Mr Layard asks, at page 267 in vol. ii., "Were these magnificent mansions palaces or temples?" and observes, as in reply, and to show the absence of means of answering certainly, "Of the exterior architecture of these edifices no trace remains. I examined as carefully as I was able the sides of the great mound at Nimroud and of other ruins in Assyria, but there were no fragments of sculptured blocks, cornices, or other architectural ornaments to afford any clue to the nature of the façade." And so strikingly devoid is Assyria in its ancient remains of all such matters, that Mr Layard again, in his more recent work (Layard's *Discoveries in the Ruins of Nineveh and Babylon: being the result of a Second Expedition*. Lond. 1853), writes, at page 530, "We find no remains of columns at Babylon, as none have been found at Nineveh."

But Mr Layard has furnished the sufficient and conclusive reasons why columns and their accessories do not appear among the Assyrian remains. "The architecture of a people must naturally depend upon the materials afforded by the country, and upon the object of their buildings. The descriptions already given in the course of this work," *Popular Account*, "of the ruined edifices of ancient Assyria, are sufficient to show that they differed in many respects from those of any other nation with which we are acquainted. Had the Assyrians, so fertile in invention, so skilful in the arts, and so ambitious of great works, dwelt in a country as rich in stone as Egypt or India, it can scarcely be doubted that they would have equalled if not excelled the inhabitants of these countries in the magnitude of their pyramids, and in the magnificence of their rock temples and palaces. But their principal settlements were in the alluvial plains watered by the Tigris and Euphrates. On the banks of those great rivers, which spread fertility through the lands, and afford the means of easy and expeditious intercourse between distant provinces, they founded their first cities. On all sides they had vast plains unbroken by a single eminence until they approached the foot of the Armenian hills." (Pp. 340 and 341.)

Hence it is that the Assyrian ruins present no remains of columns and entablatures—the Assyrians had no stone but the tender and friable alabaster, which is capable of becoming almost plastic in the hands and for the purposes of the sculptor, as the Assyrian sculptures abundantly show; but which is wholly unfit for the purposes of the architect in his normal character of a constructor. Wanting stone out of which to form columns and architraves, the difficult question presents itself, as to the mode employed "of roofing the palaces and lighting the chambers." Mr Layard's opinion on this point, coinciding with that of Mr Fergusson, is given in the extract already quoted on the preceding page. "A mass of charred wood and charcoal," and "part of a beam in good preservation, apparently of mulberry wood, found near the southern entrance of the great hall" (*Popular Account*, p. 265), yield almost conclusive evidence that timber had been employed in the buildings for some purpose or other; and a woodcut at p. 252 of Mr Layard's more recent book already quoted, which contains the result of a second expedition, being further discoveries in the same countries, of a view of the interior of a modern house in the Sinjar, shows very clearly

how timber may have been employed in the formation and support of the roofs of the palaces or palace-temples of the ancient Assyrians, while the heavy sun-dried brick walls and piers may still form the outer lateral inclosure and supports of the building; that is to say, the flat roofs may have been, and probably were, structurally of timber, upborne by the outer walls of brick burnt or unburnt, aided intermediately by posts of timber and covered with bitumen.[1] Stability was given to the structure by the masses of sun-dried brick, and shelter for the inhabitants from the weather by the timbered flat coated with bitumen. But buildings so composed were both fragile and combustible; and fire taking the roofs, the walls and pillars fell into the heaps which Assyria and Babylonia have presented to the modern traveller.

It is most probable, too, that the Assyrian palace-temples, or whatever else they may be designated, were, for the purposes of light and air, hypæthral, and that the several halls presented each the arrangement, as it regards the admission of light and air, exemplified by the peristyled atrium of a Roman mansion, as shown by the Pompeian remains at the present day, and used as an illustration in Plate LXI. accompanying the preceding treatise.

Mr Fergusson, in the work referred to by Mr Layard, and in the frontispiece to Mr Layard's *Discoveries in the Ruins of Nineveh and Babylon, being the result of a Second Expedition*, and hereinbefore quoted, imagines combinations of timber for which the patent documents afford no sufficient authority, and which require greater skill in carpentry than the Assyrians and Babylonians are likely to have possessed. The wooden coffins of the Egyptians of the same time show us very plainly the state of the joiner's art among them; and a technically informed eye can readily determine the advance a people may have made in carpentry by the putting together of even a coffin, though that is a piece of joiner's work. It does not appear from any of Mr Layard's statements, as records of fact, that the beam found in the S.W. palace of Nineveh, or any other piece of timber discovered among the ancient remains in the countries which he has so well described, exhibited any of the operations of carpentry;—no indent as a mortise, and no projected end to a piece of timber as a tenon. It is true that the sculptured slabs of alabaster were kept in their places "as a kind of panelling to the walls of sun-dried bricks" (*Popular Account*, p. 343), "and held together by iron, copper, or wooden cramps in the form of double dove-tails." The dove-tail joint is found, though in a rude state, certainly, in the Egyptian coffins or mummy cases, of which such large numbers are open to public view in the British Museum; and so is the dowel found, used as a means of connecting boards one with another, by the face or by the edge, in the form of the pin-dowel, so familiarly known as the means by which the head of a cask is put together; and in the form of a tenon-dowel, which the Egyptians employed to attach the cover to the case, wooden pins giving the means of keying them. Pin-dowels are driven so as to set tight against the transverse section of the fibre, whilst a tenon-dowel requires to be held in the mortise by pins passing transversely through them. The coffins or cases of the earliest dates do thus present both mortise and tenon, as between board and board, with the fibres running parallel in each; but they do not present the mortise and tenon joints of carpentry, whereby timber may be framed; for which purpose the tenon must be formed on the end of one piece, of the substance of the piece, and be inserted at right angles for the most part into a mortise, being an indent of corresponding size and form in the substance of another piece; that is to say, the oldest coffins or cases do not exhibit framing, in the proper sense of the term, as a means of connecting timbers one with another; nor is the true mortise and tenon joint found in the large collection referred to, until the Greek or Ptolemaic period, when, and in the Roman period, the Egyptian coffins or mummy cases are found to be framed together as the rails are framed into the legs of a common table. Whilst existing remains of early Egyptian joiner's work show that the early Egyptians used the dove-tail and the dowel, and there is nothing to show that they knew the proper framing joint whereby alone timber may be efficiently put together to form a framed structure, we find no evidence upon which we can conclude, or may admit, that the Assyrians and the Babylonians were in advance of the Egyptians in that respect. We must therefore conclude that the timber structures suggested by Mr Fergusson, and adopted by Mr Layard in the frontispiece design of his books, which could not have been put together as safe structures without a system of framing and bracing beyond the skill in practice of the early Egyptians, could not have been carried out by their contemporaries in Mesopotamia. Nor does it appear, from anything discovered, that either Egyptians, Assyrians, or Babylonians had the means of making up for want of skill in carpentry, as the modern European and particularly English architects do make up for such want, by a profuse use of nails and screws, and of rods, bars, straps, and bolts of iron. The modern Yezidi houses in the Sinjar Mountains, above referred to as presenting local instances of timber structure, exhibit the timber in such manner as to show that even the modern Assyrian puts timber together as the ancient Egyptians did stone, and not by means of carpentry—relying upon mass, and the gravity that accompanies mass, even with the lighter body; but neither the one nor the other got by such means—whether with stone, brick, or timber—beyond one story high.

Our denial in the preceding treatise that the properties of the arch were known well enough at least to be appreciated by the more ancient nations of the East, including those of Egypt and Greece, until the arch had first become of general application in Italy, remains thus unimpeached by the recent discoveries in the valleys and plains of the Tigris and Euphrates; whilst in like manner our impeachment of the dendroid theory of the origin of those combinations of ancient works to which the designation architectural has been specially applied, receives negative confirmation from the results of Mr Layard's admirable labours.

To the foregoing observations it is to be added, that, although we have become possessed of no valuable addition to our previous stock of architectonic materials by the explorations in the Mesopotamian fields, the workings have brought to light much interesting documentary evidence, to the effect that the Greeks found the germ of their beautiful ornament, known to us as the honey-suckle, and so commonly used by them in the enrichment of their Ionic style, in Assyria. Mr Layard gives in the *Popular Account* (pp. 44, 45) the following interesting statement in connection with this subject:—"Adjoining this slab was a second, cut so as to form a corner, sculptured with an elegant device, in which curved branches, springing from a kind of scroll work, terminated in flowers of graceful form.........The flowers were

[1] "On the following day we passed the bitumen pits, or 'Kiyara,' as they are called by the Arabs. They cover a considerable extent of ground; the bitumen bubbling up in springs from crevices in the earth and forming small ponds. The Jebours and other tribes encamping near the place, carry the bitumen for sale to Mosul and other parts of the Paschalic. It is extensively used for building purposes, for coating the boats on the river, &c. . . . . Before leaving the pits, the Arabs, as is their habit, set fire to the bitumen." (*Popular Account*, c. xi. pp. 269, 270.)

Supplement.

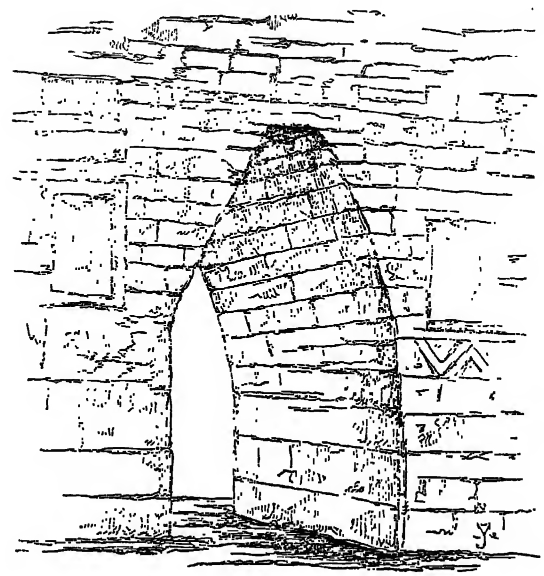
formed by seven petals springing from two tendrils, or a double scroll; thus, in all its details, resembling that tasteful ornament of Ionic architecture known as the honey-suckle. The alternation of this flower with an object resembling a tulip in the embroideries on the garments of the two winged figures, establishes beyond a doubt the origin of one of the most favourite and elegant embellishments of Greek art." Having regard to the sculptures referred to by Mr Layard, and to other evidence to the same effect, Mr Fergusson goes so far as to express an opinion—at page 340 of his ingenious speculations, under the title of *The Palaces of Persepolis and Nineveh Restored*—that "it is now impossible to doubt that *all that is Ionic in the arts of Greece is derived from the valleys of the Tigris and Euphrates.* But perhaps this opinion should receive the same qualification that would certainly be required for a declaration to the effect that all that is excellent in modern carpentry is derived from the Persian and Assyrian palaces, as exhibited in the preface to Mr Layard's book which contains the results of his second expedition; being a fanciful display of lofty and many-storied buildings, for the structure and disposition of the outer features of which Mr Layard's books contain no evidence.

It was not long before the exhumation by Mr Layard in Central Asia, of the wonderful remains of fine art in monstrous combinations of brute and human forms, entombed in earthen mounds, that Mr J. L. Stephens, when engaged on a mission from his government—that of the United States of North America—to some of the mutable states of Central America, heard of and tracked out in the forests of Yucatan[1] the remains of a bygone time exhibited in sculptural and architectural monuments of a coarse character, and revolting as regards the representations of human and bestial forms in sculpture, but not more revolting than the more elegantly designed and beautifully wrought works of the Central Asians; whilst the architectural remains afford a strange counterpart to those which Mr Layard describes, as he imagines them to have existed in and about the valleys of the Tigris and Euphrates. Huge mounds, constructed pyramid-wise and of stone, form in Yucatan the bases of the temples and shrines upon which some former inhabitants practised the horrid rites by which they thought the Almighty was to be worshipped; as in Assyria, there were mounds of the material the country afforded upon which the temples and shrines of an equally unholy worship was performed by the more graceful but most abominable sovereigns, subjects, and slaves of the Eastern tyrannies.

The graphic illustrations of Mr Stephens's records of his discoveries are by an English artist whose study had been especially architecture, and whose drawings may be taken, therefore, with more confidence to represent truly the forms and the disposition of the materials which the architectural remains of Yucatan present, than may be prudently yielded to the drawings of artists not so prepared. Mr Catherwood, the artist referred to, is known to have spent some of his earlier years in Egypt and the East, and he was thereby familiar with the ancient remains of those parts of the world; but it is not to be imagined therefore, that he drew upon his memory for the forms and dispositions of the materials of the American monuments. It is certain, however, that if the drawings Mr Catherwood has published of the architectural remains discovered in Yucatan, had been presented to the world as of remains found in hitherto unexplored parts of Nubia, or as existing in any part of Mesopotamia, or in the countries lying between Persia and the Tigris, they would have been taken to be prototypes of the more finished and more magnificent monuments so familiar to the world as the remains of the higher civilization of Egypt and the East.

Among the objects represented in Mr Catherwood's *Views of Ancient Monuments in Central America, Chiapas, and Yucatan*, are several examples of vaults having the arc form but not being arched vaults; that is to say, of vaults presenting the appearance internally, or upon the soffit, of arches, but formed by the gathering over of horizontally-coursed masonry, with the inner and lower angles worked away—or cleaned off, as it is technically expressed—to the appearance on the inside which an arched vault would present. See fig. 5.

Fig 5.



The circumstance that the arch form presented in the American monuments is produced by the gathering over of horizontally-ranged masonry, and not by means of arch structure, would seem to show clearly that if their builders ever had intercourse with the Old World, it was before the properties of the arch were known and practised in it. These remains show an advance on the Pelasgic and Celtic monuments of the cis-atlantic world, and take the general character of the stone works of Egypt and India; but like those works they exhibit the vaulted form by gathering over and not by arching.

Mr Catherwood states, at page 9 of the Introduction to the *Views*, that he and Mr Stephens concur in the opinion of Mr Prescott, the eminent author of the *History of the Conquest of Mexico*,—"that though the coincidences are sufficiently strong to authorize a belief that the civilization of Anahuac (Ancient Mexico) was in some degree influenced by Eastern Asia; yet the discrepancies are so great as to carry back the communication to a very remote period, so remote, that this foreign influence has been too feeble to interfere materially with the growth of what may be regarded, in its essential features, as a peculiar and indigenous civilization;" and this opinion the monuments, as presented by Mr Catherwood, would seem fully to justify. But Mr Catherwood adds to this, as the ground, it would appear, for coinciding with Mr Prescott's opinion, that the results arrived at by Mr Stephens and himself "are briefly, that they (the American monuments) are not of immemorial antiquity, the work of unknown men; but that, as we now see them, they

[1] Lord Kingsborough's great work on the *Antiquities of Mexico* contains, in some of the later volumes, representations of monuments which would almost appear to be the same as some of those subsequently explored by Mr Stephens.

Supplement.

were occupied and probably erected by the Indian tribes in possession of the country at the time of the Spanish conquest, that they are the production of an indigenous school of art, adapted to the natural circumstances of the country, and to the civil and religious polity then prevailing; and that they present but very slight and accidental analogies with the works of any people or country in the old world." These results do not appear to accord with, but rather to controvert, the opinion expressed by Mr Prescott as above quoted; but neither the historian nor the explorer and his illustrator had at the time they respectively wrote the advantage of comparing the arrangements made alike by the ancient Assyrians and by the ancient Americans with one another, in respect of artificial high places upon which they respectively erected their temples, exhibited their monstrous idols, and performed their horrid rites, or they must have recognised the necessity, almost, of such results of a barbarian civilization having had a common origin. And having regard to this point, we refer to the paragraph in the preceding treatise (p. 438, 2d col.), where, by the aid of Humboldt, and without the light afforded by the discoveries of Layard in the East, and Stephens in the West, we had arrived at the conclusion to which a consideration of the evidence afforded by their labour has again brought us.

The researches of Sir Charles Fellows in Lycia have led to the discovery of some interesting monuments possessing architectural features which bear the Grecian impress; but they present nothing greatly valued by the practical architect of which he was not already in possession.

Mr Penrose has found, upon a more minute examination of the Parthenon than had perhaps been at any time before made of it, that its floor is slightly in rounding, to use the technical phrase, and that the entablatures are not in perfectly straight lines, or that they only appear to be straight and are not so; the supposed tendency of the eye to see crooked having been corrected in this particular case by the architect through the agency of the mason. If the noble ruin had not been exposed through long ages to quakings of the earth under it, and had not certainly been shaken by the explosion of a bomb shell within it, even the most minute aberrations from the line and the level in a work so carefully executed as the Parthenon was, might not be unreasonably attributed to design; and if the aberrations found to exist were intended, there may be reason to suppose that entasis was applied to the leading horizontal lines of the structure as a whole, as it certainly was to the outline of the columns, to convey to the eye the desired effect of truly straight lines. Mr Penrose has had the advantage of examining the remains of the Propylæum of the Acropolis without restraint, and he justifies the note by the late Mr W. Kinnaird in correction of Stewart and Revett, referred to in a note at page 462 *ante*. He points out also several other matters of interest to the student in the disposition of the parts of that structure. For some further details connected with this subject see ATHENS.

Mr John Pennethorne, who appears to have been the first to remark and call attention to the peculiarities in the Parthenon, which formed the main subject of Mr Penrose's examinations there, has subjected the forms and proportions of that monument to mathematical investigation; and Mr D. R. Hay has shown how the forms and proportions of the same structure may be educed from his ingenious system of geometric developments.[1]

Mere verbal reference to the many published delineations of existing works of date subsequent to the classical period, which is all that could be made in this place, would not convey any valuable information to the reader; but, indeed, there was very little to add to the amount of useful, and this is not the place for merely curious, information concerning them. The manner, of which the Constantinian Basilica is the type, so far as regards form and the disposition of the structure, is in some degree indicated by the front of Pisa Cathedral; though truly the style of design is almost as various as the examples. The buildings—for the most part churches—of the Constantinian period are commonly masked at the present time by an Italian exterior of the *cinquecento* style of design, whilst the more properly middle-age buildings are consistent throughout; but, as before remarked, the variety as to detail is great, though the leading characteristics continue much the same to and even through the true Gothic period of the northern nations, and until the introduction of the pointed arch. The terms Romanesque, Byzantine, and Lombardic, are now commonly, but uncertainly applied to the works referred to as antecedent to the Norman period; but the term Gothic is, nevertheless, generally applicable even to the Italian works of the middle ages, and most truly so to everything produced north of the Alps throughout the middle ages, and down to the time when the pointed arch gave a new character to construction as well as a new style.

Plate LXX.

The greatest of the Moorish remains in Granada have been made better known by the labours of the late able illustrator Mr Jules Goury, followed up by Mr Owen Jones in his well-sustained joint character of architectural draftsman and artist, but the more pretending ecclesiastical structures of Spain which purport to be in the pointed style have yet to receive similar attention. Cicognara continues to be the only trustworthy illustrator of that mine of beauty in architectural design, Venice; but his fine work is not easily obtained, and it is costly. Personal acquaintance with the works in the pointed style of Northern France, Flanders, and the Rhine, has led to a higher appreciation of the effect produced by magnitude and extent as exhibited in the greater churches, and to admiration of the choirs and chancels of some of them, and of the Belgian churches especially. Illustrations are to be found sufficiently indicative of the general characteristics of the manner of these works, but nothing short of personal knowledge can convey a true impression of their effect, while the peculiarities of construction can only be guessed at from merely pictorial illustrations.

At home correct delineations from actual admeasurement of our great works in the pointed style are more frequent than in any country abroad; for it continues to be true that the style is nowhere so well understood, so highly appreciated, or so much abused in applying it, as it is in the British Islands.

The old architectural wealth of Scotland has been recently made known beyond her own limits by the labours of Mr R. W. Billings, who being, like Mr Owen Jones, an architect as well as an artist, has known how to present the subjects so as to exhibit much of the structural character of the work in every case, as well as to give pictorial effect to his illustrations.

SECTION III.

No instance of sufficient mark and interest to be spoken of here has occurred within our knowledge, of the application, in modern practice and to modern purposes, of the mode and

[1] While the mathematician and the geometer have made the forms and proportions of the classical models of architecture their study, to discover and to determine the principles upon which they were established, so that by their application in modern practice, the excellent qualities of the antique examples might be obtained, the world of British architects have occupied themselves and amused the public with discussions upon some indications of plastering and painting which have been detected upon the surfaces of some of the architectural and sculptural remains of antiquity. The subject of discussion is designated Polychromy, and the taste which deems such trifling a matter of serious interest is distinguished by the term Æsthetic.

Supplement.

style of composition peculiar to the structures, as they remain to us, of ancient Egypt—the earliest in date as in manner of any existing structures of high antiquity which display taste and refinement in their disposition and details—so as to make them worthy of study for any advantage derivable from such study; nor do instances present themselves of noticeable endeavours to apply the form presented by any ancient remains in Persia or in India; and we shall find, upon reference, that the now recent researches on this side of the last-named countries, have eliminated nothing likely to be of more interest and utility in practical architecture than the known remains of Egypt, Persia, and India, and already presented for the information of the inquirer and the study of the practitioner. The great western continent had already yielded up to the observation of the rest of the world many monuments interesting to the archæologist, but presenting nothing to distinguish them as works of taste or of mechanical skill, in which they are not far excelled by many remains of antiquity in the middle countries of the Old World.

The instances which present themselves on all sides of endeavours to adapt the columnar ordinances derived from the noble structures of ancient Greece are numerous; but it is to be added, that so far as regards the most noble and the most distinguished of the Grecian styles, every instance must be regarded as a failure. Even the Walhalla in Bavaria, which is understood to be professedly a reproduction, as to exterior form and distribution, of the Parthenon, is without the inner portico at one of its fronts—the opisthodomus is wanting. In what manner, or with what effect, the work is executed, the present writer has no personal knowledge; but at best the Walhalla is an exceptional case, and cannot be taken to be an adaptation of the Greek style to a modern purpose, but a copy, and an imperfect one, of a Greek temple. The interior of the Walhalla cannot be accepted as an embodiment of either Greek taste or structural propriety, whilst the rapid constructed approach from a low level to the elevated site of the building cannot fail to be injurious to the effect of its exterior, if it be only by taking the roof out of the view; but the graduated stylobate must also be intercepted and thereby lost to the view throughout much of the circuit.

The Grecian Ionic ordinance may be thought to have yielded in some degree to the requirements of modern uses; but having less of dignity to lose than the more purely Greek style—the Doric—and being exhibited in no ancient remains in such effective combinations as the Doric, modern compositions of which the Ionic ordinance forms the basis have the advantage over those which exhibit the Doric features of being tried by a less severe test. Nevertheless, the results, in the more prominent instances which London presents, of the application of the Grecian Ionic in modern structures do not tend to encourage the endeavour to mould this more plastic ordinance to modern purposes.

In compositions of less pretence, nearer approach may have been made to success in the application of the Greek Ionic ordinance. But the great defect of one in particular of the Athenian examples—that of the portico of Minerva Polias—of an inordinately wide intercolumination, whereby structural weakness is induced, is too commonly taken as an authority for such a disposition of the columns as that example presents, to the great detriment of most reproductions in modern instances of the Greek Ionic.

Corinthian, as an ordinance, is more Roman than Greek, and is much more plastic than the more purely Grecian ordinances; and being more plastic, it has been applied in modern practice and to modern purposes more extensively, and with greater success, than the less exacting, as it regards enrichment, but more exacting as it regards the circumstances under which they may be applied in practice, Doric and Ionic of the Greeks. It may be that the Corinthian column, being a more finished and acceptable object in itself than either the Doric or the Ionic column of whatever style, the eye exacts less, in respect of accessories and concomitants, from the Corinthian column than it does from the Doric and Ionic, which as columns are nothing; that is to say, they are unmeaning, and to some extent ungainly, objects, unless it be in appropriate composition, and with all the requisite accessories to complete the respective ordinances; whilst the Corinthian column, with its richly foliated and otherwise enriched capital, coped with a moulded abacus, and bound below by a moulded hypotrachelium, its fluted shaft and its moulded and enriched base, is itself an object to satisfy the eye, while the mind inquires less urgently for what purpose it is intended, and how it is to be disposed in composition.

However this may be, there can be no doubt, that whether the peculiar form in which the Corinthian ordinance presents itself be Greek or Roman—that is to say, whether the characteristics and details be those of the Greek example, or of a Roman example, to which the designation Corinthian is conventionally applied, or to that form of the foliated style which is by the Italo-Vitruvian school distinguished as the Composite order—it can be applied, whether in its full proportions, or shorn of some of its parts and details, with a success that has not attended the application of Doric and Ionic, in whatever guise.

But even the classical Corinthian ordinance is seldom found applied in modern works either at home or abroad, without sacrifice being made, in a greater or less degree, of the purposes of the work to the demands of the classical exemplar employed, or the more common sacrifice of the proportions found in the exemplar to the necessity of the case. Now the proportions found in the purer columnar architecture of Greece and Rome, of whatever style, are necessary results of the materials employed and of the mode of applying the materials in composition. The exemplars are all in stone of some kind or other, and the proportions and dispositions are such as the use of stone in legitimate structure of the sort applied would impose. Columns are placed as far apart as stone of the kind used in the case will bear over with certain safety in an architrave or lintel from column to column; such due proportion being observed between the horizontally disposed stone beam bearing over, and the vertically disposed stone column that has to support the superstructure, as the weight may require. Hence intercolumniation, or the space to be borne over, is not a matter of fancy, but of structural necessity; and the applicability of a classical columnar ordinance is structurally limited by the quality and character of the stone employed. Stone beams cannot be pieced out in length to bear over a void by any legitimate, or, what is commonly but expressively termed *workmanlike* manner; and arched structure is inadmissible in a pure columnar composition, as arches of whatever form require to be buttressed; and the essence of a columnar ordinance as a structure is in the weights being applied to act upon the column in that direction only in which the column is qualified to bear pressure; that is to say, vertically, or in the direction of its vertical axis. Marble will bear both transverse strain and vertical pressure better than freestone, and granite better than marble; and hence it is that the several parts of columnar ordinances in the works of the Greeks are more massive in their proportions when freestone is used, and lighter in the examples in which marble is employed; and the same relation will be found to exist between heavy and light proportions in the Egyptian temples. It is not according to their respective dates, but according to the material employed in the structure, that the proportions of the parts to each other are heavier or lighter,—the structure is more condensed or more drawn out as sandstone or porphyry is the constituent material of the building. It is the same with the better

Supplement.

works of the Roman period; that is to say, in the composition of the columnar ordinances of their sacred structures; and the Romans indulged in the use of almost every kind of stone available for the purpose in the columnar ordinances applied to their temples.

Thus out of truth in structure, having reference to the material employed, grew the forms and proportions found in the classical exemplars of columnar architecture, stone being the material of the structures, and the capability of the stone to bear and to bear over giving the limit to the columns, and to the parts required to bear over, and thereby prescribing the proportions of the parts to each other, and to the spaces between the bearing parts. To falsehood in structure are attributable the failures to reproduce in modern compositions the admirable effects found in the columnar ordinances of the Greeks and Romans in which truth prevailed. Proportions permitted by marble are repeated in tender freestone, and this failing, foreign substances and unworkmanlike tricks of handicraft are applied to cheat the sense; but the eye refuses to be deceived, even if the structure endure. There may be sufficient strength in reality, for the effective material employed may be timber or iron, or other substances capable of yielding the required result in strength with far slighter proportions than stone of any kind truthfully applied will permit; but a tutored eye will detect the weakness in effect; and not unfrequently the trick is exposed to the common observer by some failure in the means adopted in the case.

The entablature of the central bay of the lower pseudo-prostyle of the west front of St Paul's in London, reaching from column to column, over a disproportionately wide intercolumniation, exhibits a well-marked instance of the failure of the false structure whereby it was endeavoured to cheat the eye. The architrave is in three stones; that is to say, the architrave stones bearing on the adjacent columns are pieced out by a third stone, which having no true structural connection with them, the middle length has torn itself away from its illegitimate attachments, and the stone above it in the frieze is broken across; or it may be, indeed, that the suspended block in the architrave was hung up to the frieze course; but be that as it may, there it is a striking example of undue proportions exhibiting themselves in the failure of the means by which they were obtained.

Structural untruth is not to be justified by authority. Neither Sir Christopher Wren, nor the Athenian exemplars of Doric and Ionic in the Propylæum, and in the Minerva Polias, with their irregular and inordinately wide intercolumniation, can persuade even the untutored eye to accept weakness for strength, or what is false for truth. Probably no eye ever regarded the middle bay of the Propylæum with satisfaction after having looked upon the Parthenon; and certainly none could turn with pleasure from the well and truly proportioned disposition of the columns of the Erechtheum prostyle to the straggling columns of the adjacent portico of Minerva Polias.

This doctrine may be supposed to preclude the use as models of the classical exemplars in architecture of the most tasteful nations of antiquity, unless reproductions be made of the materials as well as in the manner of the antique exemplar. But this no more follows than that a man who cannot afford to possess himself of sculptures in marble shall not accept casts; the architect is not precluded from applying the truth and beauty of form and proportion found in the classical examples in consistent composition, in any fitting material proper to the purpose of the work. Mr Welby Pugin did not hesitate to employ brick-work in the face as well as in the heart of the work, in building the Romish church known as St George's, Southwark, though the great exemplars of the style he employed are of stone; but he modified the proportions to the material, and produced a truthful and in many respects an admirable work.

To do this or that, however, merely because this or that is found in canonized examples of a period or of periods in which works of high merit and great beauty were produced, is not less preposterous than it is to endeavour to apply the classical columnar ordinance, and to pay no regard, in doing so, to the principles upon which their beauties are founded. And the same observation applies alike to every style of architectural composition.

Out of truth in structure, and that structure of a very inartificial sort, grew the beautiful forms of the admirable proportions found in the works of the Greeks, and out of truth in structure, with the strictest regard to the necessities of the composition and to the materials employed—and that structure of a sort as full of artifice as the artifice employed is of truth and simplicity—grew the classical works vulgarly called Gothic, but more characteristically designated Pointed, from the form of the arch which is the basis of the style. But the classical columnar degenerated into the Italian of the *cinquecento*, in which columns and their accessories are constructed as ornaments, and are no part of the structure as such with which they are mixed up, or to which they are affixed; and the classical Pointed fell into desuetude, or was found only in a debased connection with the Italian—picturesque at times, but more commonly grotesque, and never with any claims to decent bearing.

Truly, however, the purposes of modern life are not fully answered by either of the grand and ruling styles—the classical columnar of the Greeks and Romans, and the classical Gothic or Pointed. They both had their birth in those frailties of man which lead him through devotion to superstition, and in structures intended for the worship of the unknown God, the noblest results of both styles were and still are exhibited;[1] and neither the classical columnar, nor the classical pointed bends itself, or allows itself to be bent to secular purposes without loss of both truth and beauty.

Doubtless there is much to admire in many of the productions of the Italian school of architecture, from the *cinquecento* period down to the present time; and many recent works in the pointed style, and some in the mongrel manner that arose out of its debasement in connection with the Italian, exhibit, if not originality, at the least careful copying.[2] Copying, with an affectation of originality, indeed, is carried to such an excess in modern English practice, that mere monstrosities are sought out to be copied. Wearied with building spires upon the towers of churches of such reasonable proportions that they may at once please the eye and be safe as structures, recent practice has set up

---

[1] It is a remarkable fact, indeed, that the greatest excellence in architecture has been obtained in connection with the grossest errors in theology. Witness Egypt, Greece, and Rome.

[2] Mere copying, and the most servile copying, is the ruling vice of the day, and it cannot be denounced in more eloquent language, or in more just terms, than it has been done in the following passage by an eminent person, a distinguished member of his sect in England:—"We have almost canonized defects, and sanctified monstrosities. What was the result of ignorance or unskilfulness, we attribute to some mysterious influence or deep design. A few terms give sanction and authority to any outrageousness in form, anatomy, or position; to stiffness, hardness, meagreness, unexpressiveness—nay, to impossibilities in the present structure of the human frame. Feet twisted round, fingers in wrong order on the hand, heads inverted on their shoulders, distorted features, squinting eyes, grotesque postures, bodies stretched out as if taken from the rack, enormously elongated extremities, grimness of features, fierceness of expression, and an atrocious contradiction to the anatomical structure of man,—where this is displayed,—are not only allowed to pass current, but are published in the transactions of societies, are copied into stained glass, images, and prints, and are called 'mystical,' or 'symbolical,'

Supplement.

in London and its vicinity several offensively acute, and dangerously poised erections, as spires. Monstrous dwarf towers, having the appearance of wind-mills without arms, almost alternate with the feeble spires, and, consistently enough, the natural order is commonly reversed in placing these things; towers are set up in the plain, and spires are erected on the hills.

The works of living men may not be dealt with unless it be to praise them; and thus there are but few recent works in London, or elsewhere, within the personal knowledge of the present writer, which can be referred to in this place in illustration of the practice of the day.

London is indebted to Sir Charles Barry for an admirable example of the better kind of Italian street architecture in the Travellers' Club House, which shows how much of beauty may be obtained by just proportions, tasteful disposition, and unpretending decoration. The north or Pall Mall front would seem to be the result of a study of the Pandolfini Palace at Florence, to which it is fully equal in merit; but the south or Carlton Gardens front, which is in the manner of the Venetian school of design, is really beautiful, and as far excels anything else hitherto produced by the same architect as his works in Pall Mall excel all others in that street of great pretence. The Reform Club House exhibits the general features of the principal front of the Farnese Palace at Rome; but the proportions of the upper story particularly of that great work are not obtained, and the grandeur of the original is not fully attained, whilst the recent work is overpowered by the noble and fitting crowning cornice of the model. These sister buildings, standing side by side, deal hardly with one another, because of the great difference between them in height and magnitude; but each being made complete in elevation by the exhibition of its roof as a part of the composition, not only bears the presence of the other without suffering from it, but, together, they show by contrast the beauty of propriety in the exhibition of a fitly covering roof in contrast with the pavilion parapet so commonly exhibited as a mask to, or rather as an apology for, a roof. The plans of the Travellers' and the Reform Club Houses are also well devised, and are of great merit.

Plate LXVI., fig. 3.

The effect of the Travellers' Club House upon recent productions throughout the country has been great and beneficial, for the style of design which it presents is now often applied with good taste and proper feeling, though few practitioners seem to understand fully how they are to manage the roof so as to do without a parapet; or rather, perhaps, the parapet, in some form or other, has been so long looked upon as an essential, that few know how to do without it. They must have columns, too, upon their fronts, without knowing how to apply them inoffensively, as Vignola applied them in his beautiful Villa Giulia; and as Mr Cockerell has done in his beautiful elevation of the Sun Fire Office, at the corner of Threadneedle Street and Bartholomew Lane in London.

Plate LXVI., fig. 2.

In a small church at East Charlton, near the western boundary of Woolwich, Mr Gwilt has shown how much of good effect as well as useful service may be obtained with great economy in the application of the Italian style of design, in its earlier and simpler form, to ecclesiastical purposes. At Streatham, another suburb of London, there is a church in the Lombardic manner, by Mr Wild, also of plain and simple character, but the manner is not capable of any very agreeable effect.

The Romish church in St George's Field, Southwark, designed by the late Mr Welby Pugin, is, without doubt, the most truthful composition in the pointed style of the time; and out of truth in composition and perfect simplicity has arisen that quiet beauty which is so seldom found in modern compositions affecting that style; but as the tower is not wholly built up, and consequently the spire (as one must have been intended) remains unbuilt, the work is wanting in completeness, and consequently in the effect which, as a whole, it would be likely to produce.

An endeavour, and not unsuccessful, to vary the monotony too commonly prevailing in the streets of London, has been made by Mr T. H. Lewis, in erecting a building on the east side of Leicester Square, for purposes similar to those of the well-known Polytechnic Institution. The Panopticon purports to be studied upon the style of design prevalent in the capital of modern Egypt, presenting to a large extent flat surfaces, or surfaces diversified by slightly profiled proportions. The whole elevation is enriched by coloured materials disposed for pleasing effect, and the effect produced is very striking, and far from unpleasing.

A house has been recently erected in London in the style of design prevalent in the streets of Paris; under a misapprehension, it may be thought, that an arrangement which is found to be pleasingly effective in the narrow streets of that city must necessarily be productive of a similar effect upon the verge of a park.

Much might be said without offence of the extensive works in architecture of novel character, erected for railway stations, and in connection with them; but they are for the most part of so fleeting a character that, judging from the past, most of what exists now in the autumn of 1853, may have fallen down, or have been pulled down, to make way for something else before the autumn of 1854.

In treating of the practice of architecture, the practice of architects must not be wholly passed over.

There are in London two associations, claiming somewhat of a national character, of persons practising in, and in connection with, architecture;—one the Institution of Civil Engineers, and the other the Royal Institute of British Architects.

The Institution of Civil Engineers was founded in 1817, "for facilitating the acquirement of professional knowledge and for promoting mechanical philosophy." This body contains many of the ablest and most ingenious constructors and mechanicians of our country.

The Transactions of the Institution of Civil Engineers are voluminous, and they contain much valuable matter in fulfilment of the declared objects of the institution.

The Institute of British Architects was founded about the year 1835, "for facilitating the acquirement of architectural knowledge, for the promotion of the different branches of science connected with it, and for establishing an uniformity and respectability of practice in the profession." This body numbers among its members most of the artist architects of the day. It has published two half volumes of transactions, in which there are some fine graphic illustrations, and useful practical observations. (W. H—G.)

Supplement.

---

or 'conventional' forms and representations. And this is enough to get things praised and admired, which can barely be tolerated by allowance for the rudeness of their own age. We have seen representations of saints such as we honestly declare we should be sorry to meet in flesh and blood, with the reality of their emblematic sword or club about them, on the highway at evening. And because these were the productions of an *age* eminently Catholic, they are considered as the types of an *art* equally so. But religious art does not look at time, but at nature, which changes not, and at religion, which is equally immutable. To make rude carvings, because the building on which they are placed is Norman, or to make a stiff design because the glass is framed in early English tracery, may be all quite characteristic, but it is not artistic. The object of all art is to speak to the eye, and, through it, to the feelings; and the object of religious art is consequently to excite, through the sight, religious emotions, adequate to the subjects or persons represented."—Cardinal Wiseman's *Essays on Various Subjects*.

GLOSSARY OF NAMES AND TERMS USED IN ARCHITECTURE.[1]

ABACISCUS (diminutive of Abacus, *q. v.*) This term is applied to the chequers or squares of a tessellated pavement.

ABACUS (Gr. αβαξ, a square tile or table). The rectangular and equilateral tablet covering the ovalo of the capital of the Doric column, and on which the superimposed entablature rests, is called the abacus; and from it the similar part (though differently shaped) of all capitals is distinguished by the same term. Abacus means the same thing, but is opposed in application to PLINTH, *q. v.* See also Plate LXII. fig. 1.

ACROTERIUM (Gr. ακρωτηριον, the summit or vertex), a statue or ornament of any kind placed on the apex of a pediment. The term is often incorrectly restricted to the plinth, which forms the podium merely for the acroterium. The statue of the saint on the apex of the pediment of the western front of St Paul's is an acroterium; the other statues may be called acroteral figures.

AMPHIPROSTYLE (Gr. αμφι, around or about, and *prostyle*, *q. v.*) A temple with a portico at each end is said to be amphiprostylar. This term would be more correctly applied to a structure having projecting porticoes on all its sides, especially if it be equilateral like the *Bourse* or Exchange at Paris, allowing no distinction of flanks or wings to make it peripteral. See Plate LV. fig. 3 and 4.

ANNULET (Lat. *annulus*, a ring). This term is applied to the small fillets or bands which encircle the lower part of the Doric capital immediately above the neck or trachelium.

ANTÆ (probably from the Gr. αντιος, or some other derivative of the preposition αντι, for, or opposite to; it has no singular), the pier-formed ends of the walls of a building as in the portico of a Greek temple. A portico is said to be *in antis* when columns stand between antæ, as in the temple of Theseus, supposing the peristyle or surrounding columns removed. Plate LIV., fig. 1, 2, and 3.

ANTEFIXÆ (Lat. *ante*, before, and *fixus*, fixed), upright blocks with an ornamented face placed at regular intervals on a cornice. Antefixæ were originally adapted to close and hide the lower ends of the joints of the covering tiles on the roof of a temple as they appear in the examples. Plate LIII. fig. 1, 2, and 4; and Plate LV. fig. 3.

APOPHYGE (Gr. αποφυγη, a flying off), the lowest part of the shaft of an Ionic or Corinthian column, or the highest member of its base if the column be considered as a whole. The apophyge is the inverted cavetto or concave sweep, on the upper edge of which the diminishing shaft rests. Plate LXII. fig. 1.

APTERAL (Gr. α priv. and πτερον, a wing), a temple without columns on the flanks or sides. The Greek Ionic temple, Plate LV., is apteral.

ARÆOSTYLE (Gr. αραιος, rare or weak, and στυλος, a column), a wide intercolumniation. (See EUSTYLE.) The space assigned to this term is four diameters.

ARÆOSYSTYLE (compounded of *aræostyle* and *systyle*, *q. v.*) This term is used to express the arrangement attendant on coupled columns, as in the western front of St Paul's Cathedral. Plate LXIV. fig. 1.

ARCADE, a series of arches.

ARCH (Lat. *arcus*, a bow), a construction of separate or distinct blocks or masses of any hard material, cut wedgewise, and arranged in a bowed form, so as to bear from end to end horizontally, or across an opening, though abutting or being supported only at the ends.

ARCHITRAVE (Gr. αρχη, chief, and Lat. *trabs*, a beam), the chief beam,—that part of the entablature which rests immediately on the heads of the columns, and is surmounted by the frieze; it is also called the epistylium or epistyle. Plate LXII. fig. 1. The moulded enrichment on the sides and head of a door or window is called an architrave.

ARCHIVOLT. This term is a contraction of the Italian *architrave voltato*. It is applied to the architrave moulding on the face of an arch, and following its contour.

ARRIS, the sharp edge or angle in which two sides or surfaces meet.

ASTRAGAL (Gr. αστραγαλος, a vertebral joint), a convex moulding. This term is generally applied to small mouldings, and torus to large ones of the same form. See TORUS.

ATTIC, a low story above an entablature, or above a cornice which limits the height of the main part of an elevation. The etymology of this term is unsettled; probably the upper range of columns in a Greek hypæthral temple (see Plate LIII. fig. 1.; and see also *Archæologia*, vol. xxiii. p. 412), was called ατειχον or ατοιχον, from having no coherent wall; whence the Latin *atticum*, and its application to a story superimposing the general ordinance. Otherwise such a thing is unknown in Greek architecture; but it is very common in both Roman and Italian practice. What is here termed the tholobate in St Peter's and St Paul's Cathedrals are generally termed attics.

BALUSTER, a small column or pier supporting the coping in a pierced parapet: the parapet itself when pierced is hence called a balustrade.

BAND or TÆNIA, nearly synonymous with Fillet, *q. v.* This term is, however, most generally applied to that listel in the Doric entablature which separates the frieze from the architrave, and connects the lower parts of the triglyphs.

BASE (Gr. βασις). The congeries of mouldings generally placed under the shaft of an Ionic or Corinthian column is called its base. Plate LXII. fig. 1. The term is applied also to the lowest part of a pedestal or stylobate; to the vertical moulded fittings which go round walls on the floor; and generally to everything that is put lowest, for anything to rest on.

BASEMENT. A basement story is a story in any building placed below the level of the ground on the outside of and about the building. Basement applied specially, as architects apply it, means the compartment in the elevation of a building upon which any columnar pilastraded or arcaded ordinance may rest; as in the Strand front of Somerset House, of which the basement begins at the level of the floor of the vestibule, being about that of the street pavement, and extends upwards to half the height of the adjoining building east and west.

BATTER (Fr. *battre*, to beat). Building over in projecting courses, like inverted steps, is termed battering, gathering, or corbelling over. The term is often applied to the converse operation of throwing back, as in a revetement or retaining wall.

† BATTLEMENT, a pierced or machicolated parapet.

† BAY. The space between the mullions of a window, between piers, and between the principal beams of a roof, floor, or ceiling, is a bay. The term Bay is also applied to a projected window or compartment of windows which forms on the inside a bay. Such a compartment in a shop is vulgarly called a Bow-window.

BEAD, a small cylindrical moulding of frequent use. Plate LV.

[1] Those marked thus † are either entirely, or almost entirely, peculiar to Pointed Architecture.

BED-MOULD the congeries of mouldings which is under the projecting part of almost every cornice, and of which indeed it is a part. Plate LXII. fig. 1.

BELL, is a term applied to the solid cove of a Corinthian or other foliated capital to a column, being, indeed, the basket of the pretty Vitruvian fable of the invention of the Corinthian capital.

BLOCKING-COURSE, a deep but slightly projecting course in an elevation, to act as cornice to an arcade, or to separate a basement from a superior story. (See STRING-COURSE.)

† BOSS, a sculptured knob which is placed on the intersections of ribs in groined ceilings.

† BUTTRESS, the projected piers against the quoins of towers, and against the ordinary piers of walls, to strengthen them, and receive the outward thrust of the inner transverse arches.

CABLING. The flutes of columns are said to be cabled when they are partly occupied by solid convex masses, or appear to be refilled with cylinders after they had been formed.

† CANOPY, a covering or hood, the enriched projecting head to a niche or tabernacle. The tablet or drip-stone, whether straight or circular, over the heads of doors or windows, if enriched, is called a canopy.

CAPITAL, CAP (Lat. Caput, the head), the spreading, moulded, voluted, foliated, or otherwise enriched head of a column. Plate LXII. fig. 1. The term *cap* is applied, in contradistinction, to the congeries of mouldings which forms the head of a pier or pilaster.

CARYATIDES. Human female figures used as piers, columns, or supports, are called *Caryatides;* and, adjectively, *Caryatic* is applied to the human figure generally, when used in the manner of Caryatides. Plate LVI. fig. 4 and 6.

CASSOON (Ital.), a deep panel or coffer in a soffit or ceiling. This term is often written, after the French, *caisson*, whereas we derive it directly from the Italian *cassone*, the augmentative of *cassa*, a chest or coffer.

CATHETUS (Gr. καθετος, a perpendicular line). The eye of the volute is so termed because its position is determined, in an Ionic or voluted capital, by a line let down from the point in which the volute generates.

CAULICULUS (Lat. a stalk or stem), the inner scrolls or tendrils of the Corinthian capital are called *Cauliculi.* It is not uncommon, however, to apply this term to the larger scrolls or volutes of the same also. Plate LXII. fig. 1.

CAVETTO (Ital. *cavare*, to dig out), a moulding whose form is a simple concave, and impending. Plate LVII.

CELLA (Lat.), the cell or interior of a Cleithral temple. The Greek term is Naos, *q. v.*

CHAMFER. An edge or arris taken off equally on the two sides which form it, leaves what is called a *chamfer.* or a *chamfered edge.* If the arris be taken off more on one side than the other, it is said to be splayed or bevelled.

† CINQUEFOIL, tracery in five foliations or featherings. The windows in the towers of Westminster Hall, Plate LXXI., are cinquefoiled.

CLEITHRAL (*vide* CLEITHROS). This is used of a covered Greek temple, in contradistinction to *Hypæthral*, which designates one that is uncovered.

CLEITHROS (Gr. κλειθρος, an inclosed or shut-up place). A temple whose roof completely covers or incloses it is a Cleithros. Plate LIV. fig. 1, 2, 3; and Plate LV. fig. 1 2, 3, and 4.

COFFER, a deep panel in a ceiling.

COLUMN (Lat. *columna*), a tapering cylindrical mass, placed vertically on a level stylobate, in some cases with a spreading congeries of mouldings called a base, and having always at its upper and smaller end a dilating mass called a capital. Columns are either insulated or attached. They are said to be attached or engaged when they form part of a wall, projecting one half or more, but not the whole of their substance. Plate LV. fig. 1 exhibits insulated and fig. 2 attached columns. See also Plate LXII. fig. 1.

CONSOL or CONSOLE, a bracket or truss, generally with scrolls, or volutes, at the two ends, of unequal size and contrasted, but connected by a flowing line from the back of the upper one to the inner convolving face of the lower.

COPING, the covering course or cornice of a wall or parapet. The term *coping* is generally applied to a plain, slightly projected, covering course, and *cornice* to a larger moulded coping.

† CORBEL, a knob, boss, or consol, projecting from a vertical face, to act as a prop or support. Its jutting or overhanging has induced the application of the term to describe the projecting of one thing over another.

CORNICE (Gr. κορωνις, the highest part, that which is placed last on a building), the highest part of an entablature—that which rests on the frieze. Plate LXII. fig. 1. The term *cornice* is very generally applied to any bold congeries of mouldings occupying the highest place in a composition, whether external or internal. A plain covering to a wall or parapet is called a coping, *q. v.*

CORONA (*vide* CORNICE). This term is applied to the deep vertical face of the projected part of the cornice between the bed-mould and the covering mouldings. Plate LXII. fig. 1.

COVE—COVING. The moulding called the cavetto,—or the Scotia inverted,—on a large scale, and not as one of a mere moulding in the composition of a cornice, is called a cove or a coving.

† CROCKET (probably from the old English word *crok*, a curl), an ornament of foliage or animals running up the back of a pediment, arch, pinnacle, or spire, from the corbets below to the finial above, in which latter the crockets on both sides appear to merge. Plate LXXI. fig. 3 and 5. In the earlier examples the crocket is a mere curl, or bent tendril, with an enriched end.

CUPOLA (Ital. *cupo*, concave, profound), a spherical or spheroidal covering to a building, or to any part of it. Plate LX. fig. 2, 3, and 4; Plate LXV.; and Plate LXX. fig. 2.

† CUSP (Lat. *cuspis*, a spear), the points in which the foliations of tracery finish. These are sometimes themselves enriched, and are sometimes plain.

CYCLOSTYLE (Gr. κυκλος, a circle, and στυλος, a column). A structure composed of a circular range of columns without a core is cyclostylar; for with a core the range would be a peristyle. This is the species of edifice falsely called by Vitruvius Monopteral. (See MONOPTEROS.)

CYMA (Gr. κυμα, a wave), the name of a moulding of very frequent use. It is a simple, waved line, concave at one end and convex at the other, like an Italic *f.* In that manner it is called a cyma-recta; but if the convexity appear above, and the concavity below on the right hand, it is then a cyma-reversa. Plate LVII.

CYMATIUM. When the crowning moulding of an entablature is of the cyma form, it is termed the Cymatium.

CYRTO-PROSTYLE. An alternation of Cyrtostyle (*q. v.*), but indicating more clearly than Cyrtostyle does an external projection.

CYRTOSTYLE (Gr. κυρτος, convex, and στυλος, a column), a circular projecting portico. Such are those of the transept entrances to St Paul's Cathedral, Plate LXV. fig. 1.

DADO or DIE, the vertical face of an insulated pedestal between the base and cornice or surbase. It is extended also to the similar part of all stereobates which are arranged like pedestals in Roman and Italian architecture.

DECASTYLE (Gr. δεκα, ten, and στυλος, a column), a portico of ten columns in front. (See note to the term HEXASTYLE.) The portico to University College, London, is

of this description; more particularly described, it is decaprostyle and recessed.

DENTIL (Lat. *dens*, a tooth). The cogged or toothed member, so common in the bed-mould of a Corinthian entablature, is said to be dentilled; and each cog or tooth is called a dentil. Plate LXII. fig. 1.

DESIGN. Architects apply this term to what is vulgarly called a plan, intending by it the scheme or design of a building in all its parts, the term *plan* having a distinct application to a technical portion of the design. (See PLAN.) The plans, elevations, sections, and whatever other drawings may be necessary for an edifice, exhibit the design.

DETAIL. As used by architects, detail means the smaller parts into which a composition may be divided. It is applied generally to mouldings and other enrichments, and again to their minutiæ.

DIAMETER (superior and inferior). The greater diameter of the shaft of a column is technically termed its inferior, because it is that of the lower end; and the lesser, that of the upper end, its superior diameter.

DIASTYLE (Gr. δια, through, and στυλος, a column), a spacious intercolumniation, to which three diameters are assigned. (See EUSTYLE.)

DIPTERAL. (See DIPTEROS.)

DIPTEROS (Gr. δις, twice, and πτερον, a wing), a double-winged temple. The Greeks are said to have constructed temples with two ranges of columns all round, which were called dipteroi. A portico projecting two columns and their interspaces is of dipteral or pseudo-dipteral arrangement. See description of fig. 3, Plate LIV.

DISTYLE (Gr. δις, twice, and στυλος, a column), a portico of two columns. This term is not generally applied to the mere porch with two columns, but to describe a portico with two columns in antis. The elevation of the pronaos of the hexastyle peripteral temple, Plate LIV. fig. 2, exhibits an example of distyle *in antis*.

DITRIGLYPH (Gr. δις, twice, and triglyph, *q. v.*), an intercolumniation in the Doric order, of two triglyphs. (See MONOTRIGLYPH.)

DODECASTYLE (Gr. δωδεκα, twelve, and στυλος, a column), a portico of twelve columns in front. (See note to HEXASTYLE.) There is no portico of this description in London at present. The lower one of the west front of St Paul's Cathedral (Plate LXIV.) is of twelve columns, but they are coupled, making the arrangement pseudo-dodecastyle. (See PSEUDO-PROSTYLE.) The Chamber of Deputies in Paris has a true dodecastyle.

DOME (Gr. δωμα, a structure of any kind; whence the Latin *domus*, a house or temple), a cupola or inverted cup on a building. The application of this term to its generally received purpose is from the Italian custom of calling an archiepiscopal church, by way of eminence, *Il duomo*, the temple; for to one of that rank, the cathedral of Florence, the cupola was first applied in modern practice. The Italians themselves never call a cupola a dome: it is on this side of the Alps the mistake has arisen, from the circumstance, it would appear, that the Italians use the term with reference to those structures whose most distinguishing feature is the cupola, tholus, or (as we now call it) dome. (See CUPOLA.)

† DRIPSTONE, the moulding or cornice which acts as a canopy to doors and windows. Horizontal running mouldings are sometimes called tablets and sometimes dripstones.

DROPS. (See GUTTÆ.)

ECHINUS (Gr. εχινος, an egg), a moulding of eccentric curve, which (when it is carved) being generally cut into the forms of eggs and anchors alternating, the moulding is called by the name of the more conspicuous. It is the same as Ovalo, *q. v.*

ELEVATION, the front, or *façade* as the French term it, of a structure. A geometrical drawing of the external upright parts of a building. Architects speak of front, back-front, and side or end elevations.

ENTABLATURE or INTABLATURE (Lat. *in*, upon, and *tabula*, a tablet). The superimposed horizontal mass in a columnar ordinance, which rests upon the tablet or abacus of a column, is so called. It is conventionally composed of three parts, architrave, frieze, and cornice, *q. v.* Plate LXII. fig. 1.

ENTASIS (Gr. εντασις, a stretching or swelling). Columns are said to have entasis when they do not diminish regularly, but in a curved line.

EPISTYLIUM or EPISTYLE (Gr. επι, upon, and στυλος, a column). This term may with propriety be applied to the whole entablature, with which it is synonymous; but it is restricted in use to the architrave or lowest member of the entablature.

ESCAPE, a familiar English equivalent for the term Apophyge, *q. v.*

EUSTYLE (Gr. ευ, well, and στυλος, a column), a species of intercolumniation, to which a proportion of two diameters and a quarter is assigned. This term, together with the others of similar import,—pycnostyle, systyle, diastyle, and aræostyle,—referring to the distances of columns from one another in composition, is from Vitruvius, who assigns to each the space it is to express. It will be seen, however, by reference to them individually, that the words themselves, though perhaps sufficiently applicable, convey no idea of an exactly defined space, and by reference to the columnar structures of the ancients, that no attention was paid by them to such limitations. It follows, then, that the proportions assigned to each are purely conventional, and may or may not be attended to without vitiating the power of applying the terms. Eustyle means the best or most beautiful arrangement; but as the effect of a columnar composition depends on many things besides the diameter of the columns, the same proportioned intercolumniation would look well or ill according to those other circumstances; so that the limitation of eustyle to two diameters and a quarter is absurd, and so it is in the case of the other similar terms. With Doric intercolumniation it is different, as may be seen by reference to the word MONOTRIGLYPH.

FAÇADE. (See ELEVATION.)

FASCIA (Lat. a band). The narrow vertical bands or broad fillets into which the architraves of Corinthian and Ionic entablatures are divided, are called fasciæ or fascias; and the term is generally applied to any similar member in architecture.

† FEATHERINGS. (See FOLIATIONS.)

FILLET, a narrow vertical band or listel, of frequent use in congeries of mouldings, to separate and combine them, and also to give breadth and firmness to the upper edge of a crowning cyma or cavetto, as in an external cornice. The narrow slips or breadths between the flutes of Corinthian and Ionic columns are also called fillets.

† FINIAL (Lat. *finis*, the end). The term is equivalent to the Greek Acroterium. It is applied to the carved apex of pediments, piers, pinnacles, and canopies.

FLUTE, a concave channel. Columns whose shafts are channelled are said to be fluted, and the flutes are collectively called flutings.

† FOLIATIONS or FEATHERINGS, small arches meeting in points or cusps, which are plain or enriched. They are used as an enrichment in tracery, and are distinguished as trefoils, quatrefoils, and cinquefoils, as the case may be.

FRIEZE (Ital. *fregio*, from the Lat. *Phrygionius*, enriched or embroidered), that portion of an entablature between the cornice above and the architrave below. Plate LXII.

Glossary.

fig. 1. It derives its name from being the recipient of the sculptured enrichments either of foliage or figures which may be relevant to the object of the structure. The frieze is also called the zoöphorus, *q. v.*

Frontispiece, the front or principal elevation of a structure. This term, however, is generally restricted in application to a decorated entrance.

Gable. When a roof is not hipped or returned on itself at the ends, its ends are stopped by carrying up the walls under them in the triangular form of the roof itself. This is called the gable, or, indeed, the pediment. The latter term, however, is restricted to the ornamental and ornamented gable; and gable itself is applied to a plain triangular end.

Glyph. (See Triglyph.)

Gradino (Ital. dim. of *gradus*, a step). Architects frequently use the plural of this term, gradini, and to gradinate, instead of the English, steps, and to graduate, perhaps without sufficient reason, though they find them useful to distinguish what they intend from the meaning of the latter words in their ordinary acceptation.

Groining. In vaulting or arching over from insulated piers, the cross vaults meet in angles, and lead to a common centre or apex. This is called groining.

Guiloche or Guilochos (Gr. γυιον, a member, and λοχος, a snare). An interlaced ornament like network, used most frequently to enrich the torus. Plate LVII.

Guttæ (Lat. drops). The small cylindrical drops used to enrich the mutules and regulæ of the Doric entablature are so called.

Helix (Gr. ἑλιξ, a wreath or ringlet), used synonymously with Cauliculus, *q. v.* It forms in the plural Helices.

Hemiglyph (Gr. ἡμισυς, half, and γλυφη, an incision or channel). The half-channels, or rather chamfered edges, of a triglyph tablet, may be so called. The two hemiglyphs are included to make the third channel, and complete the triglyph. (See Triglyph.)

Hexastyle (Gr. ἑξ, six, and στυλος, a column). A portico of six columns in front[1] is of this description. Most of the churches in London which have porticoes have hexaprostyles. (See Prostyle.)

Hypæthral. (See Hypæthros.)

Hypæthros (Gr. ὑπο, under, and αιθρα, the air), a temple open to the air, or uncovered. The Greeks frequently made the temples of the supreme divinities hypæthral. For instance, those of Jupiter Olympius at Agrigentum in Sicily, of Neptune at Pæstum, and of Minerva Parthenon at Athens, are all of this description. The term may be the more easily understood by supposing the roof removed from over the nave of a church in which columns or piers go up from the floor to the ceiling, leaving the aisles still covered. In that case it would be hypæthral, after the manner of the Greek hypæthros. The Pantheon in Rome having an opening in the centre of the dome, is thereby rendered hypæthral. See Plates LIII. and LX. fig 4 and 5.

Hypogea (Gr. ὑπο, under, and γη, the earth). Constructions under the surface of the earth, or into the sides of a hill or mountain, are hypogea.

Hypotrachelium (Gr. ὑπο, under, and τραχηλος, the neck), the moulding or the groove at the junction of the shaft with the capital of a column. In some styles the hypotrachelium is a projecting fillet or moulding, and in others, as the Doric, it is composed of a channel or groove, and sometimes of more than one. Plate LXII. fig. 1.

Ichnography (Gr. ιχνος, a footstep or track, and γραφη, a description or representation). A plan, or the representation of the site of an object on a horizontal plane, is its ichnography. The term *plan* (*q. v.*) is, however, much more frequently used.

Impost (Lat. *impositus*, laid upon). The horizontal congeries of mouldings forming the capital of a pier, or edge pilaster, which has to support one leg of an arch, is called the impost; sometimes, and more conveniently, this term is used for the pilaster itself, when its capital is called the impost cap or impost mouldings.

Intercolumniation (Lat. *inter*, between, and column, *q. v.*) The distance from column to column, the clear space between columns, is called the intercolumniation.

Jamb, the side-post or lining of a doorway or other aperture. The jambs of a window outside the frame are called reveals.

† Label, the level moulding or dripstone over a door or window, common in the later Pointed works. It is generally turned down at the ends at right angles, and slightly returned again horizontally and outwards.

Lacunar (Lat.), a panelled or coffered ceiling or soffit. The panels or cassoons of a ceiling are more classically called *lacunaria.*

† Lancet. A term familiarly applied to the simplest form of the Pointed arch, which is that of the outer end of the surgical instrument, the lancet.

† Lantern (Lat. *lanterna*), a turret raised above a roof or tower, and very much pierced, the better to transmit light. In modern practice this term is generally applied to any raised part in a roof or ceiling, containing vertical windows, but covered in horizontally.

Metope (Gr. μετοπη, a middle space), the square recess between the triglyphs in a Doric frieze. It is sometimes occupied by sculptures. Plates LIII. and LIV. fig. 4.

Mezzanine (Ital. *mezzanino*, dim. of *mezzo*, the middle), a low story between two lofty ones. It is called by the French entresol, or inter-story.

Mitre. A moulding returned upon itself at right angles is said to mitre. In joinery, the ends of any two pieces of wood of corresponding form cut off at 45°. necessarily abut upon one another so as to form a right angle, and are said to mitre.

Modillion (Lat. *modulus*, a measure of proportion), so called because of its arrangement in regulated distances; the enriched block or horizontal bracket generally found under the cornice of the Corinthian entablature. Plate LXII. fig 1. Less ornamented, it is sometimes used in the Ionic. See also Mutule.

Module (Lat. *modulus*, from *modus*, a measure or rule). This is a term which has been generally used by architects in determining the relative proportions of the various parts of a columnar ordinance. The semidiameter of the column is the module, which being divided into thirty parts called minutes, any part of the composition is said to be of so many modules and minutes, or minutes alone, in height, breadth, or projection. The whole diameter is now generally preferred as a module, it being a better rule of proportion than its half.

Monopteral. (See Monopteros.)

Monopteros (Gr. μονος, one, or single, and πτερον, a wing). This term is incorrectly used by Vitruvius to describe a temple composed of a circular range of columns supporting a tholus, cupola, or dome, but without walls. (See Peripteral.) Such an edifice would be more correctly designated as Cyclostylar, *q. v.*

Glossary.

[1] The words "in front" are used to prevent the mistake which might arise from a supposition that all the columns in a portico should be counted to designate it. The porticoes of the churches of St Martin-in-the-Fields, and St Mary-le-bone, in London, for instance, have each eight columns, but are hexastyle nevertheless, there being but six in their front rows respectively.

Glossary.

MONOTRIGLYPH (Gr. μονος, one, or single, and *triglyph*, *q. v.*) The intercolumniations of the Doric order are determined by the number of triglyphs which intervene, instead of the number of diameters of the column, as in other cases; and this term designates the ordinary intercolumniation of one triglyph. Plate LIV. fig. 1.

MOULDINGS, eccentric curves of various kinds, intended to enrich and ornament, by producing light and shade, and obviating the monotony attendant on many flat and angular surfaces. They may be variously carved to increase their efficiency. The most usual forms of mouldings are called the cyma-recta and reversa, cavetto, scotia, torus, astragal or bead, and the echinus or ovalo, *q. v.* Plate LVII. In Pointed architecture, mouldings are not limited either to those names or to the forms they are intended to designate, nor indeed is any other style, except by absurd custom and authority.

† MULLION, the columnar vertical bar used to divide a window into breadths; the trunk out of which tracery flows.

MUTULE (Lat. *mutulus*, a stay or bracket), the rectangular impending blocks under the corona of the Doric cornice, from which guttæ or drops depend. Mutule is equivalent to modillion, but the latter term is applied more particularly to enriched blocks or brackets, such as those of Ionic and Corinthian entablatures.

NAOS (Gr. ναος, a temple). This term is sometimes used instead of the Latin cella, as applied to the interior; strictly, however, it means the body of the edifice itself, and not merely its interior or cell.

NEWEL, the solid or hollow column or cylinder which bears up the handrail of a staircase at the foot and in the most material parts. It means also the core or hollow, as the case may be, about which a circular staircase winds.

NICHE, a concave recess in a wall, with a straight or circular head. Niches are generally made to receive statues, vases, &c.

OCTASTYLE (Gr. οκτω, eight, and στυλος, a column). A portico of eight columns in front. (See note to HEXASTYLE.) There is no portico in London of this description at present, though the upper one of the west front of St Paul's (Plate LXIV.) is of eight columns; but they are coupled, making the arrangement tetrastyle. It may indeed be called a pseudo-octa-prostyle. (See PSEUDO-PROSTYLE.)

OGEE, the vulgar name for the Cyma, *q. v.*

OPISTHODOMUS (Gr. οπισθεν, behind, and δομος, a house or other edifice), the part behind a Greek temple corrresponding with the Pronaos before it. (See PRONAOS.)

ORDER. A column with its entablature and stylobate is so called. (Plate LXII. fig. 1.) The term is the result of the dogmatic laws deduced from the writings of Vitruvius, and has been exclusively applied to those arrangements which they were thought to warrant.

ORDINANCE, a composition of some particular order or style. It need, not, however, be restricted to a columnar composition, for it will apply to any species which is subjected to conventional rules for its arrangement.

ORTHOGRAPHY (Gr. ορθος, straight or true, and γραφη, a description or representation). A geometrical elevation of a building or other object, in which it is represented as it actually exists, or may exist, and not perspectively, or as it would appear, is called its orthography.

ORTHOSTYLE (Gr. ορθος, straight or true, and στυλος, a column), any straight range of columns. This is a term suggested to designate what is generally but improperly called a peristyle, *q. v.;* that is, columns in a straight row or range, but not forming a portico.

OVALO (Ital.), egg-formed (see ECHINUS). This is the name most commonly applied to the moulding which appears to have originated in the moulded head of the Doric column, and, with an abacus, forming its capital.

PANEL, a compartment with raised margins, moulded or otherwise. Deep panels in a ceiling are called Cassoons and Lacunaria, *q. v.*

PARAPET (Ital. *parapetto*, against the breast or breast-high), the low breast-high wall which is used to front terraces and balconies, to flank bridges, &c. The most common application of the term in this country is to so much of the external walls of a house as stands above the flats and gutters of the roof behind.

PARASCENIUM, in a Greek theatre, the wall at the back of the stage.

PARASTAS (Gr. παραστας, standing before), antæ or end pilaster. This is the Greek term for which the Latin antæ is generally used. It has the same meaning, and they may be used alternatively. (See ANTÆ.)

PEDESTAL (Gr. πους, a foot, and στυλος, a column). An insulated stylobate is for the most part so called. The term is, moreover, generally applied to any parallelogramic or cylindrical mass, used as the stand or support of any single object, as a statue or vase.

PEDIMENT, that part of a portico which rises above its entablature to inclose the end of the roof, whose triangular form it takes. The cornice of the entablature, or its corona and part of the bed-mould only, with the addition of a cymatium, bounds its inclined sides, and gives it an obtuse angle at the apex. In pointed architecture, however, the angle of a pediment is for the most part acute.

† PENDENT (Lat. *pendens*, hanging). In some of the later works of the Pointed style, large masses depend from enriched ceilings, and appear to be formed by the other legs of intersecting arches: these are called pendents. They also occur in canopies. See Plate LXXI. fig. 1, 8, 9, 11, and 12.

PERIBOLUS (Gr. περι, around or about, and βαλλω, to throw), an inclosure. Any inclosed space is a peribolus; but the term is applied more particularly to the sacred inclosure about a temple. The wall forming the inclosure is also called the peribolus.

PERIPTERAL. (See PERIPTEROS.)

PERIPTEROS (Gr. περι, around or about, and πτερον, a wing). A temple or other structure with the columns of its end prostyles, or porticoes, returned on its sides as wings, at one intercolumniation distant from the walls. Almost all the Doric temples of the Greeks were peripteral. The term is, however, incorrectly applied by Vitruvius to peristylar structures, though it is clear that a perfectly round building, such as he describes to be peripteral, cannot be said to be winged or to have wings.

PERISTYLAR, having a peristyle. (See PERISTYLE.)

PERISTYLE (Gr. περι, around or about, and στυλος, a column), a range of columns encircling an edifice, such as that which surrounds the cylindrical drum under the cupola of St Paul's. The columns of a Greek peripteral temple form a peristyle also, the former being a circular, and the latter a quadrilateral peristyle. The same term is generally but incorrectly applied to a range of columns in almost any situation when they do not form a portico. (See ORTHOSTYLE.

PIER. The solid parts of a wall between windows, and between voids generally, are called piers. The term is also applied to masses of brickwork or masonry which are insulated to form supports to gates or to carry arches.

PILASTER (Lat. *pila*, a pillar, and the Ital. augmentative *astro*, which indicates an inferior quality), an inferior sort of column or pillar; a projection from or against a pier, having the form and decorations of antæ, when used correctly; but too frequently they have capitals, like those of columns, assigned them.

PILLAR (Lat. *pila*, and Ital. *piliere*), a columnar mass of no particular form. Columns are vulgarly called pillars; but

Glossary.

architects make a distinction, restricting this term to such pillars as do not come within the description of a column. (See Column.)

Pillowed. A swollen or rounded frieze is said to be pillowed or pulvinated.

† Pinnacle, the slender tapering head of a turret or buttress. A small spire, or the head of a spire or steeple.

Plan, a horizontal geometrical section of the walls of a building; or indications, on a horizontal plane, of the relative positions of the walls and partitions, with the various openings, such as windows and doors,—recesses and projections, as chimneys and chimney-breasts,—columns, pilasters, &c. This term is often incorrectly used in the sense of Design, *q. v.*

Planceer is sometimes used in the same sense as soffit, but incorrectly, as it is from the French *plancher*, to board or floor. It is more particularly applied to the soffit of the corona in a cornice.

Plinth (Gr. πλινθος, a square tile). In the Roman orders the lowest member of the base of a column is square and vertically faced; this is called a plinth.

Podium, strictly something upon or against which the foot may be placed; and in this sense probably it was applied to the wall which bounds the arena of an amphitheatre, and is thereby at the feet of the most advanced of the spectators.

Polytriglyph (Gr. πολυς, many, and triglyph, *q. v.*) An intercolumniation in the Doric order of more than two triglyphs. (See Monotriglyph and Ditriglyph.)

Portico (an Italicism of the Lat. *Porticus*), an open space before the door or other entrance to any building, fronted with columns. A portico is distinguished as prostyle, or *in antis*, as it may project from or recede within the building, and is designated with either of these terms by the number of columns its front may consist of. (See Distyle, Tetrastyle, Hexastyle, Octastyle, &c.)

Porticus (Lat. See Portico). In an amphiprostylar or peripteral temple, this term is used to distinguish the portico at the entrance from that behind, which is called the posticum.

Posticum (Lat). A portico behind a temple. (See Porticus and Portico.)

Pronaos (Gr. προ, before, and ναος, a temple). The inner portico of a temple, or the space between the porticus, or outer portico, and the door opening into the cella. This is a conventional use of the term; for, strictly, the pronaos is the portico itself.

Propylæum (Gr. προ, before, and πυλη, a portal), any structure or structures forming the entrance to the peribolus of a temple; also the space lying between the entrance and the temple. In common usage this term, in the plural (propylæa), is almost restricted to the entrance to the Acropolis of Athens, which is known by it as a name.

Propylon, an alternation in the Greek form of Propylæum (*q. v.*) in the Latin of Vitruvius.

Proscenium, in a Greek theatre, the stage.

Prostyle (Gr. προ, before, and στυλος, a column). A portico in which the columns project from the building to which it is attached is called a prostyle. It is tautologous to say a prostyle portico,—a prostyle is a portico. Custom, however, seems to warrant the impropriety, for the word portico is always superadded. In determining the number of columns of which a portico consists, the Greek numerals are prefixed to the term Style, *q. v.*, and prostyle is repeated. It would be more concise, and, at the least, equally correct, to put the numeral before prostyle, and say tetra-prostyle, hexa-prostyle, &c., instead of tetrastyle-prostyle, &c.; as the custom is; that mode is adopted in this article throughout.

Pseudo-dipteral (Gr. ψευδης, false, and dipteral, *q. v.*), false, double-winged. When the inner row of columns of a dipteral arrangement is omitted, and the space from the wall of the building to the columns is preserved of the consequent double projection, it is pseudo-dipteral. The portico of University College London is pseudo-dipterally arranged, the returning columns on the ends or sides not being carried through behind those in front.

Pseudo-peripteral (Gr. ψευδης, false, and peripteral, *q. v.*), false-winged. A temple having the columns on its flanks attached to the walls, instead of being arranged as in a peripteros, is said to be pseudo-peripteral.

Pseudo-prostyle (Gr. ψευδης, false, and prostyle, *q. v.*) This is a term not in general use, but is here suggested to designate a portico projecting less than the space from one column to another, as the western porticoes to St Paul's Cathedral, and the portico to the East India House, in London; but that they are recessed also, and therefore may be described as pseudo-prostyle and recessed. The front of Trinity Church in the New Road, near the Regent's Park, London, presents a mere pseudo-prostyle.

Pulvinated (Lat. *pulvinus*, a cushion or bolster), a term used to express the swelling or bolstering of the frieze, which is found in some of the inferior works of the Roman school, and is common in Italian practice. It is used indifferently with pillowed.

Pycnostyle (Gr. πυκνος, dense, and στυλος, a column), columns thickly set. The space or intercolumniation implied by this term is one diameter and a half. (See Eustyle.)

† Quatre-Foil, tracery in four foliations or featherings, but applicable only to circular or square panels, and not to arches.

Quoin (Lat. *ancon*, an elbow or corner, whence the Fr. *coin*), an outer corner. The stones which are made to project from the regular surface of the walls at the outer angles of a building are technically called quoins. The front of the Farnese Palace exemplifies them. (See Plate LXVI.)

Regula (Lat.), a rule or square. The short fillet or rectangular block, under the tænia, on the architrave of the Doric entablature, is so called.

† Rose or Catherine-wheel Window, the large circular window filled with various tracery, which is common in the upper part of transept fronts in churches and cathedrals. Plate LXVIII. fig. 1.

Scotia (Gr. σκοτια, shadow or darkness), a concave moulding most commonly used in bases, which projects a deep shadow on itself, and is thereby a most effective moulding under the eye as in a base. It is like a reversed ovalo, or rather what the mould of an ovalo would present. Plate LVII.

Scroll, synonymous with volute. The term scroll is commonly applied to the more ordinary purposes, whilst volute is generally restricted to the scrolls of the Ionic capital.

Section, a drawing shewing the internal heights of the various parts of a building. It supposes it to be cut through entirely, so as to exhibit the walls, the heights of the internal doors, and other apertures; the heights of the stories, thicknesses of the floors, &c. It is one of the species of drawings necessary to the exhibition of a Design, *q. v.*

Shaft. The body or tapering cylindrical mass of a column, from the base below to the capital above, is so called. Plate LXII. fig. 1.

Sill or Sole (Lat. *solum*, a threshold, whence the Fr. *seuil*). The horizontal base of a door or window-frame is called its sill, though in practice a technical distinction is made between the inner or wooden base of the window-frame, and the stone base on which it rests,—the latter being called the sill of the window, and the former that of its

Glossary.

frame. This term is not restricted to the bases of apertures; the lower horizontal part of a framed partition is called its sill. It is sometimes incorrectly written cill.

SOFFIT (Ital. *soffitta*, a ceiling), the inverted horizontal face of anything. The horizontal face of an entablature resting on, and lying open between, the columns, is its soffit. The underface of an arch, where its thickness is seen, is its soffit.

SPANDREL. The unoccupied angles, or rather the excluded triangles, of a square described about a circle, are called spandrels; whence almost any triangular space is designated by the same term.

† SPIRE, the tapering mass which forms the summit of a steeple.

STEEPLE. This term is used in contradistinction to tower, the latter being upright, or nearly so, and terminating almost abruptly, or with pinnacles, and the steeple running to a point with sides converging from the base upwards, or from a certain height only.

STELE (Gr. στηλη, a cippus or small monument). The ornaments on the ridge of a Greek temple, answering to the antefixæ on the summit of the flank entablatures, are designated stelai.

STEREOBATE (Gr. στερεος, firm or solid, and βασις, a base or fulciment), a basement. It is here sought to make a distinction between this term and Stylobate, *q. v.*, by restricting the latter to its real import, and applying stereobate to a basement in the absence of columns.

STOA (Gr. στοα, a portico). This is the Greek equivalent for the Latin porticus and the Italo-English portico, *q. v.*

STRING or STRING-COURSE, a narrow, vertically-faced, and slightly projecting course in an elevation. If window-sills are made continuous, they form a string-course; but if this course is made thicker or deeper than ordinary window-sills, or covers a set-off in the wall, it becomes a blocking-course.

STYLE (Gr. στυλος, a column). The term style, in architecture, has obtained a conventional meaning beyond its simpler one, which applies only to columns and columnar arrangements. Eustyle, *q. v.*, is a graceful distribution of columns as to space, and so it may be taken to apply to any good and pleasing distribution of solids and voids in the composition of a structure. But Eustyle being a condition of style not always found, or not recognized, in all architectural compositions, the term is taken without the qualifying prefix, and is applied with such qualifications and descriptions as may be necessary to make it available to all classes of architectural composition. Style as a term in architecture must be understood to be in no sense the same word as style in literature.

STYLOBATE (Gr. στυλος, a column, and βασις, a base or fulciment), a basement to columns. (See STEREOBATE.) Stylobate is synonymous with pedestal, but is applied to a continued and unbroken substructure or basement to columns, while the latter term is confined to insulated supports.

SURBASE (Lat. *super*, whence the Fr. *sur*, above or upon, and *base*, *q. v.*), an upper base. This term is applied to what, in the fittings of a room, is familiarly called the chair-rail. It is also used to distinguish the cornice of a pedestal or stereobate, and is separated from the base by the dado or die.

SYSTYLE (Gr. συν, together with, and στυλος, a column), columns rather thickly set. An intercolumniation to which two diameters are assigned. (See EUSTYLE.)

TABERNACLE, a canopied recess or niche. The rich ornamental tracery forming the canopy, &c., to a tabernacle, is called tabernacle-work: it is common in the stalls and screens of cathedrals, and in them is generally open or pierced through.

† TABLET. Projecting mouldings, or moulded strings in the Pointed style, are better described as tablets than as cornices.

TÆNIA (Lat.) a band. (See BAND.)

TERMINAL. Figures of which the upper parts only, or perhaps the head and shoulders alone, are carved, the rest running into a parallelopiped, and sometimes into a diminishing pedestal, with feet indicated below, or even without them, are called terminal figures.

TETRAPROSTYLE. (See TETRASTYLE and PROSTYLE.)

TETRASTOÖN (Gr. τετρα, four, and στοα, a portico). An atrium or rectangular court-yard, having a colonnade or projected orthostyle on every side, is called a tetrastoön.

TETRASTYLE (Gr. τετρα, four, and στυλος, a column), a portico of four columns in front. (See note to HEXASTYLE.)

THOLOBATE (Gr. θολος, a dome or cupola, and βασις, a base or substructure), that on which a dome or cupola rests. This is a term not in general use, but it is not the less of useful application. What is generally termed the attic above the peristyle and under the cupola of St Paul's, would be correctly designated the tholobate. A tholobate of a different description, and one to which no other name can well be applied, is the circular substructure to the cupola of the Univ. Coll. London.

THOLUS or THOLOS (Gr.), a dome or cupola, or any round edifice. This is the only term used by Greek writers that can be supposed to apply to the conoidal chambers which approach, in internal form, to that of the modern cupola or dome, and is therefore made the Greek equivalent for those terms.

TORUS (Lat.), a protuberance or swelling, a moulding whose form is convex, and generally nearly approaches a semicircle. It is most frequently used in bases, and is for the most part the lowest moulding in a base. Plate LVII.

TOWER, a circular, square, or polygonal structure, with upright or slightly converging sides, running to a height equal to or greater than its diameter or base, and terminating abruptly or in horizontal lines. A tower may be flanked by buttresses whose pinnacles surmount it, and be superimposed by a turret, lantern, or spire.

† TRACERY. The transoms, mullions, and interlaced or flowing continuations of the latter, with their foliations in windows, on doors, panels, and in tabernacle-work, are so called. The ribs on groined ceilings, and almost all eccentric moulded enrichments, come under the same denomination.

TRACHELIUM (Gr. τραχηλος, the neck). In Doric and Ionic columns there is generally a short space intervening between the hypotrachelium and the mass of the capital, which may be called the trachelium or neck.

TRANSEPT. In a church of which the plan is in the form of a cross, the arms lying across at the intersection of the nave and chancel form the transept. Commonly each arm is spoken of as a transept, but strictly the transept is one.

† TRANSOM, the horizontal bar used to divide a mullioned window into heights; the straight and horizontal parts of tracery.

† TREFOIL, tracery in three foliations or featherings.

TRIGLYPH (G. τρεις, three, and γλυφη, an incision or channel). The vertically channelled tablets of the Doric frieze are called triglyphs, because of the three angular channels in them, two perfect and one divided; the two chamfered angles or hemiglyphs being reckoned as one. The square sunk spaces between the triglyphs on a frieze are called metopes.

TRUSS, a term in carpentry; but, probably by some abuse, it has been made to apply to consols, or ornamented corbels. (See CONSOL.)

Descriptions of Plates.

† TURRET, a small tower, or a tower of small base in proportion to its height. Turrets are sometimes placed on the angles of towers; but in the later works of the style they are attached to the angles of structures instead of buttresses, and they run up above their height in lieu of pinnacles.

TYMPANUM (Gr. τυμπανον). The triangular recessed space inclosed by the cornice which bounds a pediment. The Greeks sometimes placed sculptures representing subjects in connection with the purposes of the edifice, in the tympana of temples.

VAULT (Ital. *Voltato*, turned over). An arched ceiling or roof. A vault is, indeed, a laterally conjoined series of arches. The arch of a bridge is, strictly speaking, a vault. Intersecting vaults are said to be groined. (See GROINING.)

VOLUTE (Lat. *volutum*, from *volvo*, rolling up or over, convolving). The convolved or spiral ornament which forms the characteristic of the Ionic capital is so called. The common English term is scroll, *q. v.* Volute, scroll, helix, and cauliculus, are used indifferently for the angular horns of the Corinthian capital.

ZOÖPHORUS (Gr. ζωον, an animal, and φερω, to bear). This term is used in the same sense as frieze, and is so called because that part of the entablature is made the receptacle of sculptures which are frequently composed of various animals.

DESCRIPTIONS AND EXPLANATIONS OF THE PLATES.

Plate L. The view of the Parthenon in its present state is from an original drawing made on the spot in the year 1821, by Mr W. W. Jenkins. It consequently exhibits the appearance of the splendid ruin before the disasters of the last revolution befell it, as the restored view, under the same aspect, does of the structure in its original state. This is introduced as a frontispiece to the subject, as being an acknowledged master-work of architecture, as well as to enable the reader the better to understand the details of the style of which it is an example, and the composition of that class of structures of which it may be reckoned the principal.

Plate LI. This plate exhibits the varieties of columns and columnar composition which the ancient architecture of various countries presents, and is intended to elucidate their presumed derivation from the single pillar of the earliest records; together with specimens of ancient modes of structure.

Fig. 1 presents an example of the single pillar or stone of memorial, the Monolithon; fig. 2 of the Bilithon, the cromlech of the Celtic nations; fig. 3 of the Trilithon, an example afforded by Stonehenge; and fig. 4 exhibits the immediately succeeding arrangement of pillars, with a continuous entablature.

Fig. 5 shows the flank of the portico of the temple at Amada in Nubia, consisting of square piers or pillars as in fig. 4, and a cylindrical column, which is evidently formed of a similar pillar by working off its angles, the abacus and plinth remaining of the same size and form of which the pillars are.

Fig. 6, pillars with a plain entablature as in fig. 4, from the Rhamesseion at Thebes. The statues placed before the pillars most probably gave rise to the use of such figures to support an entablature, which these have the appearance of doing when seen in front.

Fig. 7, an early Egyptian columnar composition, from Thebes also. In this, as in the example at Amada, the square abacus shows the form and size of the original pillar out of which the singular bulbous column has been sculptured.

Fig. 8, piers of one of the cavern temples of Ellora. These likewise exhibit the tendency to the cylindrical form, and may be assumed as an example of the style of architectural columnar composition at the time they were executed.

Fig. 9, ancient Hindoo columnar piers, in the Mokundra Pass, from Colonel Tod's second volume of the *Annals of Rajast'han*. The similarity in character which exists between these and the piers at Ellora in the preceding example, tends to strengthen the remark accompanying them, and affords proof of their contemporaneousness.

Fig. 10, Doric columns and their architrave from the ruins at Corinth, being the earliest known example of their style.

Fig. 11, ancient Persian columns from Persepolis, in front and in profile, the latter showing the mode in which they were probably made to receive an entablature, though it is stated that the capitals are wrought on the backs in such a manner as to render it improbable that they were ever intended to have anything placed on them.

Fig. 12, columns in front of the rock sculptures at Mundore, in Marwar, from Colonel Tod's first volume.

Fig. 13, from the ruins of Bheems Chlori, also in the Mokundra Pass, from Colonel Tod's second volume. These present another variety of Hindoo columnar composition of early date, though later, it is probable, than the example, fig. 9, *supra*. Figs. 14 and 16 exhibit the modes of structure described in the text at page 440; and fig. 15 is a view of the entrance to the great pyramid at Memphis, from Denon, and shows the mode of its structure.

Plate LII. An example of the Egyptian style, sufficiently explained at pp. 436, 458, *et seq.*

Plate LIII. A Greek Doric octastyle, peripteral, and hypæthral temple, with the details of the Parthenon. The plan (fig. 3) is that of the Parthenon (*vide* Plate L.) slightly modified, the better to include the class to which it belongs. In the Parthenon, the opisthodomus has six columns, as in the pronaos, and not four *in antis*, as here laid down: this, however, exhibits the ordinary mode of arrangement. The internal columns are arranged in this plan as they are generally found in other similar structures; and the pedestal for the statue of the divinity is placed in its most probable position.

Fig. 1. shows part of the flank of the temple and the internal composition of the hypæthral cella with its upper range of columns or attic, of the inner chamber or treasury, and of the opisthodomos and posticum: much of this, however, is necessarily taken at a venture, because of the imperfect state of the remains of the Grecian edifices.

Fig. 2 exhibits an elevation of the opisthodomus behind the outer range of the portico, not according to the Parthenon, but *in antis.*

Fig. 3 is the plan. In front, on the left-hand side, is the entrance porticus; behind this is the pronaos; within the pronaos is the hypæthral naos or cella, the middle space between the columns being open; the spaces between the columns and the walls on either side are covered; doors (these are not generally laid down to the Parthenon, but are assumed as probable) lead to the inner chamber, said to be the treasury,—this is by some called the opisthodomus, into which it opens, and the opisthodomus stands in the same relation to the posticum that the pronaos does to the porticus.

Fig. 4 is the external order of the Parthenon; fig. 5, the profile of its corona to a larger scale, to show its de-

Descriptions of Plates.

tail; fig. 6, a half-capital of the same, enlarged also, with its annulets larger still.

Fig. 9 is the order of the pronaos; fig. 8, the profile of its corona enlarged; fig. 7, its capital enlarged, with the annulets still larger.

Fig. 10, the antæ cap enlarged; and fig. 12 a half-plan of a column of the Parthenon, showing the contour of its flutes. (*Vide* page 463, *et seq.*)

Plate LIV. A Greek Doric hexastyle, peripteral, and cleithral temple, with the details of the temple of Theseus at Athens.

Fig. 1, front elevation of the temple.

Fig. 2, section behind the outer range of the portico, showing the elevation of the pronaos.

Fig. 3, plan of the temple. The arrangement of the porticus here (to the left) is pseudo-dipteral; a space equal to two intercolumniations and the intervening column being left between the external range and the front of the pronaos,—the projection of the posticum is irregular.

Fig. 4, the external order of the temple of Theseus, with a half-plan of the column; fig. 5, the profile of the corona enlarged; fig. 6, half the capital enlarged; fig. 7, half the capital of the order of the pronaos enlarged also; fig. 9, the antæ, with profiles of the outer and inner entablatures of the pronaos,—this shows also the arrangement of the ceilings.

Fig. 10, enlarged profile of the antæ cap.

Fig. 11, inverted plan of part of the ceilings of the porticus and pronaos, showing the arrangement of the coffers, lacunæ, or cassoons.

Fig. 12, inverted plan of the planceer of the cornice, showing the form and arrangement of the mutules of the external entablature.

Fig. 13, is a plan of the triglyphs of the same on an external angle.

Figs. 8 and 14 are enlarged plans of the flutings of the columns, to show their contours. (*Vide* p. 463, *et seq.*

Plate LV. A Greek Ionic hexa-prostyle apteral temple, with details of the temple of Erechtheus at Athens.

Fig. 1, elevation of the portico.

Fig. 2, rear elevation of the temple, showing an attached tetrastyle *in antis*, with windows as they exist in that of the temple of Erechtheus.

Fig. 3, flank elevation. The dotted projection to the right of the posticum indicates the amphiprostylar arrangement, which is shown on the plan fig. 4 also, and in the same manner.

Fig. 5, the order of the temple of Erechtheus, except the two lowest steps of the stylobate, which may be easily supplied, to a larger scale, with indications of the carved mouldings, &c.

Figs. 6, 7, and 8 are enlarged profiles of those parts of the entablature which are immediately behind and above them.

Fig. 10, the antæ of the same example, showing the ornament which enriches its necking, and runs along the flank of the edifice; fig. 11, profile of the antæ cap enlarged.

Fig. 12, flank elevation of the capital; all the vertical beads in this are carved. Fig. 13, transverse section of the capital.

Fig. 14, half the longitudinal section of the capital.

Fig. 15, an inverted plan of the capital, showing the arrangement of the flutings.

Fig. 16, an inverted plan of one of the angular capitals. (*Vide* p. 465, *et seq.*)

Fig. 9, The Ionic volute, enlarged to show the mode of striking it, and the contour of its face.

Plate LVI. Fig. 1 the elevation, fig. 2 the plan, and fig. 3 the details, of the order of the Choragic Monument of Lysicrates at Athens. (*Vide* p. 466.)

Fig. 4 presents the elevation, and fig. 5 the plan, of the Caryatic prostyle, which is attached to the flanks of the temple of Erechtheus at Athens.

Fig. 6 shows the details of the hands and feet of the figure, and of the entablature and stereobate of the same. *Vide* (p. 467.)

Plate LVII. contains Greek and Roman mouldings, with their usual enrichments, all drawn from ancient examples, and detached profiles of them all, together with two examples of Greek and one of Roman ornament. The specimen of Greek ornament on the left hand of the centre is from the neck of the antæ cap of the tetrastyle portico on the flank of the temple of Erechtheus, generally known as that of Minerva Polias; and the other half of the same is the enrichment of the neck of the antæ of the temple of Erechtheus itself, as shown in Plate LIX. figs 3 and 10. The Roman specimen of ornament is that of the frieze of the temple of Antoninus and Faustina in Rome. (*Vide* Plate LVIII. Ex. 3 and p. 467 and 477.)

Plate LVIII. Four Roman examples of the Corinthian order. Ex. 1 is that of the temple of Jupiter Stator in Rome; Ex. 2 is that of the temple of Vesta at Tivoli (*vide* Plate LX. fig. 9); Ex. 3 is that of the temple of Antoninus and Faustina (*vide* Plate LX. figs. 6, 7, and 8); and Ex. 4 is the example of the portico of the Pantheon in Rome (*vide* Plate LX. figs. 2, 3, 4, and 5). To every example fig. 1 shows the details enlarged, the shafts being cut away; and fig. 2 the elevation of the column and entablature. In every case, also, the distance from the inner surface of the column fig. 2 to the vertical line dividing the examples is one half the intercolumniation at which that example is composed. (*Vide* p. 473, *et seq.*)

Plate LIX. Examples of the Roman orders. Ex. 1 is the Corinthian of the Temple of Mars Ultor; Ex. 2 the Composite of the Arch of Titus (*vide* Plate LX. fig. 11); Ex. 3 the Ionic of the Temple of Fortuna Virilis (*vide* Plate LX. fig. 12); and Ex. 4 the Doric of the Theatre of Marcellus, completed from that of the Colosseum. All of these are in Rome. Figs. 1, as in Plate LVIII., show the entablatures, capitals, and bases, &c., on an enlarged scale; and figs. 2 the complete elevation of each order, except their stylobates, some of which are not ascertained, and those which are may be obtained from the structures they are referred to in Plate LX. (*Vide* p. 473, *et seq.*)

Plate LXIV. Elevations, plans, and sections of sundry Roman edifices, all drawn to the same scale.

Fig. 1 is a longitudinal elevation of the Colosseum. (*Vide* p. 469.)

Fig. 2 is the front elevation, fig. 3 the flank elevation, fig. 4 a section, and fig. 5 the plan, of the Pantheon. The dotted lines before the recess opposite the entrance, fig. 5, show the places the outstanding columns originally occupied. (*Vide* pp. 469 and 470.)

Fig. 6 is the front elevation, fig. 7 the plan, and fig. 8 the flank elevation, of the temple of Antoninus and Faustina: of this the front steps and stylobate are restorations. (*Vide* p. 469, and Pl. LVIII. Ex. 3.)

Fig. 9 is the plan and elevation of the temple of Vesta at Tivoli; of this the antefixæ and roof are restorations. (*Vide* Pl. LVIII. Ex. 2.)

Fig. 10 is the plan and elevation of the triumphal arch of Septimius Severus. (*Vide* p. 469.)

Fig. 11 is a plan and elevation of the arch of Titus. (*Vide ut sup.* and Pl. LIX. Ex. 2.)

Fig. 12 is a plan and elevation of the temple of Fortuna Virilis. (*Vide* p. 469, and Pl. LXIII. Ex. 3.)

Plate LXI. Plans, sections, elevations, &c., of Roman mansions from Pompeii.

Descriptions of Plates.

Fig. 1 is a plan of one of the most extensive and most regular of the domestic structures of Pompeii, with its immediate vicinage; it is known as the house of Pansa. The following nomenclature is generally that of Sir William Gell:—1, The entrance or recessed porch; 2, the vestibule; 3, the cavædium or atrium; 4, the compluvium or well for receiving the rain from the roof covering this part of the house (*vide* fig. 2); 5, penaria, or perhaps cubicula; 6, alæ or wings; 7, tablinum or palour; 8, pinacotheca, or perhaps the library; 9, a passage from the first to the second atrium without passing through the tablinum; 10, cubiculum or bed-chamber; 11, peristylium or oicus—the house; 12, impluvium (*vide sup. in* 4, *et* fig. 2); 13, exhedræ or alæ—in these the siesta was taken—they were also used for conversation; 14, cellæ familiaricæ; 15, triclinium—here couches and seats were placed, and company received; 16, lararium or receptacle for the family gods; 17, cubiculum; 18, hall to the gynæceum or women's apartment; 19, the gynæceum—this is believed by some to be a distinct house, and not a part of that of Pansa; 20, porticus or pergula; 21, hortus or garden; 22, a passage from the oicus to the pergula and garden, to avoid the necessity of passing through the triclinium; 23, kitchen; 24, storeroom or larder; 25, an open court, communicating with the street by a doorway. This comprehends the whole of the apartments, &c., appropriated to domestic use—the residence; the other portions of the edifice are distinct from it. 26 is another smaller house; 27, a passage leading to the house of Pansa from the street on the right-hand side; all the places marked 28 are shops open to the street, as shown in the elevation, fig. 3; the rooms marked 29 are storerooms to the shops into which they open; 30 is a bakehouse, in which the mills, &c., are indicated as they exist; 31 is the oven; in the angle of the two adjoining streets on the left hand (32) is the shop of a seller of wine and hot drinks; 33 is a fountain. The walls indicated on the other sides of the streets surrounding the house, &c., of Pansa are the fronts of shops and of some private houses, &c.

Fig. 2 is a section through the house of Pansa from the street to the garden, showing the manner in which it is probable the roofs, &c., were arranged.

Fig. 3 is the probable elevation of the entrance front of this mansion, though the sketch (fig. 4) of part of the same in its present state shows how slight the evidence for it is.

Fig. 5 is an outline of the side of a room, with the ornaments, &c., with which it is decorated. This is an average specimen: many were much plainer, and some were more enriched.

Fig. 6 is the plan of an ordinary sized house in one of the private streets of Pompeii: the uses of the various parts may be generally gathered from those of the similar portions of the house of Pansa. The word Salve, printed across the threshold, is there wrought in mosaic.

Fig. 7 presents the presumed arrangement of the roofs, &c., of this house in section.

Fig. 8 is the elevation of it towards the street. This cannot really have been better than it appears here, and such must have been the ordinary average appearance of the street fronts of Pompeian houses. (*Vide* p. 471, *et seq.*)

Plate LXII. Fig. 1, an example to show how the term order is applied, and what parts of it the various technical terms are applied to, or are intended to indicate.

Figs. 2, 3, 4, 5, and 6, are the orders of the Italo-Vitruvian school as arranged by Palladio; fig. 2, the Tuscan; fig. 3, the Doric; fig. 4, the Ionic; fig. 5, the Corinthian; and fig. 6, the Composite. (*Vide* p. 477.)

Plate LXIII. Varieties of Italian composition from existing structures in Italy and elsewhere, in the Italian style.

Figs. 1, 2, 3, 4, and 5, are windows of various form and arrangement.

Figs. 6, 7, 8, and 9, are doors of various composition, with plans to show their arrangement and ichnographic projections, &c.

Figs. 10, 11, 12, and 13, are arches and arcades, rusticated and with columns, &c. The plans show their forms and ichnographic projections. (*Vide* p. 478, *et seq.*)

Plate LXIV. Front elevations alone of the fronts of St Paul's in London and St Peter's in Rome. These two structures exhibit many of the peculiarities of the ecclesiastical architecture of the Italian school. In this plate their comparative magnitude has not been attended to; they are drawn to different scales to bring them more nearly of the same size, so as to render the contrast more effective. (*Vide* p. 452 and 455.)

Plate LXV. Flank elevations of St Peter's and St Paul's, drawn to the same scale, to show their comparative magnitude, and to enable the reader to judge of their respective merits, as well as to elucidate observations which will be found in the text *passim*. (*Vide* p. 455, &c.)

Plate LXVI. Elevations of three esteemed Italian mansions. The merit of this (the principal) elevation of the Farnese Palace is divided between Antonio Sangallo and M. A. Buonarotti. The Villa Giula, near Rome, is esteemed one of the best works of Giacomo Barozzi da Vignolia; and the villa Capra near Vicenza, by Palladio, is, by the admirers of his style, considered the most perfect of his works. (*Vide* pp. 452, 455, 478, 479, &c.)

Plate LXVII. A series of arches in the Gothic and Pointed styles, from various structures in England. It exhibits the advance of the circular arch from the plainness exhibited in figs. 1 and 2, to the richer and more complicate arrangements of those examples which follow, until the ingrafting and gradual advance of the pointed arch. This first appears in fig. 10. Fig. 12 shows the substitution of the latter for the circular of fig. 9 in a similar composition. Fig. 13 exhibits the pointed arch on Gothic pillars or columns; and fig. 14 the perfected pointed arch with the clustered shafts which become identified with the Pointed style. (*Vide* p. 479, *et seq.*)

Plate LXVIII. The elevation of the south transept of Beverley Minster. This affords a perfect and beautiful example of external composition of the first period of Pointed architecture. The presence of the circular arch embracing the pointed arches of the doorway, and composing with others, shows how gradual the advance of the new style was; the upper part of the front showing also how completely it was already systematized when the circular arch was not yet quite discarded. The plan of this front shows the various ichnographic projections, and the arrangement of the clustered shafts of the doors and windows. Fig. 2 is a niche in front of, and fig. 3 a pinnacle to, one of the buttresses of the nave of the same edifice: these are of the second period. Figs. 4, 5, 6, 7, and 8, are windows from various edifices, showing the gradual advance from the plain lancet arch of the Beverley Minster transept to the arch the most elaborately enriched with tracery. Fig. 4 is but a modification of the composition of the doorways of fig. 1, as that is of figs. 9 and 12, Plate LXVII.; and the advance from that may be almost termed natural.

Plate LXIX. Fig. 1 is a sectional compartment of the nave of Lincoln Cathedral; it exhibits the mode of internal composition peculiar to the style of the first period; tending, however, to the transition, it will be observed, in many particulars, and as a comparison of it with the adjacent example, of the next period, will more clearly show.

Fig. 2 is a similar sectional compartment of the choir of Lincoln Cathedral; exemplifying the internal compo-

sition of the second period of the Pointed style; the plans of the shafts to both examples show their forms and arrangement. The subjects of the last three plates are drawn entirely, by his kind permission, from Mr Britton's *Chronological History of Ecclesiastical Architecture.*

Plate LXX., the front of York Minster, exemplifies the external composition of the second period, as that of Beverley Minster transept (Plate LXVIII. fig. 1) does that of the first period; and the difference will be rendered very clear by comparing them. The upper parts of the towers of the front of York Minster, however, it must be remembered (*vide* p. 482) are of the third period, and so is the central tower which appears in the distance between them.

The front of Pisa Cathedral is here introduced in contrast with that of York Minster, to show the striking difference which exists between the real Gothic achitecture of Italy and the Pointed style which superseded it so completely, in this country particularly, and to elucidate our observations to that effect at page 445 *et seq.* The cupola which appears behind and in the distance is surrounded at the base by pointed arches and pinnacles, all of which are evidently of much later date than the Gothic front.

Plate LXXI. Fig. 1 is an elevation of Westminster Hall. It exemplifies the style of external composition of the third period. It was selected because of the variety of matter it contains elucidatory of the period to which it belongs particularly, and of the Pointed style generally. The door, windows, and canopied tabernacles on the second story of the towers, are peculiar; the lower tabernacles, are more general, and the pinnacles, crockets, corbels, tablets, &c., may also be taken in exemplification of such things in the style generally.

Fig. 2 is a plan of the front, showing the ribs of the groined entrance, the ichnographic projections of the tabernacles, &c.

Fig. 3 is one of the flying buttresses of the flank of the edifice.

Fig. 4 is a spandrel of the entrance porch enlarged.

Fig. 5, crockets of the gable running from the towers to the crowning turret, enlarged.

Fig. 6, part of the head of one of the upper windows of the towers, enlarged.

Fig. 7, a foliated heraldic panel from under the pedestals of the lower tabernacles or niches of the front, enlarged.

Fig. 8, canopies and pinnacles, &c., of the lower tabernacles, enlarged; the buttresses on which they rest are also shown at large in intercepted lengths.

Fig. 9, an enriched foliated pendent of the foregoing example, marked *a*, at a still larger scale.

Fig. 10, one of the pedestals for the reception of statues within the niches or tabernacles, enlarged.

Fig. 11, part of one of the canopies, &c., of the tower tabernacles, enlarged.

Fig. 12, one of the foliated pendents, marked *b*, of the foregoing; and fig. 13 the corbel, marked *c*, of the same, on a still larger scale.

ARCHIVE, or ARCHIVES, a chamber or apartment wherein the records, charters, and other papers and evidences, of a state, house, or community are preserved, to be consulted occasionally. Thus, we say, the *archives* of a college, of a monastery, &c.

ARCHIVIST, or ARCHIVISTA, a keeper of an archive. Under the emperors the archivist was an officer of great dignity, held equal to the proconsuls, vested with the quality of a count, styled *clarissimus*, and exempted from all public offices and taxes. Among the ancient Greeks and Persians, the trust was committed to none but men of the first rank; among the Franks, the clergy, being the only men of letters, kept the office among themselves.

ARCHLUTE, or ARCILIUTO, a long and large lute, having its bass strings lengthened after the manner of the theorbo, and each row doubled, either with a little octave or a unison. It is used by the Italians for playing a thorough bass.

ARCHON (ἄρχων), in *Ancient History*, the title of the highest magistrates at Athens. On the death of Codrus, about B.C. 1100, royalty was abolished at Athens, apparently because the ancient and venerable title of king (βασιλεύς) made the chief magistrate too independent of the nobles or *eupatrids*. Accordingly, although the highest magistracy remained hereditary in the family of Codrus, and was held for life, it was thought expedient to change its title into *Archon*, which simply signifies "a ruler." In point of fact, however, the archon's power was equal to that of a king, except that he was responsible to the nobles. The first archon was Medon, and the office remained hereditary in his family, thirteen members of which successively held it for life, until, in the year B.C. 752, the duration of the archonship was limited to ten years. But 38 years later, the exclusive right of the family of the Medontids was abolished, and the archonship thrown open to all the eupatrids without distinction. This, however, did not satisfy the nobles, as only few of them had a chance of being ever raised to the highest magistracy; and in order to increase this chance, another reform was effected in B.C. 683, by which the highest magistracy was divided among nine archons, whose office lasted only one year. The executive, which thus remained in the hands of the nobles, was now attainable to a large number of them in the course of a few years. But the abuse of their prerogatives led to reforms by which the archonship was ultimately thrown open to all the Athenian citizens indiscriminately.

The first of the nine magistrates was simply called *the archon*, sometimes with the epithet *eponymus* (ἐπώνυμος), because the year was marked by his name, as it was at Rome by the names of the two consuls. At first this archon was at the head of the whole administration; but afterwards, during the period concerning which we have authentic information, and when democracy was fully developed, his functions appear to have been limited to the superintendence of the festivals of the Dionysia and Thargelia, and of the tragic choruses and certain sacrifices. All orphans were under his especial care; and he had, lastly, jurisdiction in all matters connected with the law of inheritance. His tribunal stood near the statues of the ten archegetæ or eponymic heroes, not far from the agora, or place of the popular assemblies. The second archon bore the title of *king* (βασιλεύς); for as his functions embraced everything connected with the public worship of the gods, it would have been an act of impiety to alter his title: he was the king of the state so far as religion was concerned, just as the *rex sacrorum* was at Rome. He, in conjunction with his wife (βασίλισσα), had to perform certain sacrifices on behalf of the state, and he was especially intrusted with the superintendence of the mysteries, the festival of the Lenæa, the torch-races, and gymnic contests. In all these matters the king-archon also had jurisdiction, and his court was in the stoa βασιλέως, near the agora. He had also to act the part of public prosecutor in all offences against religion, and against murderers whose case was judged by the Areopagus. But he himself had jurisdiction in disputes about the rights and duties of priests.

The third archon bore the title of *polemarchus* (πολέμαρχος), which indicates that originally he was the supreme commander of the Athenian forces; and in this capacity we find the polemarchus Callimachus at the head of the ten Athenian generals in the battle of Marathon, B.C. 490. But afterwards we no longer hear of the polemarchus as commander-in-chief; and his functions appear to have been limited to watching

over the rights and duties of the resident aliens, just as the archon eponymus watched over those of the citizens; and arranging the funeral games in honour of those who had fallen in battle, and similar other public solemnities. His office was near the Lyceum.

Each of these three archons was entitled to appoint two assessors or assistants (πάρεδροι), who, however, had to be sanctioned, after a previous scrutiny of their character and fitness, by the senate.

The six remaining archons were called *thesmothetæ* (θεσμοθέται), a name which is sometimes applied to the whole body of the archons. But the six formed a college of justice which had to take cognizance of all cases which did not belong to the jurisdiction of any other magistrate. They appointed the jury in the popular courts, and the days on which justice was administered. They had further to see that all new laws were duly entered, and annually to revise the laws to prevent contradictory enactments being maintained at the same time. They also superintended the voting in the popular assemblies, and ratified the treaties with foreign states. Their assessors were styled symbuli (σύμβουλοι).

From these accounts it is manifest that the functions of the archons were chiefly of a judicial nature; but the legislation of Draco, and still more that of Solon, produced considerable changes, for after the institution of the Ephetæ and the popular courts, the archons, generally speaking, acted only as presidents in the various courts. In some cases, lastly, the whole college of the archons formed a court by itself, *e.g.*, to pronounce the sentence of death against an exile returning to Athens contrary to law; to try magistrates deposed by the people; to conduct the elections of the ten generals and other military officers, and the like.

Until the time of Solon, the nobles alone were eligible to the archonship; his reforms threw open the office to all persons forming the highest property-class, whether they were eupatridæ or demotæ; and Aristides eventually opened up the highest magistracy to all Athenian citizens, without any qualification either of birth or of property. During the early or aristocratic period, the archons were elected, but when democracy attained its full development, they were chosen by lot; and to prevent the honour being thus conferred on unworthy persons, the newly-chosen archons had to submit to a double scrutiny, one before the senate, which was termed ἀνάκρισις, and a second in the agora, which was called δοκιμασία. At these scrutinies they had to prove that their ancestors for three generations had been real Athenian citizens, and every archon was obliged to promise on oath scrupulously to observe the laws of the state. During their year of office all the archons were exempt from liturgies or extraordinary burdens, and any person insulting them was branded with infamy. At the expiration of their office they had to render an account of the manner in which they had discharged its duties, and when they were found blameless they became members of the high court of the Areopagus. Even at the time when Greece had completely lost its political existence, the dignity of archon was sometimes an object of ambition with men of the highest rank, and the honour was sometimes even conferred upon, and accepted by, Roman emperors. (L. S.)

Archon is also applied by some authors to various officers, civil and religious, under the eastern or Greek empire.

ARCHPRIEST, or Archpresbyter, a priest or presbyter established in some dioceses with a pre-eminence over the rest. Anciently the archpriest was next in rank after the bishop; and acted in his absence as his vicar in all spiritual matters. In the sixth century there were several archpriests in the same diocese, from which period some believe them to have been called *deans*. In the ninth century there were two kinds of cures or parishes; the smaller governed by simple priests, and the baptismal churches by archpriests, who, besides the immediate concern of the cure, had the inspection of the other inferior priests, and gave an account of them to the bishop, who governed the chief or cathedral church in person. In the Greek church, archpresbyters still exist, who are invested with most of the functions and privileges of chorepiscopi or rural deans.

ARCHYTAS *of Tarentum*, a Pythagorean philosopher, eminently skilled in mathematics and geography. He flourished in the time of Plato (B.C. 400–365), and is said to have interposed his influence with Dionysius the Tyrant, in order to save the life of that philosopher. Iamblichus is evidently mistaken when he asserts that he was a hearer of Pythagoras; and the testimony of a writer mentioned by Photius would seem more worthy of credit, that he was the eighth successive preceptor of the Pythagorean school. So eminent were his military talents, that, in opposition to an express law of his country, that no man should be chosen more than once the general of its armies, he was elevated to that station no less than seven times. He taught that there is nothing so destructive to man as pleasure; that virtue is to be pursued for its own sake, and that every extreme is incompatible with it. Aristotle, according to some, was indebted to Archytas for his general heads of classification entitled the *Ten Categories*, but this opinion has little support beyond a verbal coincidence. The discovery of the duplication of the cube by means of the conic sections, and the method of finding two mean proportionals between two given lines is due to Archytas. He is also said to have invented several curious hydraulic machines, and his genius is honoured with the invention of the screw and crane. He perished in a shipwreck, and his body was found on the Apulian coast,—an occurrence commemorated in Horace's beautiful Ode, B. i. 28. An apocryphal treatise on the Categories, bearing his name, was published by J. Camerarius at Leipsic, 8vo, 1564. A complete collection of his Fragments was published by Orelli, Leipzig, 1821, 8vo.

ARCIS-SUR-AUBE, an arrondissement in the department of the Aube, in France, extending over 539 square miles, or 344,850 acres, and containing four cantons, ninety-three communes, and in 1851, 36,364 inhabitants. The capital of the arrondissement is of the same name, and contained 2606 inhabitants. It has manufactures of cotton and of hosiery, and a considerable trade in corn by the river Aube, on the left bank of which it is situated. Long. 4. 14. E. Lat. 48. 30. N. Near this place Napoleon, on the 20th March 1814, defeated a division of the allied forces. See France.

ARCO, a strong town and castle in the Tyrol, belonging to the house of Austria. It stands on the river Sarca, near the northern extremity of the lake of Garda. Pop. 2200. Long. 10. 48. E. Lat. 45. 52. N.

ARCOLE, a village of Austrian Italy, on the Alpone, 15 miles E.S.E. of Verona, with 1600 inhabitants. At this place Buonaparte gained a victory over the Austrians on 17th November 1796. See France, and Napoleon.

ARÇON, J. C. E. Le Michaud d', a French engineer and military writer of eminence, and memorable as the inventor of the floating batteries employed against Gibraltar, was born at Pontarlier in the year 1733. He was originally destined for the church; but, instead of employing himself in the studies suited to that profession, he became wholly engrossed with plans of fortifications, and was at length admitted, with the consent of his parents, into the corps of engineers. He distinguished himself at several sieges during the seven years' war; and had acquired so much reputation by his professional services and by his writings, that he was especially employed to assist in the last grand effort made by France and Spain for the reduction of Gibraltar in 1782. It was about this period that he projected the famous floating batteries; an invention which inspired the combined armies with the greatest hopes of success, and

at first occasioned no small alarm in the British garrison. Of the ultimate fate of these expensive and formidable engines all British readers must be sufficiently informed. Not one of the whole ten escaped destruction from the bombs and red-hot balls poured upon them from the garrison. M. d'Arçon, however, published a memoir to show that his batteries were wilfully exposed to destruction through the envy and jealousy which the contrivance had excited among the Spaniards; and this statement, whatever may have been its real value, seems to have obtained the general concurrence of his countrymen.

M. d'Arçon appeared in the capacity of a general in the first years of the Revolution; and, in particular, was employed in the invasion of Holland, where, in 1793, he besieged and took several fortified places. He soon afterwards withdrew or was driven from public life, and remained in retirement till 1799, when he was made a member of the Conservative Senate by Buonaparte. He died the following year, aged sixty-seven.

ARCOS DE LA FRONTERA, a Spanish town in the province of Cadiz, between Ronda and Santa Maria. It is situated on the banks of the river Guadalete, celebrated for that decisive battle of three days' continuance, near Xerès, by which the crown of the Gothic kings of Spain was transferred to the Arabian invaders. It contains two parish churches, seven monasteries, 1334 houses, and 12,000 inhabitants. Long. 5. 55. W. Lat. 36. 39. N.

ARCOT, a city of Hindustan, capital of a district of the same name, is situated on the S. side of the river Palar. Arcot is supposed to have been the capital of the Soræ, or the Soramundalum of Ptolemy, whence, by an easy derivation, Coromandel; but the present town is entirely of modern date. The Mogul armies, after they had captured Gingee, found the situation so unhealthy that they were forced to remove to the plains of Arcot, and began to build the present town about the year 1716. The nabob of Arcot, Anwanud Deen, being killed in battle in 1749, the place was taken by his competitor, who was supported by the French. In 1751 it was retaken by Colonel Clive, with 500 troops, from a garrison of 1100 men; and here that gallant soldier maintained himself for fifty days against the attacks of the French and their Indian allies, who were finally compelled to raise the siege. It was afterwards taken by the French, but was recaptured in 1760 by Colonel Coote, after the battle of Wandewash. Hyder Ali gained possession of it for a time after he had defeated the British under Colonel Baillie in 1780. Long. 79. 25. E. Lat. 12. 56. N.

ARCTIC, in *Astronomy*, an epithet given to the north pole, or the pole raised above our horizon. It is called the *arctic pole*, from the constellation of the little bear; called in Greek, ἄρκτος, the last star in the tail of which nearly points out the north pole.

ARCTIC *Circle* is a lesser circle of the sphere, parallel to the equator, and 23° 30′ distant from the north pole; from whence its name. This, and its opposite the *antarctic*, are called the two *polar circles*, and may be conceived to be described by the motion of the poles of the ecliptic round the poles of the equator, or of the world.

ARCTIC REGIONS. See POLAR REGIONS.

ARCTURUS, in *Astronomy*, a fixed star of the first magnitude, in the constellation Arctophylax, or Bootes. The word is formed of ἄρκτος, *bear*, and οὐρά, *tail*, *bear's tail*, in reference to its position.

ARCY, GROTTE D', a vast stalactitic cavern in the French department of Yonne, divided into many compartments, one of which is 1200 feet long, 85 feet high, and 40 feet wide.

ARCY, PATRICK D', member of the Academy of Sciences of Paris, a general officer in the French army, Chevalier of the order of St Louis, &c., was born in Ireland in 1725. His parents, in consequence of their attachment to the house of Stuart, left Ireland, and settled in France. He studied mathematics with distinguished success under Clairaut the elder, and had for his fellow-student the celebrated Clairaut the son. He obtained a commission in the French army, and in 1746 was embarked in the expedition which was intended to make a descent into Scotland. He was made prisoner, and was treated like other prisoners of war, no notice being taken of his having been born a British subject. He continued attached to the house of Stuart during the whole of his life.

In 1760 he published his *Essay on Artillery*. To estimate the force of the explosion of gunpowder, he employed a cannon suspended so that the arc of vibration described by it on its being fired was a measure of the force of explosion. To measure the initial velocity of a projectile, he used Robins's machine. Robins showed, that when the velocity of a projectile is great, the resistance opposed by the air is not in proportion to the square of the velocity, as is the case when the velocity is small. D'Arcy made experiments with a view of ascertaining this law, but without success. His work contains an account of experiments made by him to determine the most advantageous length of cannon. He published a paper on hydraulic machines in 1754, where he treats of the maximum of effect of water-wheels. He also published a paper concerning the duration of the impression of light on the retina. He found that the revolution of a luminous point must be rapid, so as to be performed in $\frac{8}{60}$ths of a second at the least, in order to produce the appearance of a continued luminous circle.

D'Arcy was of a handsome figure, and passed much of his time in the gay world. A short time before his death, he married a young lady, his niece, and took the title of Count. He died in 1779. (W. A. C.)

ARDEA, or ARDUA, a very ancient city of Latium, the capital of the Rutuli, on the river Numicus. It is now a village with 200 inhabitants, in the midst of pestilential swamps.

ARDEBIL, or ARDEBEEL, a town of Persia, in the province of Azerbijan, on a river which runs into the Aras or Araxes. It is situated on the southern side of the desert plain of Ardebil, which is 60 miles in length by 40 in breadth. The town contains about 500 or 600 families, and appears to have been built from some former city. It is surrounded by a ruinous wall of mud, flanked with towers in a like state of decay. It has a fort, which is a regular square, with bastions at the corners, fortified according to the European fashion. The only objects of interest are the tombs of Sheik Suffee, the ancestor of the Suffanean kings, and his descendants. It is still held in veneration as having been the residence of that prince.

ARDÈCHE, a department in the south of France, formerly Vivarais. The granitic chain of the Cevennes occupies a large part of it. The culminating point of that group is 5970 feet above the sea, and is named Mount Mezen. Sandstone forms the lower portions of the district, over which lie beds of a coal formation, limestone, and chalk; but the continuity of these beds is disturbed by the cones of extinct volcanoes, part of the remarkable belt that passes from Puy de Dôme, through Cantal and Haute Loire, towards the Rhone at Rochemaure. The surface = 2081 square miles; and the population, by the census of 1851, 386,505. The department contains three arrondissements; Tournon, Largentière, and Privas. Its chief rivers are the Rhone, Loire, Cance, Doux, Erieux, and Ardèche. The mineral products are iron, antimony, coal, &c. Wine, chesnuts, and olives, are abundant, but corn is rather deficient. The mulberry is much cultivated for the rearing of silkworms.

ARDEE, a town of Ireland, county of Louth, on the river Dee, whence its ancient name of Atherdee, "Town on the Dee." It was formerly a place of considerable importance, but now consists chiefly of miserable cabins. It has two old

castles, one of which is used as a court-house; a church of the thirteenth century; a large Roman Catholic chapel; savings bank; dispensary; and several schools. It has a considerable malt and corn trade. Pop. in 1851, 2752.

ARDELAN, a province of Persia, which forms the eastern division of Kurdistan. Its length is 200 miles, and its breadth about 160. It is divided from the plain of Hamadan by a small range of hills, and its western boundary is 100 miles beyond Senna, the capital, which is situated in Long. 40. E. and Lat. 35. 12. N., 60 miles from Hamadan. From the Sharook, which separates the province from Azerbijan, to Senna, the country presents either a succession of hills clustered and heaped together, or great table-lands covered with the flocks and tents of wandering shepherds, who pass the summer here, and migrate in the winter to the vicinity of Baghdad. The soil in the valleys or glens, which are narrow strips at the foot of the mountains, is fertile, and yields abundance of wheat and barley. The oil plant, *Sesamum orientale*, is everywhere cultivated, and also tobacco, though in small quantities. The deep valley in which the capital is situated is well cultivated, and interspersed with orchards of fruit-trees. The mountains to the west are covered with forests of oak, which produce fine timber, and abundance of gall-nuts, which are exported to India, while the oak is floated down the Tab into the Tigris. The inhabitants, and other pastoral and rude tribes, make little use of the natural advantages of the country, being addicted to war, cruelty, and rapine. There is another tribe of shepherds named Gheshkee, who are most expert and daring robbers. These tribes are under the government of a powerful chief, who pays an annual tribute to Persia, but is in all other respects independent. He rules over his vassals with the most absolute power, but is said to govern rather like a patriarch than a tyrant.—*Kinneir*.

ARDELL, James Mac, one of the ablest of mezzotinto engravers, is supposed to have been born in Ireland about 1711. His chief works are portraits of distinguished persons after Hogarth, Hudson, Reynolds, and others; and a few historical subjects after Vandyk, Murillo, and Rembrandt. He resided at London, and died there in 1765.

ARDEN, Arduen, or Ardven, the common name of forests among the Celts. It is written *Arduen* by Cæsar and Tacitus in speaking of the forest in Gaul.

ARDENNE, Forest of (the *Sylva Arduenna* of the Romans), an extensive woody and mountainous district in the north of France, stretching also into Belgium and the Grand Duchy of the Lower Rhine. It extends westward to the sources of the Somme, Oise, Sambre, and Scheldt, and eastward to the valley of the Moselle. In Cæsar's time it extended to the Rhine. Its average elevation is about 1700 feet: some of its peaks attain a height of 2500.

ARDENNES, a frontier department in the north-east of France, deriving its name from that of the celebrated forest. It is bounded on the north by Belgium; and on the west, south, and east, by the departments of Aisne, Marne, and Meuse, respectively. It is mostly mountainous, the northern part abounding with forests; and the climate is generally cold and humid. The only navigable rivers are the Meuse and Aisne, which are united by the canal of Ardennes. Of the tributaries of the Meuse in this department, the principal are the Chiers, Semoy, Bar, Vence, and Sermonne; those of the Aisne, the Aire, Vaux, and Retourne. Ardennes is celebrated for its sheep. Its woods abound in game, and its rivers in fish. Agriculture has recently made considerable progress in this department, nearly three-fourths of it being now under cultivation: the inhabitants are chiefly occupied in raising corn, and make but little wine. The country is rich in minerals, particularly in iron, lead, slate, and marble. The principal manufactures are cloths; iron, copper, and zinc goods; earthenware, glass, leather, and beer. It has an area of 517,385 hectares, or 1,278,530 acres; and is divided into five arrondissements, viz., Mezières, Rethel, Rocroy, Sedan, and Vouziers; comprehending 31 cantons and 478 communes. Pop. in 1851, 331,296. Its capital is Mezières.

ARDES, a town of France, in Lower Auvergne, and now in the department of Puy de Dôme. It serves as a mart for the trade between Upper and Lower Auvergne. Pop. 1773.

ARDFERT, a town of Ireland, in the county of Kerry, of which it was formerly the capital, though it is now a ruinous and decayed village. It had at one time a university, and was a bishop's see; but it is now united to that of Limerick. Here are several religious edifices. A pillar tower, which stood near the cathedral, and was one of the loftiest and finest in the kingdom, fell in 1780.

ARDGLASS, a seaport town of Ireland, county of Down, six miles south-east of Downpatrick, was formerly a place of considerable importance. Population in 1851, 974, chiefly engaged in the fisheries. It is much frequented by visitors during the bathing season. Vessels of 500 tons may enter the outer harbour at all tides, and its inner cove admits vessels of 100 tons. There is a lighthouse at the extremity of the pier in Lat. 54. 15. N. Long. 5. 36. W.

ARDISHEER, the founder of the Sassanian dynasty of Persia, called by the Romans Artaxerxes. See Persia.

ARDOCH, a parish in Perthshire, celebrated for a very perfect Roman camp, or large fort, with five ramparts and as many ditches, inclosing an area of 100 by 86 yards. See Gordon, *Itiner. Septent.*, Pennant's *Tour*, iii. 102. Adjoining, also, are remains of two Castra Æstiva, one of which is 953 by 650 yards, another 635 by 445 yards. General Roy considers these stations as the position of Agricola, before dividing his army into three bodies, when he marched against the Caledonii.

ARDOYE, a market-town of Belgium, in the province of West Flanders, and arrondissement of Roulers. Pop. in 1851, 6142.

ARDRAH, formerly an independent territory of Africa, on the slave coast of Guinea, but now a province of the kingdom of Dahomey. Its chief town, of the same name, is about forty miles inland, and has a population of 8000.

ARDRES, a town of France, in Pas de Calais. Here an interview took place between Francis I. and Henry VIII. king of England in 1520. It is eight miles south of Calais.

ARDROSSAN, a seaport town of Ayrshire, Scotland, situated on the Firth of Clyde opposite the island of Arran, and 16 miles north-west of Ayr. The town has lately been much improved, and is a favourite resort of visitors during the bathing season. Large sums were expended by the late Earl of Eglintoun in forming the harbour, which is sheltered by a pier and a small islet, and has a lighthouse with a fixed light on the north-east breakwater, in Lat. 55. 38. 27. N. Long. 4. 49. 28. W. It has a branch railway uniting it with the Glasgow and Ayr lines at Kilwinning, and communication by steamers with Arran, Belfast, and Liverpool. Pop. in 1851, 2071. See Ayrshire.

ARDSISCH, a town in the province of Wallachia, on a small river of the same name, which falls into the Danube. It was once the seat of government, but is fast decaying. It still contains six churches, a large and beautiful monastery, and the ruins of the ancient palace of the sovereigns.

ARE, the present French superficial measure, is a square, of which the sides = 10 metres. A metre = 39·37079 inches; and 100 ares or 1 hectare = 2·4711695 English acres; or 202½ hectares = 500 English acres.

AREA, in general, denotes any plain surface. The Latin word more properly denoted a threshing floor; and is derived from *arere* to be dry.

Area, in *Architecture*, denotes the space or site of ground on which an edifice stands. It is also used for inner courts and other inclosed spaces.

Area, in *Geometry*, denotes the superficial content of any figure. Thus, if a figure, *e. g.*, a field, be in form of a square, and its side be 40 feet long, its area is said to be 1600 square feet; or it contains 1600 little squares, each a foot every way.

AREBO, a considerable town of Benin, in Africa, on the river Formosa. Long. 5. 8. E. Lat. 5. 58. N.

ARECA, a genus of palms, two of which are remarkable. *A. oleracea* is the *cabbage palm* of the West Indies and Guyana, which attains a height of from one to two hundred feet, with a very slender stem, of only a few inches in diameter. It is felled to obtain the young shoots, which are eaten as a vegetable, especially in pickles; the nuts are sweet and edible, and the trunk forms excellent water-pipes, when its soft interior decays. *A. Catechu* is the well-known *Betel Palm* of India; the astringent kernels are universally chewed in the East, when mixed with the leaf of a sort of pepper and quick lime. This pepper is the *Piper Betle* of botanists. The nuts are also used to afford an inferior sort of catechu, named *Kassu*, and *Coury*, now seldom imported into Europe.

AREMBERG, a small market-town of Prussia, government of Coblenz, circle of Adenau, with 300 inhabitants. It is situated on the river Aar, and has a castle, the ancient residence of the dukes of Aremberg, who thence derived their title. About the year 1298, the earldom of Aremberg came by marriage to John of Engelbert, earl of Mark, in whose family it continued till 1547, when John of Barbançon, of the celebrated house of Ligne, by marrying the only daughter of the last earl, obtained possession of the lands. In 1572 it was raised to a principality, and ranked among the German States. In 1582, the prince obtained a seat in the diet; and Prince Philip Charles, who died in 1616, by marrying Ann of Croy obtained the possessions of the duke of Croy and Arschot. In 1644 Philip Francis, then the reigning prince, received the title of duke. By the peace of Luneville concluded in February 1801, between Austria, in the name of the German empire, and France, by which Belgium and the territory on the left bank of the Rhine were ceded to France, the duke lost the greater part of his possessions, and received as compensation the territories of Recklinghausen and Meppen. On the establishment of the confederation of the Rhine, the duke became a member of that body; but in 1810 he lost his sovereignty by Napoleon's incorporating his dukedom with France and the grand duchy of Berg, for which he received a rent of 240,702 francs, and remained in possession of his domains. In 1815 the duke received back his possessions, which, at the Congress of Vienna, were mediatized, a part to Prussia, and a part to Hanover. On account of the former, he became a peer of the Westphalian Estates; and, by the latter, a member of the House of Lords in Hanover. George IV., on 9th May 1826, elevated the duke's possessions in Hanover to a dukedom, under the title of Aremberg-Meppen. The present duke is also a grandee of Spain of the first class. His German possessions extend over about 780 geographical square miles, with 94,000 inhabitants; of which, 544 square miles, with 50,000 inhabitants, are in Hanover; besides which he has large estates in France, and extensive tracts of forest in the Pyrenees. The present duke resides at Brussels; and his income from all his estates is about 750,000 guilders, or L.62,500.

ARENA, in *Roman Antiquity*, the place where the gladiators fought; so called from its being strewed with sand, in order to conceal from the view of the spectators the blood spilt in the combat. Caligula, Nero, and others, are said to have strewed the arena with a golden dust (probably cinnabar) and with borax. An interesting description of the several games of the amphitheatre is given in the Eclogues of Calpurnius. (Edited by Glaeser, *Gotting*. 1842.)

ARENARIA, a genus of wading birds, to which our Redshank belongs.

Arenaria, a genus of plants of the natural order of Caryophylleæ, containing numerous species, of which ten are known in Britain, under the name of *sandworts*.

ARENARII, in *Antiquity*, gladiators who combated in the arena or amphitheatre.

ARENARIUM, in *Ecclesiastical Writers*, denotes a cemetery or burying-ground. The arenaria were properly a kind of pits or holes under ground, in which the ancient Christians not only buried their dead, but held their religious assemblies in times of persecution.

ARENDAL, a seaport town of Norway, on the Skagerrack, 35 miles north-east of Christiansand. Lat. 58. 27. N. Long. 8. 50. 25. E. It has a considerable shipping trade, particularly in iron and timber. Population, 3229, engaged in the distilleries, tobacco factories, dockyards, and in the iron mines around. The vicinity is remarkable for the number of beautiful and rare minerals found there.

ARENDT, Martin Frederic, a learned antiquary born at Altona in 1769. In 1798 he commenced his travels in pursuit of antiquarian lore, visiting the northern parts of Europe, and afterwards Spain, Italy, and Hungary. His peregrinations were performed entirely on foot; he frequently slept in the open air, and trusted for subsistence to the bounty of strangers. He made accurate observations on the antiquities of the countries through which he passed, and published a few memoirs; but much of his erudition, which was undoubtedly great, has perished with himself. A part of his papers and drawings were deposited in the library at Copenhagen. He died in prison at Naples in 1824.

ARENG, Labillardiere's designation of a genus of palms, known in Sprengel's work by the name of *Gomutus*, originally proposed for it by Rumphius. It contains only a single species, *G. saccharifer*. Its juice, when fermented, is palm wine, which is astringent and intoxicating. The trunk of this palm rises to the height of 25 or 30 feet, is covered with the coarse, black fibres, of which the Indians make cables; and from it a large quantity of farinaceous matter is obtained, which is manufactured into a species of sago. The sap as it flows from the plant is a pale, yellowish, transparent liquid, which is generally collected in gourds, or joints of the large bamboo tied to the cut midribs of the leaves. The plant is a native of Cochin-China and the Indian Isles.

ARENSBERG, or Arnsberg, a city of Westphalia, in Prussia, the chief town of a government and circle of the same name. It is situated on an eminence almost surrounded by the River Ruhr, 44 miles south-east of Munster, and 58 miles E.N.E. of Dusseldorf. It is the residence of the provincial authorities, and has a court of appeal, a catholic gymnasium, and a society of agriculture. Pop. 4438. Arensberg was the capital of the ancient Duchy of Westphalia, and was formerly a member of the Hanseatic league. Near the town are the ruins of an ancient castle, once the residence of the earls of Arnsberg; the last of whom, Gottfried, sold his earldom, in 1368, to the archbishop of Cologne.

ARENSBURG, a seaport town of European Russia, capital of the Island of Oesel in the Baltic, at the mouth of the Gulf of Riga. It is situated on the south side of the island, in Lat. 58. 15. N. Long. 22. 18. E. Pop. 1600. From the shallowness of its harbour, vessels are obliged to anchor in the roads, about five miles west of the town.

AREOLA, in *Anatomy*, the coloured circle surrounding the nipple of the breast.

AREOPAGUS, the highest tribunal at Athens, famous for the justice and impartiality of its decrees, to which the gods themselves are said to have submitted their differences. See Attica.

AREQUIPA, the most southern of the seven departments into which the republic of Peru is divided. It lies along the Pacific between Lat. 15. and 21. S. and Long. 69. and 75. W.; having on the north the departments of Lima,

Ayacucho, and Puno; and on the east and south, Bolivia. Its chief productions are silver, nitrate of soda, guano, sheep, alpaca wool, sugar, wine, and brandy. It is divided into seven provinces. The chief town of the department has the same name, and lies in the fertile valley of Quilca, 7775 feet above the level of the sea, in Lat. 16. 30. S. Long. 71. 48. W. This city is handsome and well built, with a cathedral, a college, a hospital, several nunneries and convents, and a bronze fountain in its great square. It has a very considerable trade, with manufactures of woollen and linen goods, and gold and silver ornaments. It is subject to frequent earthquakes; but the climate is mild and salubrious. Behind the city rise three lofty mountains, one of which, called the peak of *Misté*, is an active volcano, and rises to the height of 18,373 feet. Pop. 20,000.

ARES (Ἄρης), son of Zeus and Hera, the god of war among the Greeks, identified by the Romans with their own Mars. From this word was derived ἀρετή, *virtue*, as also ἀρείων, ἄριστος, &c., the earliest idea of excellence being connected with martial superiority.

ARETÆUS *of Cappadocia*, a Greek physician of the sect of the Pneumatists, who, according to some, lived in the reign of Augustus; according to others, under Trajan or Hadrian. He wrote, in the Ionian dialect, several treatises on acute diseases and other medical subjects, some of which are still extant. The best edition of his works is that of Boerhaave, in Greek and Latin, with notes, printed in 1731; that printed at Oxford in 1723, in folio, is also much esteemed: and an excellent edition by C. G. Kühn, was published at Leipzig in 1828.

ARETALOGI, in *Antiquity*, a class of philosophers, chiefly of the Cynic or Stoic school, who frequented the tables of great men, and entertained them at their banquets with disputations on virtue, vice, and other popular topics. These are sometimes also denominated *Circulatores Philosophi.* Such a mode of life would naturally degenerate into that of the parasite and buffoon; hence they are mentioned with contempt by Juvenal, *Sat.* xv.

ARETHUSA, a celebrated fountain near the city of Syracuse, in Sicily, famous for the quantity of its waters, and the number of fishes it contained. Many fables were invented by the ancients concerning this fountain. It was said to have derived its name from Arethusa, the daughter of Nereus and Doris, and the companion of Artemis (Diana), who changed her into a fountain to deliver her from the pursuit of her lover Alpheus. It was also believed that the river Alpheus ran under or through the waters of the sea, without mixing with them, from Peloponnesus to Sicily. Mr Brydone informs us that it still continues to send forth an immense quantity of water, rising at once to the size of a river, but is entirely abandoned by the fishes it formerly contained in such plenty. Mr Swinburne describes this once famous fountain as a large pool of water near the quay, defended from the sea by a wall, and almost hidden by houses on every other side. The water is not salt but brackish, and fit for no purpose but washing linen. "Such," says he, "is the celebrated fountain of Arethusa, whose soft, poetical name is known to every reader."

ARETINO, GUIDO, famous for his improvements in music, lived in the eleventh century. He was born in the city of Arezzo, in Tuscany; and having been taught the practice of music in his youth, and being probably retained as a chorister in the service of the Benedictine monastery founded in that city, he became a monk professed, and a brother of the order of St Benedict.

In this retirement he seems to have devoted himself to the study of music, particularly the system of the ancients, and, above all, to reform their method of notation. The difficulties that attended the instruction of youth in the church offices were so great, that, as he himself says, ten years were generally consumed barely in acquiring the knowledge of the plain song; and this consideration induced him to labour after some amendment,—some method that might facilitate instruction, and enable those employed in the choral office to perform the duties of it in a correct and decent manner. Were we to credit those legendary accounts that are extant in old monkish manuscripts, we should believe he was assisted in his pious intention by immediate communications from heaven. Some speak of the invention of the syllables as the effect of inspiration; and Guido himself seems to have been of the same opinion, by his saying it was revealed to him by the Lord, or, as some interpret his words, in a dream. Graver historians say, that being at vespers in the chapel of his monastery, it happened that one of the offices appointed for that day was the hymn to St John,—

UT queant laxis   *REsonare fibris*
MIra gestorum   *FAmuli tuorum*
SOLve polluti   *LAbii reatum,*
Sancte Joannes!

During the performance of the hymn, he remarked the iteration of the words, and the frequent returns of UT, RE, MI, FA, SOL, LA. He observed likewise a dissimilarity between the closeness of the syllable MI and broad open sound of FA, which, he thought, could not fail to impress upon the mind a lasting idea of their congruity; and immediately conceived a thought of applying these six syllables to perfect an improvement either then actually made by him, or under consideration, viz., that of converting the ancient tetrachords into hexachords.

Struck with the discovery, he retired to his study, and having perfected his system, began to introduce it into practice. The persons to whom he communicated it were the brethren of his own monastery, from whom it met with but a cold reception, which he ascribed to envy. However, his interest with the abbot, and his employment in the chapel, gave him an opportunity of trying the efficacy of his method on the boys who were training up for the choral service, and it exceeded the most sanguine expectation. "To the admiration of all," says Cardinal Baronius, "a boy thereby learnt, in a few months, what no man, though of great ingenuity, could hitherto acquire in several years."

The fame of Guido's invention soon spread abroad, and his method of instruction was adopted by the clergy of other countries. We are told by Kircher, that Hermannus bishop of Hamburgh, and Elviricus bishop of Osnaburg, made use of it; and by the authors of the *Histoire Littéraire de la France*, that it was received in that country, and taught in all the monasteries in the kingdom. It is certain that the reputation of his great skill in music had excited in the pope a desire to see and converse with him; of which, and of his going to Rome for that purpose, and the reception he met with from the pontiff, he himself has given a circumstantial account in the epistle hereafter mentioned.

It seems that John XX., or, as some writers compute, the nineteenth pope of that name, having heard of the fame of Guido's school, and conceiving a desire to see him, sent three messengers to invite him to Rome. Upon their arrival, it was resolved by the brethren of the monastery that he should go thither attended by Grimaldo the abbot, and Peter the chief of the canons of the church of Arezzo. Arriving at Rome, he was presented to the holy father, who received him with great kindness, and honoured him with several interviews, during which he interrogated him as to his knowledge in music; and upon sight of an antiphonary which Guido had brought with him, marked with the syllables according to his new invention, the pontiff looked upon it as a kind of prodigy, and ruminating on the doctrines delivered by Guido, would not stir from his seat till he had learned perfectly to sing off a verse; upon which he declared that he could not have believed the efficacy of the method,

if he had not been convinced by the experiment he had himself made of it. The pope would have detained him at Rome; but labouring under a bodily disorder, and fearing an injury to his health from the air of the place, and the heats of the summer, which was then approaching, Guido left that city upon a promise to revisit it, and explain to his holiness the principles of his new system.

On his return home he visited the abbot of Pomposa, a town in the duchy of Ferrara, at whose request he took up his abode in the monastery. Here he composed a tract on music, entitled *Micrologus*, i. e., a short discourse, which he dedicated to Theobald, bishop of Arezzo; and finished, as he himself at the end of it tells us, under the pontificate of John XX., and in the 34th year of his age. Vossius speaks also of another musical treatise written by him, and dedicated to the same person. Most of the authors who have taken occasion to mention Guido, speak of the Micrologus as containing the sum of his doctrine; but it is in a small tract, entitled *Argumentum novi Cantus inveniendi*, that his declaration of his use of the syllables, with their several mutations, and in short his whole doctrine of solmization, is to be found. This tract forms part of an epistle to a very dear and intimate friend of Guido, whom he addresses thus, "Beatissimo atque dulcissimo fratri Michaeli," at whose request the tract itself seems to have been composed.

Whether Guido was the author of any other tracts is not easy to determine. It nowhere appears that any of his works were ever printed, except that Baronius, in his *Annales Ecclesiastici*, tom. xi. p. 73, has given at length the epistle from him to his friend Michael of Pomposa, and that to Theobald, bishop of Arezzo, prefixed to the Micrologus; and yet the writers on music speak of the Micrologus as of a book in the hands of every one. Martini cites several manuscripts of Guido; namely, two in the Ambrosian library at Milan, the one written about the twelfth century, the other less ancient; another among the archives of the chapter of Pistoja, a city in Tuscany; and a third in the Medico-Laurenziano library at Florence, of the fifteenth century: these are clearly the Micrologus. Of the epistle to Michael of Pomposa, together with the *Argumentum novi Cantus inveniendi*, he mentions only one, which, he says, is somewhere at Ratisbon. Of the several tracts above mentioned, the last excepted, a manuscript is extant in the library of Baliol College, Oxford. (See Kiesewetter *Hist. of Music;* translated by Robert Müller: London, 1848, chap. ii.)

Aretino, *Leonardo*, one of the most learned men of the fifteenth century, was secretary to the republic of Florence, and translated from the Greek into Latin some of the Lives of Plutarch, and Aristotle's Ethics. He also composed three books of the Punic war, as a supplement to those wanting in Livy; the history of the transactions in Italy during his time; that of ancient Greece; that of the Goths; that of the republic of Florence; and many other works. He died in 1443, aged 74.

Aretino, *Francesco*, a man of great learning, and well acquainted with the Greek language. He translated into Latin the Commentaries of St Chrysostom upon St John, and about twenty homilies of the same father; he also translated the Letters of Phalaris into Latin, and wrote a treatise *De Balneis Puteolanis*. He studied at Sienna about the year 1443, and afterwards taught law there with such reputation that he was called the *Prince of Subtleties*. He taught also in the university of Pisa, and in that of Ferrara.

Aretino, *Pietro*, a native of Arezzo, who lived in the sixteenth century. He was famous for his satirical writings; and was so bold as to direct his invectives even against sovereigns, and from thence got the title of the *Scourge of Princes*. Francis I., the Emperor Charles V., most of the princes of Italy, several cardinals, and many noblemen, courted his friendship by presents, either because they liked his compositions, or perhaps from an apprehension of falling under the lash of his satire. Aretino became so insolent, that he is said to have got a medal struck, on one side of which he is represented, with these words, *Il divino Aretino;* and on the reverse, sitting upon a throne, receiving the presents of princes, with these words, *I principi tributati da popoli, tributano il servidor loro*. Some imagine that he gave himself the title of *Divine*, signifying thereby that he performed the functions of a god upon earth, by the thunderbolts with which he struck the heads of the highest personages. He used to boast that his lampoons did more service to the world than sermons; and it was said of him, that he had subjected more princes by his pen than the greatest had ever done by their arms. Aretino wrote many irreligious and obscene pieces; such are his dialogues, called *Ragionamenti*. There is likewise imputed to him another very obscene performance, *De omnibus Veneris schematibus*. "It was about the year 1525 (says M. Chevillier, *Origine de l'Imprimerie de Paris*, p. 224) that Julio Romano, the most famous painter of Italy, instigated by the enemy of the salvation of mankind, invented drawings for 20 engraved plates; the subjects are so immodest that I dare only name them. Pietro Aretino composed sonnets for each figure. George Vasari, who relates this in his *Lives of Painters*, says he does not know which would be the greatest impurity, to cast one's eyes upon the drawings of Julio, or to dip into the verses of Aretino." Some say that Aretino changed his libertine principles; but however this may be, it is certain that he composed several theological or pious pieces. He wrote a paraphrase on the penitential psalms, and another on Genesis; the Life of the Virgin Mary, and that of St Catharine of Sienna, and of St Thomas Aquinas. His familiar Letters were collected and published at Paris, in 6 vols. 8vo, 1609. He was author likewise of various poetical pieces, among which is a tragedy on the subject of the Horatii, possessed of considerable merit. He died in the year 1556, at the age of 65.

AREZZO (the ancient *Arretium, Arretinus*, or *Aretinus*), a city of Tuscany, capital of a province of the same name, situated on the Chiano, an affluent of the Arno, 40 miles south-east of Florence. Lat. 43. 18. 6. N. Long. 11. 53. 35. E. It is the seat of a bishop and of a court of appeal; and has a magnificent cathedral of the thirteenth century with some fine monuments, many churches and cloisters, several educational institutions, a surgical school, hospital, library, and museum. In the principal square stands a magnificent building called Le Loggie, containing the custom-house, the theatre, town-hall, &c., with a portico 400 feet in length. Its principal manufactures are woollen stuffs and pins. Pop. 9500. Arezzo is the birthplace of many eminent persons, among whom were Mæcenas, Petrarch, Vasari, Bracci, Leonard Bruin, called Aretin, Guido the great improver of musical notation, and the naturalist Redi.

Arretium was one of the most ancient and powerful of the Etruscan cities. History is silent as to the period when it became subject to the Roman sway; but after the conquest of Italy, Arretium was a military post of the highest importance to the Romans, as commanding the western entrance into Etruria, and the valley of the Tiber from Cisalpine Gaul; and here Flaminius was posted with his army to oppose the advance of Hannibal in the second Punic war. On the commencement of the civil war in B.C. 49, this was one of the first places that Cæsar occupied after crossing the Rubicon. The only ancient remains in Arezzo are some small portions of a Roman amphitheatre; and hence some suppose that the modern city occupies the site of the Roman Arretium, but that the ancient Etruscan city of that name was distant two or three miles to the south-east, where some remains of what are called cyclopean walls are still visible. Many valuable relics of antiquity have been found at Arezzo, among which are numerous works in bronze, especially the

Chimæra and the statue of Minerva, which are now preserved in the gallery at Florence.

Pliny informs us that its pottery was celebrated; and many specimens have been found there of a peculiar red ware figured in relief, wholly different from the painted vases of southern Etruria and Campania.

ARFE, HENRIQUE, and JUAN DE, two celebrated artists in silver of the times of the Emperor Charles V., and King Philip II. of Spain. The magnificent *custodia* or tabernacle for the host, on the altars of several of the Spanish cathedrals, as at Sevilla, Cordova, and Toledo, &c., are by them. The designs are architectural, with many well-engraved figures, and an idea may be formed of their size, from their each consisting of from six to eight cwt. of pure silver. The first artist was grandfather of the second.

ARGAND, AIMÉ, a Genevese, who, about 1782, invented the lamp known by his name. It has a hollow wick, so as to admit air to both surfaces of the flame, by which the heat and light are much increased. Until the coal-gas lamp was known, the argand lamp was much used by chemists, and also for illuminating houses. It has also been employed in gas-burners, but consumes much gas.

ARGAUM, in Southern India, a village of Hyderabad, or the territory of the Nizam This place is celebrated for the battle fought on the 28th November 1803, between the combined forces of Scindia and the Rajah of Berar, and the British army under the command of Major General Wellesley (afterwards Duke of Wellington), in which the Mahrattas were defeated with great loss. A medal struck in England in 1851 commemorates the victory. Distant south-west from Ellichpoor 40 miles, north-east from Aurungabad 135. Lat. 21. 2. Long. 77. 2. (E. T.)

ARGEI, or ARGÆI, in *Roman Antiquity*, thirty human figures made of rushes thrown annually by the priests or vestals into the Tiber on the day of the ides of May. According to Dionysius of Halicarnassus, this custom was instituted to satisfy the scruples of the people when human sacrifices to Saturn were abolished by Hercules. (*Antiq. Rom.* i. 19, 38.)

ARGELES, an arrondissement in the department of the Upper Pyrenees, in France, extending over 523 square miles, or 334,698 acres. It is divided into five cantons, and subdivided into 99 communes. Pop. in 1851, 42,558. The chief city of the arrondissement, of the same name, is situated in the beautiful valley of Lavedan, on the banks of the Gave d'Azun.

ARGENSOLA, BARTOLOME LEONARD DE, a native of Barbastro in Aragon, born in 1566. He studied at the university of Huesca, embraced the ecclesiastical profession, and became chaplain to Doña Maria of Austria. He was the continuator of the *Anales de Aragon* of Zurita, the author of a history of the conquest of the Molucca Isles, besides some poetical effusions, all which are commended by Bouterwek for elegance and correct purity of style. His elder brother, Lupercio, was secretary to the Conde de Lemos, when viceroy of Naples, and left behind him poetic works of merit not yet published. (Bouterwek, *Geschichte.*)

ARGENT, the common French word for *silver.* It is used in heraldry to signify purity, beauty, and gentleness.

ARGENTAC, or ARGENTAT, a town of France, in the department of Correze, on the river Dordogne. Pop. 2076. In the vicinity are mines of coal and lead.

ARGENTAN, an arrondissement in the department of the Orne, in France, extending over 729 square miles, or 466,690 acres. It comprehends 11 cantons, divided into 190 communes. Population in 1851, 106,854. The chief city of the arrondissement is of the same name. It is situated on an elevation in a beautiful plain, through which the Orne runs. It contains 5425 inhabitants, who manufacture thread-lace of a fine quality, some linen goods, and leather. Long. 0. 2. W. Lat. 48. 44. N.

ARGENTARIUS is frequently used in Roman Wr[illegible]rs for a money changer or banker. The argentarii were capitalists, who made a profit either by the changing or lending of money at interest. They had their *tabernæ* or offices. in the *forum Romanum*, built there as early as the reign of L. Tarquinius Priscus.

ARGENTEUIL, a small town of France, in the department of Seine and Oise, and capital of a canton. It stands on the Seine, 11 miles north-east of Versailles. Pop. 4569. It was to a nunnery in this town that Heloise retired after the misfortune of Abelard. See ABELARD.

ARGENTIERE, or CIMOLI, the ancient Κίμωλις, one of the Cyclades, is about 18 miles in compass, and very mountainous. Pop. 800. The *Cimolia terra* of antiquity is still found here, and is formed into cakes, which are stamped with the seal of the Grand Seignior. See CIMOLIA TERRA.

ARGENTINE CONFEDERATION. See PLATA, LA.

ARGENTINUS, a deity worshipped by the Romans as the god of silver coin; as Æsculanus, whom they made his father, was the god of brass money, which was in use before silver.

ARGENTUM ALBUM, in our old customs, silver coin, or pieces of bullion, that passed for money.

ARGENTUM *Dei, God's penny*, anciently signified earnest money, or money given to bind a bargain; in some places called *erles* or *arles*, and by the civilians and canonists *arrhæ.*

ARGO, in *Antiquity*, the ship celebrated in ancient poetry as that in which the Argonauts made their expedition to Colchis in quest of the golden fleece. Jason having happily accomplished his enterprise, consecrated the ship Argo to Poseidon (Neptune), or, as others say, to Athena (Minerva), on the isthmus of Corinth, where, they add, it did not remain long before it was translated into heaven, and made a constellation.

ARGOBAST, LOUIS FRANÇOIS ANTOINE, a distinguished French analyst, born in 1759 at Mutzig in Alsace. He was professor of mathematics at Straasbourg, and author of the *Traité du Calcul des Dérivations*, a work of great merit. This amiable man died on the 8th April 1803.

ARGOL, or ARGAL, the commercial name for crude tartar, which encrusts the sides of vessels in which wine has been kept. It is much used in dyeing to dispose the stuffs to take their colours the better.

ARGONAUTS, the name given to Jason and his companions who, to the number of fifty, embarked in the ship Argo. "The designs of the Argonauts," says Dr Gillies, in his *History of Greece*, "are veiled under the allegorical, or at least doubtful phrase of *carrying off the golden fleece;* which, though easily explained, if we admit the report that the inhabitants of the eastern banks of the Euxine extended fleeces of wool in order to collect the golden particles which were carried down by the torrents from Mount Caucasus, is yet described in such various language by ancient writers, that almost every modern who examines the subject thinks himself entitled to offer, by way of explanation, some new conjecture of his own. But in opposition to the most approved of these conjectures, we may venture to affirm that the voyage to Colchis was not undertaken with a view to establish extensive plans of commerce, or to search for mines of gold, far less to learn the imaginary art of converting other substances into that precious metal; all such motives supposing a degree of speculation and refinement unknown in that age to the gallant but uninstructed youth of Thessaly. The real object of the expedition may be discovered by its consequences. The Argonauts fought, conquered, and plundered; they settled a colony on the shores of the Euxine, and carried into Greece a daughter of the king of Colchis, the celebrated Medea, whose crimes and enchantments are con-

demned to eternal infamy in the immortal lines of Euripides."

ARGONAUTS *of St Nicholas* was the name of a military order instituted by Charles III., king of Naples, in the year 1382, for the advancement of navigation, or, as some say, merely for preserving amity among the nobles. They wore a collar of shells inclosed in a silver crescent, from which hung a ship with this device, *Non credo tempori*, I do not trust time. Hence these Argonaut knights came to be called *knights of the shell.* They received the order of St Basil, archbishop of Naples, and held their assemblies in the church of St Nicholas their patron.

ARGONNE, the old name of a district in France, now included in the departments of Marne, Meuse, and Ardennes. It may be described as a vast forest interspersed with a few towns and villages, and hence called the Forest of Argonne.

ARGOS, an ancient name of Peloponnesus, from Argos, one of the kings. Strabo derives the name from a Thessalian word signifying a plain.

Several ancient cities bore the name of Argos, particularly the capital of Argolis or ARGEIA. Argos was originally the seat of nine petty sovereigns of the family of the Inachides, the last of whom was expelled by Danaüs, whose descendants were termed Belides. Agamemnon was king of Argos during the Trojan war: but 80 years afterwards, his descendants were deposed by the Heraclidæ; and Argos assumed a republican form of government, which it retained until the dissolution of the Achæan league. The character of this state contrasts unfavourably with some other of the Grecian republics. It tyrannized over Mycenæ, which it destroyed 568 years B.C.: it did not join the Greek confederacy against Persia, and was constantly opposed to Sparta. The great deity of the city was Hera, or Juno, who had a grand temple there, existing in the time of Pausanias.

Argos was founded by Pelasgians; and remains of the ancient architecture, commonly called Cyclopean, in a fine state of preservation, may still be seen in its acropolis, on the hill of Larissa, and its spur Deiras. The summit of these eminences is crowned by the ruins of a castle, of the times of the Lower Empire, but it has antique substructions. The only other remains of antiquity at modern Argos are inscriptions, fragments of sculpture, and architecture, scattered in the plain, and among the present houses. Argos, as it was, is described in *Pausanias;* as it is, in Col. Leake's *Travels*, vol. ii.; and Dodwell's *Pelasgic Remains.*

The modern Argos is 5 miles north-west of Napoli di Romania, in Lat. 37. 40. N. Long. 22. 44. E. It contains about 8000 inhabitants.

ARGOS, surnamed *Amphilochicum* to distinguish it from the preceding, was the capital of the territory of the Amphilochians. It stood at the eastern extremity of the Ambracian Gulf. When Augustus, after the battle of Actium, founded Nicopolis, he removed the inhabitants of Argos to that city. The modern village of *Neokhori* is supposed by Col. Leake to occupy the site of this city.

ARGOSTOLI, a seaport town, capital of Cephalonia, one of the Ionian islands. The town has lately been much improved, and has a quay a mile in length, and a fine bridge. Pop. 5000. Lat. 38. 10. 40. N. Long. 19. 59. 3. E.

ARGUIN, a small island in a bay of the same name, situated on the western coast of Africa, near the southern termination of the Great Desert. Major Rennell supposes it to be the island to which the ancients, and particularly Hanno, gave the name of Cerne. The Portuguese early formed a settlement there, and even made it for some time the principal point from which they attempted to penetrate into the interior; but the extensive deserts by which it was bordered were very unfavourable for this object, and the banks of the Senegal have been found more advantageous in every respect. The shores round Arguin, however, abound with valuable turtle, and the sea affords a considerable supply of stock fish. Long. 16. 20. W. Lat. 20. 23. N.

ARGUMENTUM AD HOMINEM, is that form of argument which presses a person with the consequences drawn from his own principles, concessions, or conduct.

ARGUN, ARGAN, or ERGON, a river of Tartary, in the country of the Mongols, which rises from a lake called Dalai, or Koulon-nor, situated in Long. 119. 14. E. and Lat. 49. N. It is considered to be the original source of the Amur, and forms the boundary between the Chinese and Russian empires.

ARGUNSKOI, a town and fortress of Siberia, in the government of Irkutsk, on the west bank of the river Argun, 162 miles from its mouth.

ARGUS, in *Fabulous History*, was the son of Arestor, and had 100 eyes, 50 of which were always open. Hera made choice of him to guard Io, whom Zeus had transformed into a white heifer; but Zeus, pitying Io for being so closely confined, sent Hermes, who with his flute charmed Argus to sleep, sealed up his eyes with his caduceus, and then cut off his head. Hera, to reward his fidelity, transplanted his eyes into the tail of the peacock, a bird which was sacred to her divinity.

ARGUS-SHELL, a species of porcelain shell, beautifully variegated with spots, resembling in some measure those in a peacock's tail.

ARGUTIÆ, witty and acute sayings, which commonly signify something further than the mere words at first sight seem to import.

ARGYLESHIRE, or ARGYLLSHIRE, a county on the western coast of Scotland, comprehending not only an extensive district on the mainland, but also a number of the Hebrides or Western Isles.

The mainland lies between Lat. 55. 15. and 56. 55. N., and between Long. 4. 32. and 6. 6. W.; and its greatest length from the Mull of Cantire to Lochiel is 115 miles, with a breadth of about 66 miles. It is bounded on the north by Inverness-shire, east by the counties of Perth and Dumbarton and the Firth of Clyde, south by the Irish Sea, and on the west by the Atlantic Ocean. From the windings of the numerous bays and creeks with which the land is everywhere indented, it is supposed to have more than 600 miles of sea-coast. This part of the county contains 2260 square miles, or 1,446,400 acres.

The islands of Argyleshire belong to the HEBRIDES; and a more particular account of them will be found in that article. See also ISLAY, MULL, JURA, &c. The islands have a superficial area of 950 square miles, or 608,000 acres.

The entire country thus contains 3210 square miles, or 2,054,400 acres, of which only about 165,000 acres are cultivated. It is divided into six districts, viz., Argyle, Cowal, Kintyre, and Knapdale, Lorn, Mull, and Islay; and contains 51 parishes, and parts of two others.

The general features of the county are varied, and striking in a high degree, consisting of lofty mountains, deep glens, and inlets of the sea entering far into the land. Towards the northern parts it assumes the wild and savage grandeur so peculiarly characteristic of the Highlands of Scotland. Mountains piled on mountains in magnificent disorder present a sublime, but, in an agricultural point of view, a very unpromising aspect. Some of the mountains are among the loftiest is Scotland; as Ben Cruachan, near Loch Awe (3669 feet), Benmore, in Mull (3168), Cruach-Lussa (3000). The inlets of the sea are very numerous; the principal of which are Loch Fyne, Loch Linnhe, Loch Etive, Loch Sunart, Loch Leven, &c. The district of Kintyre enters into the North Channel, and is almost divided from the mainland at the narrow isthmus of Tarbet. The district of Cowal is also nearly peninsulated by Loch Long on the one side, and Loch Fyne on the other. The interior of the county is in-

terspersed with a number of lakes, the principal of which is Loch Awe.—(See AWE.) The total area of fresh-water lakes in Argyleshire is about 52,000 acres. The rivers, as might be expected from the nature of the country, are all short and rapid.

The mainland is chiefly composed of primary strata, consisting of gneiss, mica-slate, often containing chlorite and talc-slate, quartz rock, and in some places clay-slate, and red sandstone. The districts of Kintyre, Knapdale, Cowal, Glenorchy, and the eastern part of Lorn, present the five first-mentioned, almost everywhere, until they meet the granite on the northern side of Loch Etive, and the trap formations of Western Lorn. These primary strata reappear in Appin, and then they give place to clay-slate, which is extensively quarried at Balachulish. Those primary rocks also form a part of Sunart and Morven. Gneiss and mica-slate are the general rocks on both sides of Loch Fyne; and at the ferry of St Catherine, opposite to Inverary, is the quarry of chlorite-slate of which the ducal castle is built.

Gneiss, mica-slate. and quartz-rock, are the principal strata of the isles of Coll and Tirey, Colonsay, Oransay, and of Iona; they are found also alternating with the clay-slate which constitutes the greatest part of Islay, Scarba, and Jura. The remarkable summits known as the *paps* of Jura, consist of very regularly stratified quartz-rock, which, indeed, is the fundamental rock of that island.

Granite, except in veins, is rather rare in Argyle. A considerable extent of this rock exists to the north and north-east of Loch Etive; and at the south-west of Mull, the extreme end of the promontory of Ross, is a granitic mass that seems to extend to the adjacent island of Iona. This granite is hard and compact, well suited for building, and has been quarried for the magnificent lighthouse erected on the Skerry Vohr. Gneiss, mica-slate, and quartz-rock, rest on the eastern side of the granite, and are interposed between it and the trap formations of the island.

Clay-slate forms a large portion of some of the islands of this county. A very durable and fissile species of this rock has long been quarried in some of what have been locally denominated the *Slate Islands*. The western side of Lunga consists of quartz-rock; but on its eastern side is found a fine roofing slate, similar in quality to that long wrought in the small isle called Easdale, with which a great many houses in Scotland are covered. These slates always contain bright, hard crystals of iron pyrites. Luing, Seil, and Torosa, also afford roofing slate, and a coarser sort that forms a good paving flag, which seems associated with greywacke.

Trap rocks form no inconsiderable part of this county. They occupy a wide district on the west side of Lorn, from Milford Loch, stretching northward beyond the entrance of Loch Etive, as far as Loch Creran. There they generally appear as greenstone and trap-tuffa. They constitute about nine-tenths of Mull. The western part of Ardnamurchan and Morven, on the north side of Mull Sound, are also of trap formations; as are the islands of Kerrera, Ulva, Gometra, the Treshnish group, and the beautiful columnar cliffs and caves of Staffa. To the same formation we must refer the more distant isles of Canna, Muck, and Eig; but on the two former there seem to exist small vestiges of a lias limestone, to which those green isles are probably indebted for their fertility. Eig, if it be allowed to notice it here, consists of a huge bed of trap, through which the singular porphyritic mass of the *Scur* abruptly projects to the height of 470 feet. In the trap-tuffa of Canna, fragments of lignite or brown coal are found. The rocks of the more considerable island of Rum are strata of quartz rock and red sandstone, traversed by numerous veins of basalt, in which most beautiful masses of heliotrope occasionally occur. The trap in many places also affords beautiful specimens of stilbite, mezotype, and other zeolites. They all affect more or less the magnetic needle, especially that of the *Compasshill* in Canna. In the trap-tuffa at Ardtunhead in Mull, the Duke of Argyle, in 1850, discovered, alternating with basalt beds, three beds containing petrified leaves of plants. This tuffa resembles much the *lava ashes* of Auvergne.

Limestone is not an abundant product of Argyle. Considerable strata of a bluish limestone, however, alternate with clay-slate in the central parts of Islay; and this valuable stone forms the upper stratum of the long island of Lismore. A white hard dolomite occurs as a bed in the primitive strata on the south side of Iona. It takes a good polish, and is variegated with specks of noble serpentine and indurated stealite. In Tirey, a flesh-coloured marble, spotted with dark green hornblende, occurs in small quantity in gneiss. Argyle is poor in metals. The only lead-mines now wrought are at Strontian in Sunart. In these mines were discovered in the last century the rare minerals strontianite and cross-stone. In 1849 the Duke of Argyle discovered near Inverary, a vein of arsenical nickel in mica-slate, which is now worked with favourable prospects.

A barrenness of soil and scanty vegetation prevail chiefly on the higher parts of the mountains, which exhibit great masses of stratified rocks or groups in a columnar form. Some of the glens are covered with large fragments of these, which have been precipitated from the impending cliffs, and consequently they afford scanty pasturage; the greater part of them, however, yield good grass. Others of them exhibit fertility, verdure, and cultivation, for miles, particularly Glendarual, the most prolific valley of the county. Formerly Argyleshire was interspersed with numerous woods, which, uniting with the lofty mountains, formed the most romantic scenery. But these have been almost all cut down or destroyed to make way for the introduction of sheep; and planting has not, except in a few instances, been carried to any considerable extent. Archibald Duke of Argyle and his son planted very extensively in the neighbourhood of Inverary, and several other proprietors have followed their example; nevertheless, one of the most striking features in the aspect of the county is its want of wood. Remains of ancient forests are still very extensive in various places; and these consist chiefly of oaks, ashes, pines, and birches.

The fallow-deer, which formerly abounded in the woods and on the mountains, are now to be seen only in the preserves of a few gentlemen; but red deer are still found in considerable numbers in Glen Etive and in Mull. Roes are pretty numerous in the northern parts of the county, and both species of moor-game are also found in abundance. The black cattle, which in former times ran wild on the mountains, are now entirely confined to the low grounds, where their young are fed in winter by the proprietors. Fish are not at all so abundant as is generally supposed; for although white fish are taken in considerable numbers, particularly in the neighbourhood of Campbeltown, still the quantity is small compared with what is taken on other parts of the Scottish coast; and Loch Fyne is the only inlet of the sea distinguished for its herring-fishery. In 1851 the herring fishery at Inverary produced 35,325 barrels of cured fish, and 4500 barrels of fish sold uncured; while the white fishery (cod, ling, &c.), 255,882 fish; of which, 8658 cwt. were dried, and 5000 cwt. were sold fresh. The number of boats employed that year was 1445, manned by 4689 men, and the fishings gave employment to 6432 persons. (*Report of Fishery Board*, 1851.)

From its situation on the coast, the temperature of Argyleshire is mild, but very moist and variable. The only crops cultivated to any extent are bere or big, oats, and potatoes. The last form the staple food of the people, and they have consequently suffered severely from the recent failures of that crop. Bere is cultivated to supply the numerous distilleries, which afford employment

to a considerable portion of the inhabitants. The chief branch of industry is the rearing of cattle and sheep. The cattle, though of small size, are equal, if not superior, to any other breed in the kingdom, and are in great demand in the markets of the south, to which they are sent in immense numbers. Dairy husbandry is practised to some extent in the southern parts of Kintyre, where there is a large proportion of arable land. In the more elevated tracts, sheep have very advantageously been substituted for cattle. Until the middle of last century, the only sheep in Argyleshire were of the small native race, and their number was inconsiderable; but these have entirely disappeared, and are now to be found only in the most distant islands of the Hebrides. The blackfaced is the species that is now almost universally reared. About the period above referred to, coarse-woolled heath sheep were introduced into the higher and more barren districts; and as it was soon discovered that the scanty herbage of these gloomy mountains could be converted into a much greater quantity of mutton than of beef, besides yielding a valuable article of manufacture, these hardy animals soon spread over extensive regions, upon which cattle could barely subsist in the summer months; and the income of the landed proprietors was augmented in proportion.

The commerce of Argyleshire is very limited, its exports consisting chiefly of raw produce: sheep, cattle, and fish, form at least two-thirds of the whole; and slates, oak bark, and kelp, constitute nearly the remainder. The imports are almost confined to the supply of necessaries, principally oatmeal and flour, and such articles of luxury as habit has rendered scarcely less indispensable.

Notwithstanding its natural advantages, this county is far from being characterized either by wealth or industry: its manufactures are trifling. It was expected that the Crinan Canal, which was cut across the peninsula of Kintyre at an expense of L.140,000, shortening the voyage from the West Highland and Hebridean ports to the River Clyde nearly 200 miles, would cause an influx of wealth to the county; but neither this nor the Caledonian Canal, which gives access from the county to the German Ocean, has answered the expectations of the projectors, or contributed in any great degree to the prosperity of Argyleshire. The introduction of steam navigation has, however, recently given a great impulse to agriculture and industry. There is not now a loch, bay, or inlet of the county, but is in daily, or at least weekly, communication with Glasgow; and cheerful villas and watering-places are rapidly rising on the shores within a convenient distance of the western capital.

This county still contains many ancient monuments, which display the warlike spirit of its former inhabitants. In the course of the eighth and ninth centuries it was conquered, along with the neighbouring isles, by the Danes and Norwegians. For five or six centuries it continued under the dominion of Norway, and during that period was under the direct administration of feudal chieftains, generally of Norwegian extraction, who each maintained an almost independent government. Along with the Hebridean Isles, all the western parts of Argyle became the conquest of the Scottish monarchs in the fourteenth century. Some time after, Macdonald, the representative of this region, obtained leave from the Scottish crown to hold his possessions as a feudatory to that kingdom; but his turbulent spirit involved him and his family in repeated rebellions, which were at last punished by the forfeiture of their estates, which, along with their titles, were bestowed on the Campbells; and these have ever since retained them in peace and loyalty. The county of Argyle gives the title of *Duke* and *Earl* to the chief of this family, who likewise holds several important offices under the crown. The chief of Argyle in former times could on occasion bring 3000 or 4000 fighting-men into the field. This clan is numerous in Argyleshire, and there are a great number of castles and seats belonging to gentlemen who hold of the duke, and not a few of whom claim alliance with his family.

The county returns one member to parliament, and forms a synod with six presbyteries. Inverary, Campbelton, and Oban, are contributory burghs to Ayr. It is governed by a heritable lord-lieutenant (Duke of Argyle), a lord-lieutenant and high-sheriff, about 55 deputy-lieutenants, a sheriff, and four substitutes. Sheriff-courts are held at Inverary, Tobermory, Campbelton, and Fort-William; and circuit-courts, four times a year, at Oban, Lochgilphead, Dunoon, and Bowmore in Islay.

The population of Argyle has been decreasing since 1831, from the extensive emigration that has been going on, principally to Canada. The following is the state of its population since the commencement of the present century, viz., in 1801, 81,277; 1811, 86,541; 1821, 97,316; 1831, 100,973; 1841, 97,371; 1851, 88,567.

ARGYRASPIDES (ἀργυράσπιδες), a name given by Alexander the Great to a division of his army which had bucklers covered with silver. In this he was imitated by Alexander Severus, who had bodies of men called *Argyroaspides* and *Chrysoaspides*.

ARGYRO-CASTRO, a town in Albania, in Lat. 40. 7. N. Long. 20. 13. E. Here the late Ali Pasha built a strong castle capable of lodging 5000 men. The town is estimated by Holland and Hobhouse to contain 20,000 inhabitants. Till 1811, it enjoyed a sort of rude independence. It is now in possession of the Turks.

ARGYROPULUS, JOANNES, a native of Constantinople, was one of the principal revivers of Greek learning in the fifteenth century. He removed to Italy in 1434, where he obtained the patronage of Cosmo de' Médicis, whose son Pietro, and grandson Lorenzo, he instructed in Greek. In 1480 he removed from Florence to Rome, where he was appointed to a philosophical chair, and died in 1486. His principal works consist of Latin translations of Aristotle. He was singularly prejudiced against the Latin authors, and against Cicero in particular, to whom he denied any knowledge of Greek or philosophy.

ARIADNÆA, festivals solemnized at Naxos and Cyprus in honour of Ariadné. Some Naxian writers recognized two distinct persons of this name; one who was married to Bacchus in Naxos and deified after death, the other deserted by Theseus. The festivals of each, accordingly, were attended with rites of a very opposite nature; those of the first being celebrated with music and other expressions of mirth, whereas the latter were observed with a show of mourning. This festival is said to have been instituted by Theseus, to atone for his ingratitude to Ariadne.—*Plutarch. in Thes.*

ARIADNE was the daughter of Minos king of Crete, and Pasiphaë. Falling deeply in love with Theseus when he arrived in Crete to deliver the young Athenians from the Minotaur, she gave him a clue of thread by which he was enabled to escape from the intricate mazes of the labyrinth. Theseus slew the monster, and carried off Ariadne and her young companions; but on landing at Naxos he treacherously abandoned her, though pregnant, and pursued his course. Ariadne, overwhelmed with grief, destroyed herself. According to another tradition, the god Bacchus found her in Naxos, and filled with amazement at her surpassing beauty, made her his wife; and at her death he placed her bridal crown among the stars.

Several versions of this popular story are given in the *Theseus* of Plutarch. It was a favourite theme with the poets of antiquity, and furnished the subject of many exquisite works of ancient art; as also in later times it has employed the pencil of Titian and other eminent masters.

ARIANO, a city of the Principato-Ultra, in Naples, with several churches and convents, a cathedral, and a mountain-fortress. It stands on a steep hill in a pass of the Apennines. It has manufactures of earthenware, and considerable trade in wine and butter. Pop. 12,000.

ARIANS, followers of Arius, a presbyter of the church of Alexandria about the year 315, who maintained that the Son of God was totally and essentially distinct from the Father; that he was the first and noblest of those beings whom God had created, the instrument by whose subordinate operation he formed the universe, and therefore inferior to the Father both in nature and dignity; also, that the Holy Ghost was not God, but created by the power of the Son. The Arians owned that the Son was the *Word*, but denied that the *Word* was eternal. They held that Christ had nothing of man in him but the flesh, to which the Λόγος or Word was joined, which was the same as the soul in us. See Arius.

The appellation of *Arian* has been indiscriminately applied in more modern times to all those who consider Jesus Christ as inferior and subordinate to the Father, and whose sentiments cannot be supposed to coincide exactly with those of the ancient Arians. Mr Whiston was one of the first divines who revived this controversy in the beginning of the eighteenth century. He was followed by Dr Clarke, who published his famous book entitled *The Scripture Doctrine of the Trinity*, in consequence of which he was reproached with the title of *Semi-Arian*. Dr Waterland, who has been charged with verging towards Tritheism, was one of his principal adversaries. The history of this controversy may be found in a work entitled *An Account of all the considerable Books and Pamphlets that have been wrote on either side, in the Controversy concerning the Trinity, from the Year* 1712*; in which also is contained an Account of the Pamphlets written this last year on each side by the Dissenters, to the end of the year* 1719; published in London in 1720.

ARIAS Montanus, a learned Spanish divine, sent to Antwerp by Philip II. of Spain to publish another edition of the polyglott Bible after that of Cardinal Ximenes. After finishing the work with approbation, he returned to Seville, where he died in 1598.

ARICA, a district and town in Peru. It stands on the coast in the vicinity of a vast sandy desert extending to the foot of the Western Andes. The town is in a narrow valley, watered by a small stream, to which it owes its fertility. This valley is 18 miles in length. Arica is one of the few seaports on this part of the coast of South America. Its chief exports are wool, copper, and silver.

ARICINA, in *Mythology*, a surname of Diana, under which appellation she was honoured in the forest Aricine, so called from Aricia, a town of Latium, at the foot of the Alban Mount. Her temple stood on the margin of the lake of Nemi.

ARIEGE, a southern department of France, formed out of the ancient county of Foix, and parts of Gascony and Languedoc. It is bounded on the scuth by the Pyrenees, on the east by the departments of Pyrenees Orientale and Aube, and north and west by that of Haute Garonne. Its subdivisions, with their population, are as under:—

Arrondissements.	Cantons.	Communes.	Population in 1851.
Foix	8	141	92,671
Pamiers	6	114	82,197
St Girons	6	81	92,567
3	20	336	267,435

From east to west its extent is 66 miles; from north to south 49 miles; and its area 1756 square miles.

The departments of Foix and St Girons are mountainous, and contain some of the loftiest peaks in France; as Pic d'Estats, which is 10,811 feet; Montcalm, 10,512 feet; Serre, 9592 feet; Monteleon, 9424 feet; Montvalier, 9120 feet. This mountainous district contains many small valleys, and two principal ones, which are watered by the Ariège and Salat, considerable affluents of the Garonne, and are very fertile and sedulously cultivated. The produce of the lowlands is grain, sweet chesnuts, apples, and peaches; but the vines produce an inferior wine, which is wholly retained for home consumption. The uplands afford abundant pasturage for cattle, horses, mules, and sheep; and the mountain slopes produce fine timber, oak, beech, ash, and pine. The departments of Foix and St Girons yield some copper, and the most valuable iron mines of France, with a considerable quantity of lead, from which silver is extracted; and the streams afford some grain-gold. The principal iron mines are those of Ax, Taracon, and Vic-Dessus. Around the latter are numerous smelting works, which have been actively carried on for ages; and the vicinity is studded with the neat houses of the iron-masters and their numerous workmen, mingled with the remains of feudal strongholds that once were of importance on this frontier of Spain. (T. S. T.)

ARIENZO, a city of Naples, in the province of Lavoro. It stands on a hill, with an ancient castle overlooking it: and contains seven parish churches, a hospital, and 11,000 inhabitants, including the populous suburbs.

ARIES, in *Astronomy*, a constellation of fixed stars drawn on the globe in the figure of a ram. It is the first of the twelve signs of the zodiac, from which a twelfth part of the ecliptic takes its denomination.

Aries. See Battering-Ram.

ARIMANES, the evil god of the ancient Persians. According to the doctrine of the magi, there are two supreme principles—a good and an evil; the first the author of all good, and the other of all evil: the former represented by light, and the latter by darkness, as their truest symbols. The good principle they named *Yezad* or *Yesdan*, and *Ormuzd* or *Hormizda*, which the Greeks wrote *Oromasdes;* and the evil demon they called *Ahriman*, and the Greeks *Arimanes*. Some of the magians held both these principles to have existed from all eternity; but this sect was reputed heterodox, the original doctrine being that the good principle only was eternal, and the other created.

ARIMASPI (Ἀριμασποί), a Scythian people described by Herodotus as *Cyclopes*, living in the gold districts of the Ural Mountains.—Lib. 4, 13, and 27.

ARIOLI, in *Antiquity*, a kind of prophets or religious conjurers, who, by abominable prayers and horrible sacrifices at the altars of idols, procured answers to their questions concerning future events. Isid. *Orig.* lib. viii. cap. 9. These are also called *harioli*, and their operation *hariolatio*. Sometimes they were denominated *aruspices* or *haruspices*. The *arioli* were distinguished by a slovenly dress, disorderly and matted beards, hair, &c.

ARION, a celebrated Lesbian lyric poet and musician, the son of Cyclos of Methymna. After gaining great reputation in Greece, he passed over into Italy and Sicily, where he obtained the public prizes for poetry and music, and amassed considerable wealth during his sojourn in the Græco-Italian and Sicilian states. At length he embarked in a vessel for his native country; but, on the voyage, the crew, to obtain possession of his wealth, conspired to destroy him. The only favour granted to the poet, when he begged for his life, was permission to throw himself into the sea, after performing one of his lyric compositions on the deck of the vessel. A dolphin, it is said, attracted by the music, gambolled around the ship, and receiving the poet on its back, bore him in safety to the shore near Tænarus, whence Arion hastened to the residence of his friend Periander, tyrant of

Arion || Ariosto.

Corinth, a patron of poetry and the fine arts. Arion was well received by Periander, who gave orders to watch the arrival of the ship in which he had embarked. The crew, when questioned where they had last seen Arion, affirmed that they left him well at Tarentum; but Arion appearing suddenly in the garb he had worn before he leapt into the sea, they confessed their villany, and were condemned to crucifixion. The cautious Herodotus, without vouching for its truth, states this to be the tradition of the Lesbians and Corinthians; and adds, that the votive offering of Arion, a bronze figure of a man riding on a dolphin, is to be seen at Tænarus.—*Clio*, 23, 24.

Arion, a fabulous horse, much more famous in poetic history than Bucephalus in that of Alexander. Authors speak variously of his origin, though they agree in giving him a divine one. His production is most commonly ascribed to Neptune.—See Pausan. viii. 25; Apollod. iii. 6.

ARIOSTO, Lodovico, one of the greatest poets of Italy, was born at Reggio in Lombardy, on the 8th of September 1474. His father was Niccolò Ariosto, commander of the citadel of Reggio, and his mother Daria Malaguzzi of that city, where the family still exists. He showed a strong inclination to poetry from his earliest years, but was obliged by his father to study the law—a pursuit in which he lost five of the best years of his life. Having obtained liberty to follow his inclination, he applied himself to literature; intending to study the classics under Gregorio da Spoleti. But after having had the benefit of this learned man's instructions for a short time, during which he read the best Latin authors, he was deprived of it by Gregorio's removal to France as tutor of Prince Sforza. Ariosto thus lost the opportunity of learning Greek, as he intended. His father dying soon after, he was compelled to forego his literary occupations to undertake the management of the family, whose affairs were embarrassed, and to provide for the subsistence and education of his nine brothers and sisters, one of whom was a cripple. He wrote, however, about this time some comedies in prose, and some lyrical pieces. Some of these attracted the notice of the cardinal Ippolito of Este, who took the young poet under his patronage, and appointed him one of the gentlemen of his household. This prince usurped the character of a patron of literature, whilst the only reward which the poet received for having dedicated to him the *Orlando Furioso*, was the question, Where did you find so many stories, Master Ludovic? The poet himself tells us that the cardinal was ungrateful; deplores the time which he spent under his yoke; and adds, that if he received some miserable pension, it was not to reward him for his poetry, which that prelate despised, but to make some just compensation for the poet's running like a messenger, with risk of life, at his eminence's pleasure. Nor was even this miserable pittance regularly paid during the period that the poet enjoyed it. The cardinal went to Hungary in 1518, and wished Ariosto to accompany him. The poet excused himself, pleading ill health, his love of study, the care of his private affairs, and the age of his mother, whom it would have been disgraceful to leave. His excuses were not received, and even an interview was denied him. Ariosto then boldly said, that if his eminence thought to have bought a slave by assigning him the scanty pension of seventy-five crowns a year, he was mistaken, and that he might withdraw his boon —which it seems his eminence did.

The cardinal's brother, Alfonso, Duke of Ferrara, now took the poet under his patronage. This was but an act of simple justice, Ariosto having already distinguished himself as a diplomatist, chiefly on the occasion of two visits to Rome as ambassador to Pope Giulio II. The fatigue of one of these hurried journeys brought on a complaint from which he never recovered; and on his second mission he was nearly killed by orders of that violent pope, who happened at the time to be much incensed against the Duke of Ferrara. On account of the war, his salary of only 84 crowns a year was suspended, and withdrawn altogether after the peace; in consequence of which Ariosto asked the duke either to provide for him, or to allow him to go to seek employment elsewhere. A province belonging to that sovereign, situated on the wildest heights of the Apennines, being then without a governor, Ariosto was sent thither in that character, and remained there for three years. This office was no sinecure. The province was distracted by factions and banditti, the governor had not the requisite means to enforce his authority, and the duke did little to support his minister. Yet it is said that Ariosto's government satisfied both his sovereign and the people confided to his care; and a story is added of his having fallen in, when walking out alone, with a party of banditti, whose chief on discovering that his captive was the poet of *Orlando Furioso*, humbly apologized for not having immediately shown him the respect which was due to his rank.

Although he had little reason to be satisfied with his office, he refused an embassy to Pope Clement VII. offered to him by the secretary of the duke; and spent the remainder of his life at Ferrara, writing comedies, superintending their performance, as well as the construction of a theatre, and correcting his *Orlando Furioso*, of which the complete edition was published only in 1532. He died of a consumption on the 6th of June 1533.

That Ariosto was honoured and respected by the first men of his age is a fact; that most of the princes of Italy showed him great partiality is equally true; but it is not less so that their patronage was limited to kind words. It is not known that he ever received any substantial mark of their love for literature: he lived and died poor. He proudly wrote on the entrance of a house built by himself,

> Parva, sed apta mihi, sed nulli obnoxia, sed non
> Sordida, parta meo sed tamen ære domus;

which serves to show the incorrectness of the assertion of flatterers, followed by Tiraboschi, that the Duke of Ferrara built that house for him. The only one who seems to have given anything to Ariosto as a reward for his poetical talent is the Marquess del Vasto, who assigned him an annuity of one hundred crowns on the revenues of Casteleone in Lombardy; but it was only paid, if ever, from the end of 1531. That he was crowned as poet by Charles V. seems untrue, although a diploma may have been issued to that effect by the Emperor.

The character of Ariosto seems to have been fully and justly delineated by Gabrielle, his brother:—

> Ornabat pietas et grata modestia Vatem,
> Sancta fides, dictique memor, munitaque recto
> Justitia, et nullo patientia victa labore,
> Et constans virtus animi, et clementia mitis,
> Ambitione procul pulsâ, fastûsque tumore.

His satires, in which we see him before us such as he was, show that there was no flattery in this portrait. In these compositions (the interest of which is only equalled by the elegance as well as *naïveté* of the poetry, and the shrewd observation of human nature, we are struck with the noble independence of the poet. He loved liberty with a most jealous fondness. His disposition was changeable withal, as he himself very frankly confesses in his Latin verses, as well as in the satires.

> Hoc olim ingenio vitales hausimus auras
> Multa cito ut placeant, displicitura brevi.
> Non in amore modo mens hæc, sed in omnibus impar
> Ipsa sibi longa non retinenda mora.

Hence he never would bind himself either by going into orders or marrying, till towards the end of his life, when he espoused Alessandra, widow of Tito Strozzi. He had no issue by his wife, but he left two natural sons by different mothers.

His Latin poems do not perhaps deserve to be noticed: in the age of Flaminio, Vida, Fracastoro, and Sannazzaro, better things were due from a poet like Ariosto. His lyrical compositions show the poet, although they do not seem worthy of his powers. His comedies, of which he wrote four, besides one which he left unfinished, are avowedly imitated from Plautus and Terence; and although natives may admire in them the elegance of the diction, the liveliness of the dialogue, and the novelty of some scenes, few will feel interest either in the subject or in the characters, and none will approve the immoral passages with which they are disfigured—a fault, however, less reproachful to the poet than to the audience and patrons of theatrical representations in those days.

Of all the works of Ariosto, the most solid monument of his fame is the *Orlando Furioso*, the extraordinary merits of which have cast into oblivion the numberless romance poems which inundated Italy during the 15th, 16th, and 17th centuries.

The popularity which a poem, now shamefully neglected, the *Orlando Innamorato*, by Boiardo, enjoyed in Ariosto's time, cannot be well conceived, now that the enthusiasm of the Crusades, and the interest which was attached to a war against the Moslems, have passed away. Boiardo wrote and read his poem at the court of Ferrara, but died before he was able to finish it. Many poets undertook the difficult task of completing that magnificent work; but it was reserved for Ariosto both to finish and to surpass his original. Boiardo did not perhaps yield to Ariosto either in vigour or in richness of imagination, but he lived in a less refined age, and died before he was able to put a finishing hand to that part of the poem which he had written under the impulse of his exuberant fancy; while Ariosto, on the other hand, united to a powerful imagination an elegant and cultivated taste. He began to write his poem about 1503, and after having consulted the first men of the age of Leo. X., he published it in 1516, in only 40 cantos; and up to the moment of his death never ceased to correct and improve both the subject and the style. It is in this latter quality that he excels, and for which Italians gave him the name of *Divino Lodovico*. Even when he jests, he never compromises his dignity; and in pathetic description or narrative, he searches the reader's deepest feelings. In his machinery he displays a vivacity of fancy with which no other poet can vie; but he never lets his fancy carry him so far as to omit to employ, with an art peculiar to himself, those simple and natural pencil-strokes with which he gives to the most extraordinary feats a colour of reality which conciliates our reason without undeceiving our bewildered imagination. The death of Zerbino, the complaints of Isabella, the effects of discord among the Saracens, the flight of Astolfo to the moon, the passion which causes Orlando's madness, teem with beauties of every species. The supposition that the poem is not connected throughout is utterly unfounded; there is a connection which, with a little attention, will become evident. The love of Ruggero and Bradamante forms the main subject of the *Furioso;* and every part of it, except some episodes, depends upon this subject. The poem ends with the marriage of these two personages. (A. P—I.)

ARISTÆUS, son of Apollo and Cyrene, who, for the services he had rendered to mankind by his knowledge of all profitable arts, was placed by the gods among the stars.

ARISTANDER, a famous soothsayer under Alexander the Great, over whom he gained a wonderful influence by the good success of his art. He had already had the same employment at the court of King Philip; and it was he who explained better than his brethren the king's dream after his marriage with Olympias. (Plut. *Alex.*)

ARISTARCHUS, a Grecian astronomer of Samos, one of the first who maintained that the earth revolves round the sun. He was the contemporary of Cleanthes, the successor of Zeno. The opinion ascribed to him with respect to the motion of the earth is not to be found in his only existing work, namely his *Treatise on the Magnitudes and Distances of the Sun and Moon.* A Latin translation of the treatise περὶ μεγεθῶν was published by G. Valla, *Venet.* 1498, and another by Commandine, *Pesauri,* 1572. The Greek text, with a Latin translation and the commentary of Pappus, was edited by Wallis, *Oxon.* 1688, and reprinted in vol. iii. of his works. There is also a French translation, with the text, *Paris,* 1810.

ARISTARCHUS of Samothrace, the most famous of Greek grammarians and critics, flourished about 150 years B.C. He received his education at Alexandria under Aristophanes of Byzantium, and was the founder of a school of grammar and criticism that flourished long at Alexandria, and afterwards also at Rome. The young Ptolemy Epiphanes and Physcon were among his pupils. The labours of Aristarchus were directed chiefly to the Greek poets, especially to the works of Homer, his recension of which has been the basis of the text in all subsequent editions down to the present day. In consequence of the ill-treatment experienced by the learned at Alexandria in Physcon's reign, he retired to Cyprus, where he is said to have perished in his 72d year, in attempting to cure himself of a dropsy by excessive abstinence.—See Dr Schmitz in Smith's *Dict. of Greek and Rom. Biogr. and Mythol.*

ARISTIDES, surnamed the *Just*, one of the most illustrious characters of antiquity for purity and integrity, was an Athenian by birth, and contemporary with Themistocles. His father was Lysimachus, a man of middle rank. His character from his youth gave sure promise of that greatness to which he afterwards rose. To a firm, resolute, and placid temper, he added an utter contempt of dissimulation, and an abhorrence of every thing dishonourable. He began very early to meditate on subjects of government, and applied to his studies with the greatest assiduity. He imbibed a strong predilection for oligarchy upon becoming acquainted with the laws of Lycurgus, which excited his admiration, and gave him a distaste for the unlimited democracy then established in his native city. Themistocles, on the other hand, favoured democracy; and it has been said that even at school he was his constant antagonist on that point; but this story is incredible because of the difference of age between the two men. A perpetual opposition to one another in all political points was the consequence of this difference of opinion, when their abilities raised them to several important stations in the state. It is related, that one day having firmly opposed a proposal of Themistocles in the assembly, which in his own conscience he knew to be right, on coming out he exclaimed, "The affairs of the Athenians will never prosper till they throw both of us into the *barathrum*" (the dungeon for condemned criminals).

Aristides was present at the battle of Marathon, B.C. 490, and was next in command among the Athenians to Miltiades; and on that general's proposing to join battle as soon as possible, he seconded his motion with zeal. In the field he distinguished himself by his valour and generosity; and being left after the battle to secure the spoils, he executed his trust with honour and fidelity, bringing all to the public account, reserving nothing for himself. He was elected to the important office of chief magistrate the year following; but, by the art of Themistocles, the high authority he had attained by his merits was at length converted into a means of overthrowing him, and he was accordingly banished by ostracism, B.C. 483. As the Persians were meditating a new invasion of Greece, he employed himself in his exile in encouraging the Greeks to defend their liberties against the invaders. At the critical moment when the hostile fleets were facing each other in the straits of Salamis, Aristides,

though still an exile, suspended all political animosities; and upon understanding that it was the design of Themistocles to fight the Persian navy in the straits, he waited on him in private, proposed an oblivion of all past circumstances, extolled his intentions, and gave him his sincere promise to assist him to the utmost in effecting his designs. There is an anecdote, that Themistocles, some time after the battle of Salamis, acquainted the Athenians that he had formed a scheme which, although it was of such a nature as forbade his public avowal of it to them, was of inestimable advantage to the state. They immediately ordered that he should communicate it to Aristides. It was a project for consuming the whole confederate fleet of Greece by fire, except their own ships; that thus the entire sway of the sea might be left to the Athenian navy. Aristides replied that nothing could be more unjust, and at the same time nothing more advantageous, than the scheme of Themistocles. Upon this the people immediately determined to dismiss any further thought of it. Aristides, who must have returned from exile before the battle of Platæa, was of considerable service in persuading his countrymen, who were elated with their former successes, to submit to the superior power of the Spartans, and in preserving peace and amity between the confederate forces. He acquitted himself with high distinction in the engagement, and was appointed after the victory to determine a very dangerous dispute concerning the honour of the day, which he conferred upon the Platæans, giving up the claim of the Athenians, the Lacedæmonians following his example. On the rebuilding of Athens, he was the first person to promote a law which divided the administration among the citizens at large, and passed a law that the archons should be elected out of the whole body of the people, who had so highly merited the favour of the state.

Upon the continuation of the war with the Persians, Aristides, was sent, along with Cimon the son of Miltiades, to take the command of the Athenian forces in the confederate army. Their mildness and humility, compared with the haughty domineering temper of Pausanias, and other Spartan commanders, so won upon the rest of the allies, that a confederation was formed under the supremacy of Athens, with the joint concurrence of the Ionian states. The nomination of Aristides to lay an equal assessment upon all the states for the purpose of defraying the expense of the war, was a signal proof of the high opinion entertained throughout all Greece of his integrity and justice. The wisdom and impartiality with which he performed this commission gave universal satisfaction. On Themistocles's falling under the displeasure of the ruling party, Aristides would not concur in a capital prosecution of him; and instead of triumphing over an old enemy, he always spoke of him after his banishment with the highest respect.

This great man died about 468 years B.C., according to some at Athens, at an advanced age; others say at Pontus, where he was transacting public business. He was buried at the public expense, his daughters received portions out of the public treasury, and an estate in land was bestowed on his son Lysimachus, in gratitude for the signal services which Aristides had rendered to his country.

ARISTIDES, *P. Ælius*, surnamed Theodorus, a distinguished Greek rhetorician, born at Adriani in Mysia about A.D. 117. After studying at Athens under Herodes Atticus, he travelled through Egypt, Greece, and Italy. Though his health was extremely delicate, he pursued his rhetorical studies with unremitting assiduity, and acquired so great a reputation that statues were erected in his honour by several of the states he visited. His overweening estimation of his own abilities, however, induced some persons to underrate his merits, and exposed him to frequent enmities. He settled at Smyrna; and when that city was ruined by an earthquake A.D. 178, the eloquence of his appeal induced M. Aurelius to assist the citizens in restoring it. In gratitude for this service they would have heaped honours on Aristides, but he declined to receive anything but the office of priest of Asclepius, which he held till his death, about A.D. 189. His *Sermones Sacri* contain several curious passages respecting the cures of the sick in temples, which have excited considerable attention in modern times by their apparent resemblance to certain effects said to be produced by Mesmerism, or, more properly, *Hypnotism* or nervous sleep. Fifty-five of his orations and declamations are extant, and two treatises on rhetoric, of little value. A complete edition of his works was published by W. Dindorf, Lips. 1829, 3 vols. 8vo.

ARISTIDES, *Quintilianus*, the author of a valuable treatise upon music, who probably lived in the first century of our era. The work is printed in the collection of Meibomius, entitled *Antiquæ Musicæ Auctores Septem*, Amst. 1652.

ARISTIDES, a painter contemporary with Apelles, flourished at Thebes about B.C. 360–330. He was the first, according to Pliny, who expressed character and passion, but was not remarkable for softness of colouring.

ARISTIPPUS, the founder of the Cyrenaic sect of philosophy, was the son of Aretades, and born at Cyrene in Libya. He flourished about 380 B.C. The great reputation of Socrates attracted him to Athens, where he attended the discourses of that great teacher, whose practical philosophy he freely modified to suit the easy and sensual bent of his own mind. His free and luxurious life was in accordance with his distinctive doctrine, that Pleasure was the highest good of man. Though possessed of a competent estate, he was the only disciple of Socrates who took money for teaching. Upon leaving Socrates he went to Ægina, where he lived even more luxuriously than before. Socrates made frequent attempts to reclaim him, but in vain. In Ægina Aristippus became acquainted with Laïs, the famous courtezan of Corinth, for whose sake he took a voyage to that city. He continued at Ægina till the death of Socrates. After this he visited the court of Dionysius, tyrant of Sicily, where he spent a considerable time, leading a life of unrestrained enjoyment. On his return to Cyrene to visit his daughter Arete, he fell sick and died at Lipara.

Many of his apophthegms are preserved. To one who asked him, what his son would be the better for being a scholar, "If for nothing else," said he, "yet for this alone, that when he comes into the theatre one stone will not sit upon another." When a certain person recommended his son to him, he demanded 500 drachmas; and upon the father's replying that he could buy a slave for that sum, "Do so," said he, "and then you will be master of a couple." Being reproached because, having a suit of law pending, he fee'd a lawyer to plead for him, "Just so," said he, "when I have a great supper to make I always hire a cook." Being asked what was the difference between a wise man and a fool, he replied, "Send both of them together naked to those who are acquainted with neither of them, and then you will know." Being reproached for receiving money of Dionysius, at the same time that Plato accepted only a book, "The reason is plain," said he, "I want money and Plato wants books."

The doctrine of Aristippus is summed up in the word *Enjoyment*. The final end of man's existence, according to him, is *the Good*. Pleasure and pain are the two poles of his being,—the one is essentially good, the other essentially evil. To follow the one and flee the other is the whole duty of man. Pleasure is essentially present; the hope of future good being always conjoined with fear. Free and immediate abandonment to all the instincts of nature alone leads to true happiness. Herein the doctrine of Aristippus differs from that of Epicurus, who inculcated the necessity of a wise calculation of consequences, and a choice

of pleasures. Aristippus, again, held that all pleasures were equally good, whatever their origin, those of the body, as more immediately realized, being higher in degree.

Of the numerous works of Aristippus, of which a list is given by Diogenes Laertius, none has been preserved. M. Luzac, in his *Lectiones Atticæ*, has shown that he was not the author of the treatise on the *Luxury of the Ancients*, frequently ascribed to him; nor of the *Epistles* given as his in the Socratic collection of Leo Allatius.—See F. Mentzius, *Aristippus, &c.*, 4to, Halle, 1719; Batteux, *Développement, &c.*, in vol. xxvi. of the *Mém. de l'Acad. des Inscript.*; Kunhardt, *Diss. Philos. Histor. de Aristipp. Phil. Mor.* 4to, Helmst, 1796; and Wieland's *Aristippus*, 8vo, Leipsic, 1800–2.

ARISTO of Chios, a Stoic philosopher, the disciple of Zeno, flourished about 290 years before the Christian era. He differed but little from his master Zeno. Rejecting logic as of no use, and natural philosophy as being above the reach of the human understanding, he confined himself exclusively to morals. He founded a sect apart from that of his master, which had but a brief existence. To him is attributed the saying commented on by Epictetus and Antonine, that "the wise man is like a good comedian, equally capable of playing the part of Agamemnon, or of Thersites."—See Cic. *de Leg*, i. 13; *de Fin.* ii. 13; iv. 17; Diog. Laert. vii. 160, &c. Another philosopher of the same name, a Peripatetic, was a native of Ceos, and lived about 260 B.C. Cic. *de Fin.* v. 5; Diog. Laert. v. 70, 74; vii. 164.

ARISTOBULUS of Cassandria, one of the generals of Alexander the Great; wrote a history of his expedition, of which but a few imperfect fragments remain. He was regarded as a writer of high veracity.

ARISTOBULUS, a Jew of Alexandria, who lived about the middle of the second century. He is remarkable as having, along with Philo, set the example of that mode of interpretation which sought to find a harmony between the pagan mythology and the doctrines of the Hebrew Scriptures. He is said to have forged in the works of profane authors numerous passages tending to prove that they had borrowed from the Bible. This pious fraud deceived many of the Christian fathers and of the heathen writers. Aristobulus wrote pure Greek, unmixed with Hebrew idioms.

ARISTOBULUS. See JEWS.

ARISTOCRACY (ἀριστοκρατία, *the rule of the noblest*). See GOVERNMENT.

ARISTOGITON, a famous Athenian, who, with Harmodius, killed Hipparchus, tyrant of Athens, about 513 B.C. The Athenians erected a statue to him. See HARMODIUS.

ARISTOLOCHIEÆ, a natural order of Monochlamydean plants, of which the chief genera are Aristolochia, and Asarum, the medicinal qualities of which are purgative and emetic.

ARISTOPHANES, a celebrated comic poet of Athens. He was contemporary with Plato, Socrates, and Euripides; and most of his plays were written during the Peloponnesian war. His imagination was warm and lively, and his genius particularly turned to raillery. He had also great spirit and resolution, and was a declared enemy to the war party, and to all the numerous reformers in politics and religion. The Athenians suffered themselves in his time to be governed by men who had no other views than to make themselves masters of the commonwealth. Aristophanes exposed the designs of these men with great wit and severity upon the stage. Cleon was the first whom he attacked, in his comedy of the *Knights*, performed in B.C. 425; and as there was not one of the comedians who would venture to personate a man of his great authority, Aristophanes played the character himself, and with so much success, that the Athenians obliged Cleon to pay a fine of five talents, which were given to the poet. He described the affairs of the Athenians in so exact a manner that his comedies may be regarded as a nearly faithful picture of his time. For this reason, when Dionysius king of Syracuse desired to learn the state and language of Athens, Plato sent him the comedies of Aristophanes. He wrote above 50 comedies, but there are only 11 extant which are perfect: these are, *Plutus, the Clouds, the Frogs, the Knights, the Acharnians, the Wasps, Peace, the Birds, the Ecclesiazusæ or Female Orators, the Thesmophoriazusæ or Priestesses of Demeter*, and *Lysistrata*. *The Clouds*, which he wrote in ridicule of Socrates, is the most celebrated of all his comedies. Having conceived some aversion to the poet Euripides, Aristophanes satirizes him in several of his plays, particularly in his *Frogs* and his *Thesmophoriazusæ*. He wrote his *Peace* in the 10th year of the Peloponnesian war, when a treaty of 50 years was concluded between the Athenians and the Lacedæmonians, though it continued but seven years. The *Acharnians* was written with a view to set forth the blessings of peace, and to dissuade the people from intrusting the safety of the commonwealth to such generals as Lamachus. Soon after, B.C. 415, he represented his *Birds*, by which he pictured to the Athenians the deplorable condition of their state and their political situation. The *Wasps* was written after the loss in Sicily, which the Athenians suffered from the misconduct of Chares. He wrote the *Lysistrata* when all Greece was involved in war; in which comedy the women are introduced debating upon the affairs of the commonwealth, when they come to a resolution not to go to bed with their husbands till a peace should be concluded. His *Plutus*, and other comedies of that kind, were written after the magistrates had given orders that no person should be exposed by name upon the stage. He invented a peculiar kind of verse, which was called by his name, and is mentioned by Cicero in his Brutus; and Suidas says that he also was the inventor of the tetrameter and octameter verse.

Aristophanes was greatly admired among the ancients, especially for the true Attic elegance of his style. The time of his death is unknown; but it is certain that he was living after the expulsion of the tyrants by Thrasybulus, whom he mentions in his Plutus and other comedies.

There have been many editions of the works of Aristophanes. The *editio princeps*, printed by Aldus at Venice in 1498, in folio, is a rare and beautiful volume. Among the principal editions are that of Brunck, Strasburg, 1781–3, 4 vols. 8vo, and Oxford, 1810; that of Bekker, London, 1829, 5 vols. 8vo, and that of Dindorf, Oxford, 1835–37, 3 vols. 8vo (vol. 4 Scholia Græca); and Paris, 1838, 1 vol., Lex. 8vo, *Gr. et Lat.* Madame Dacier published at Paris, in 1692, a French version of Plutus and of the Clouds, with critical notes, &c. Theobald likewise translated these two comedies into English, and published them with remarks. Cumberland gave a translation of the Clouds in his *Observer*, accompanied with an able view of the life and genius of the author. A translation of the greater part of Aristophanes, with introductions of considerable length, has been published by Mr Mitchell, 2 vols. 8vo, Lond. 1820–22. Mr Mitchell has also published valuable annotated editions of several of the plays. There are also translations, partial or complete, by Walsh, Wheelwright, an *Oxford Graduate*, and Hickie (Bohn's Class. Lib.)
